THE CANADIAN ENGINEER

ESTABLISHED 1893

Issued Weekly in the interests of the Civil, Mechanical, Structural, Electrical, Marine and Mining Engineer, the Surveyor, the Manufacturer, and the Contractor.

Index to Volume (16) 7

(JANUARY-JUNE, 1909)
Aug. - Dec. 1909

The volume of editorial matter has increased to such an extent that it has been found necessary to issue indexes every six months. Henceforth a new index will appear in June and December.

CANADIAN WATER POWER AND ITS ELECTRICAL PRODUCT IN RELATION TO THE UNDEVELOPED RESOURCES OF THE DOMINION.*

Canada with a small population and insufficient capital has nevertheless held a foremost position in the products of the forests and the fisheries, as well as in the quality of those cereals and fruits which attain their highest development in a northern latitude. In live stock she has not suffered by comparison with any other portion of this continent, while in dairy products she is pre-eminent. If she has not, until recently, made much progress in mineral development, it has been more from want of money than of mines. If she has been long in attaining a position as a manufacturing country, it is accounted for by the fiscal and financial conditions of a sparsely-settled country, the smallness of a home market, and the competition of greater capital and out-put, and therefore cheaper production elsewhere. Amongst the many partially developed resources of Canada, perhaps there is none more widespread or more far reaching in future results than her unsurpassed water power. The value of this has been enormously enhanced, first by the expansion of the wood pulp manufacture, and the introduction of electro-chemical and metallurgical industries for which this country possesses the raw material; and, more recently, by the revolution which has been brought about by success in transmitting the energy of water falls from remote and inconvenient positions to those where the work is to be done. Electrical transmission brings the power to the work, and when the prime mover is water, we have the cheapest power, and perhaps nearest approach to perpetual motion which it is possible to obtain—one which is always "on tap," and, like gravity, maintained without cost and applied without delay.

An examination of any good map of our broad Dominion reveals, as its most striking feature, an extraordinary wealth and remarkably uninterrupted succession of lakes and rivers, suggestive of ample rainfall, the first great requisite in the occupation of any country. This feature would be still more impressive if all the waters could be shown on the map. Over large areas only the more important rivers have been explored and delineated; while in the surveyed districts many are necessarily omitted to leave room for other information to be given. These rivers and lakes have been the most important factors in the settlement of the country, as they formed the earliest lines of approach for the penetration and exploration of the interior, and for the exploitation of our forests. The lumberman followed the trapper and the fur trader, the axe supplanted the rifle, and thus the country was opened up by men who knew not only where to begin, but, by their calling, were best equipped as pioneers. The frontier, where not already occupied by the French, was necessarily rapidly settled in the first place by the Loyalists of 1776, who could not stand upon the order of their departure after their homes were confiscated. These found the rivers their earliest friends, from whence they obtained the means of shelter and of employment in the only industry by which money could then be obtained, viz., the floating of timber and potash to Montreal and Quebec.

Over a length of several thousand miles between Labrador and Alaska and over a width of several hundred miles, there is an almost continuous distribution of lakes, lakelets and rivers—the lakes of varied outlines, dimensions and elevations above sea level, and many possessing facilities for the storage of their flood waters. This power of storage has been largely taken advantage of by lumbermen to retain the needed supply for their spring "drive," into the main stream. In many places the outlet from the lake, or the connection between a chain of lakes, is a narrow cleft in rock where an inexpensive dam will hold back the water supplied by the winter's accumulation of snow. With the exception of her prairie region, the rivers of Canada differ from the Mississippi, Missouri, and Ohio, and the larger part of their tributaries, in that they are not naturally navigable from their mouths, or above

*Presidential Address read before the Society, May 23rd, 1899, by Thos. C. Keefer, C.M.G., President of the Royal Society of Canada.

tidal influence to any considerable extent, except in detached sections; while the former are navigable for thousands of miles and are therefore without water power. Those great western rivers flow upon a nearly uniform grade of a few inches per mile, whilst the St. Lawrence and its tributaries are interrupted by rapids, chutes and cataracts, affording a great variety, quantity and quality of water power.

In the United States, between the Atlantic coast and the Rocky Mountains, as far south as the Gulf of Mexico and as far north as the Dakotas (with the exception of part of New York and New England), there is an entire absence of lakes; while throughout Canada, north of the St. Lawrence and stretching north-west toward the Mackenzie river basin, these are innumerable, in fact have never been numbered, and thousands of the smaller ones have never been represented on any map. The upper sections or sources of most of the Canadian rivers are chains of lakes, occupying in many instances the greater portion of the water course. These head waters are often upon nearly the same elevation and interlocked with the sources of other rivers flowing in opposite or different directions, and separated by narrow necks of land at a low divide, rendering diversion from one to another possible, a feature which has in some places been utilized by lumbermen—fearless of any legal injunction. This terrace-like profile of the rivers and their frequent expansion into lakes, often dotted with islands, not only enhances the beauty of the scenery, but, for utilitarian purposes, constitutes a series of elevated natural mill ponds, containing latent power of unknown extent and value, awaiting that demand upon them which is now being made in consequence of the discovery that our second-rate forest growth which has hitherto served chiefly to ornament their shores and islands has become the most important, and can be ground into pulp and rolled into paper to meet the ever-increasing demands of the newspaper, the bookmaker, and the innumerable forms into which wood pulp can be compressed for useful or ornamental purposes—or as a substitute for wood or metal. These steps from high to lower levels in every rivulet, branch, tributary or main stream of nearly every one of our northern rivers produce more or less broken water which never freezes over but remains open during the coldest weather, giving an alteration of closed and open water sections, of ice-covered lakes and of broken water in rapids, which may cover miles in extent, as well as at chutes or cataracts with more or less open water above and below them.

It is an interesting question for specialists to determine what effect, if any, this often large percentage and almost general distribution of open water during the coldest weather (of which every stream large or small has a portion), may have in modifying the extremes of temperature in these northern latitudes. When all the ground is frozen solid and covered with a deep mantle of snow, extending over the lakes and checking increasing thickness of their ice covering, large bodies of water are impounded and maintained at a temperature above the freezing point, although there may be fifty degrees of frost in the air, and are constantly poured forth into this frigid atmosphere. It is conceded that our Great Lakes modify the temperature of their border lands, and although these open water spaces in our northern rivers may be inferior in surface, they exist on every river having rapids or falls, and extend over such a vast field that their aggregate area must be very large. Unlike the Great Lakes these open spaces are constantly receiving fresh supplies of warmer water to temper the severity of the air. Such "breathing holes" (as they are sometimes called), are necessarily comparatively shallow, and are the only places, after all other water is frozen over, where "anchored" ice is formed and found. This differs from the lake ice in that the latter melts where it freezes, while anchor ice, when compelled by milder weather to let go its hold upon the bottom, rises, and is immediately drawn under the fixed ice below, and does not dissolve until the river breaks up in the spring. The latent heat of water disengaged in freezing—which process occurs so frequently during the five months of winter—is imparted to the atmosphere, but is not again absorbed by melting ice, as would be the case in lakes, or in deep, sluggish rivers. Again radiation is supposed to play an important part in "anchoring" the floating particles of ice to the river bottom, which is said to be cooled so rapidly by the ice-laden current above it as to become frozen, and then begin to attract the passing ice needles, and fix them to its bed. If mother earth, in mid-winter, contributes any of her impounded heat to the outer atmosphere, these almost innumerable unfrozen spaces certainly offer great facilities for giving vent to her suppressed emotions.

From the Straits of Belle Isle to Montreal, and thence ascending the Ottawa, the tributaries of the St. Lawrence and of the Ottawa descend, through the Laurentian region, from elevations of 1,800 to 1,000 feet above tide, and debouche within a few miles of each other, except immediately about the Saguenay. In many cases they bring their principal cataracts very near their outfall, notably in the case of the famous Falls of Montmorency, which, leaping directly into the St. Lawrence from a height of 250 feet, are utilized to light the streets and drive the tram cars of Quebec. Somewhat similar conditions exist on the south shore of the St. Lawrence until the Richelieu river (the outlet of Lake Champlain), is reached, where at Chambly, water power is about to be used to send the electric current into Montreal, in competition with steam, and with a similar water power from the Lachine Rapids. The divide between the St. Lawrence and the Ottawa is studded with lakes west of the Rideau Canal, a principal outlet for which—on the south—is the river Trent discharging into the Bay of Quinte, with large mills and much undeveloped water power at its mouth; and on the north, some half a dozen important tributaries discharging into the Ottawa. At Sault Ste. Marie, a water power canal fed from Lake Superior supplies the largest pulp mill yet erected in Ontario, and a similar work at the Lake of the Woods (which lake is 1,000 feet above tide), gives power to the largest flour mill in the Dominion. The waters of the Winnipeg river (the outlet of the Lake of the Woods), descend about 300 feet, unused, into Winnipeg Lake, adjoining Lake Manitoba, from whence the water system extends to the Saskatchewan, and thence via Athabasca, the Great Slave, and the Great Bear lakes, to the Arctic circle.

No reference has been made to the long established

water power in the older districts, on the Saguenay, or those between Montreal and Quebec, and upon the Ottawa, nor to the more recent and extensive pulp and paper establishments—it being the object of this paper to draw attention to the continuity and broad distribution of water power across the continent, on Canadian territory, and to the unnumbered natural reservoirs of water at elevations which impart to them latent powers for the future development of this country. British Columbia has not been included in this field, because its occupied portion is separated by our great prairie region from the lake system of Eastern Canada, which system is deflected toward the North-West at the Lake of the Woods. This province is by no means deficient in water power, although it has been little used as yet where mines are on high levels, and because steam could be more readily applied. On the other hand, it is the only province in which hydraulic mining is in operation; and where gold is found in quantity sufficient to warrant the great outlay of capital necessary in connection with that system. In the Kootenay, water wheels, with or without electrical transmission, are necessary for water power, in order to mine, pump, and crush the gold-bearing rocks; but in the Cariboo district, water power is applied in the simplest form, without wheels or wires, by direct pressure from a nozzle, as is done in Ottawa from a fire hydrant While the mountains south of the Canadian Pacific Railway are rich in metallic veins, the region north of this railway, extending into the Arctic Circle, appears to be a veritable land of Havilah, a continuous "Placer" gold field, in which much of the precious metal is to be obtained by hydraulic mining, wherever that is practicable.

This gold field, over a thousand miles in extent between the Fraser and Yukon rivers, and of unascertained width, has been exploited at Cariboo, (from whence fifty million dollars has been taken), at Cassiar and Omenica, and recently at Atlin, all in British Columbia—as well as in the far-famed Klondyke, in the Yukon district, said to be the richest gold field in the world. Water, in whatever way it is used, is necessary to the recovery of this gold, but in many places water power alone will profitably unearth it from its hidden recesses. This is collected in quantity from lakes, and reservoirs on the high levels, and carried for miles by ditches, aqueducts and flumes, to the banks of a primeval, deserted river channel, at the bottom of which, under forest-covered clay banks, lies the auriferous gravel studded with boulders and resting on the bed rock. Under a head of about 300 feet "six-inch rapid fire," hydraulic guns are pointed against the bank, breaking down the earth, uprooting trees, scattering boulders and washing out the gold—which remains in the traps set for it in the bottom of the sluices after all else has been carried off by the power of the water. These "machine guns," called "giants" and "monitors," are models of simplicity as well as of ingenuity and efficiency. While working they are great consumers of water—and can only be used when the ground is unfrozen, but this season is generally sufficient to use up all the water which can be collected at the necessary elevation. It requires at least two men to hold and direct the force of the issuing stream from an Ottawa fire hydrant, but a boy can direct the movement of a stream, twenty times greater in quantity and fifty per cent. stronger in pressure, as it rushes forth from the nozzle of one of these "giants"—which is fixed to a loaded platform, and moved forward as the bank in front of it melts away. A thin, short tube, of larger diameter, projects beyond the nozzle to which it is fixed by trunnions, so that the tube can be moved independently, both horizontally and vertically, to touch the issuing stream, which immediately recoils from the obstruction moving the "giant's" nozzle in the opposite direction. Thus a boy "behind the gun" can control its movement and compel the "giant" to fall back upon his own resources for motive power.

It is impossible to give anything but an approximate estimate either of quantity or value of the available water power over so vast an area, becuse the first would involve the survey of every power site; and, as to the second, the value begins when the power is wanted. All which now can be done is to state the conditions and endeavor to estimate the quantity, hypothetically. What is needed for an estimate is the quantity of water and the amount of fall which can be relied upon at the site for each power. To get the first, a measurement of the minimum flow at each point would be necessary in low water years, and for the second, some local knowledge as to river levels, back water, etc. In the absence of such surveys we must fall back upon the average rainfall of the whole region as far as that can be procured for any time, and assume the proportion of this precipitation (of rain and snow), which, after deductions for evaporation, the demands of vegetation, or infiltration, would reach the wheels. An allowance must also be made for that portion of the rainfall which may be carried off in floods. The area over which this precipitation would be in reach for water power purposes would embrace all the main land of Canada south of the St. Lawrence as well as all north of it in the St. Lawrence valley, and so much of the Hudson Bay watershed as can be utilized, or imported by transmission. As regards the power of the water thus estimated, we must embark in a much more speculative estimate as to the average fall which should be assigned to it for the whole region. We have in the undeveloped districts some scattered meteorological observations to assist us in estimating probable rainfall, and we have also a few barometrical observations giving the height above sea level of summit waters. On lower levels we have more numerous rain gauges, and summit levels ascertained by railway surveys.

For the whole river the total fall may be less than 100 feet, as in the case of the French river, which has Lake Nipissing for a mill pond, or rise to 1,500 feet or more as at the rivers below Anticosti. In the case of the French river (which is the lower part of a longer stream), we have surveys, and know that its whole fall can be utilized, as would be done if it is made navigable by locks and dams. In the others (where no surveys have been made), some will be more or less like French river, while at others only a portion of the total fall upon them may be profitably utilized. The most valuable will be those which, like Montmorency, bring all their water with sufficient head to the point where it is worth most. The upper sections of the rivers will be the least valuable, as having less water and being more remote until reached by a new railway, or a

transmission wire. We can therefore only state a hypothetical case especially as to the power to be assigned to the available water. Where the rainfall is known, the proportions which reach the streams have been ascertained, in the construction of reservoirs for water supply and other purposes. The chief difficulty with respect to the quantity of water is the want of rain gauges over so great an extent of unoccupied territory. Assuming therefore an average annual precipitation of twenty-four inches and taking one-half of this as available for water power, every ten square miles would yield an average of nearly one horse power for every foot of fall. A million square miles (and there is much more), would give nearly 100,000 horse power for every foot of fall; as there would be several hundred feet of fall which could be utilized, our water power must be immense—and commensurate with this country in other respects.

The above applies only to the tributaries of the St. Lawrence and the Ottawa, and to the Hudson Bay watershed so far as that may be utilized. The Canadian portion of the water power of the St. Lawrence, from Lake Superior to Montreal, in which there is a fall of 546 feet, is not included, being below the level of the tributaries. We have measurements of the flow in both the St. Lawrence and the Ottawa in cubic feet per second, as follows:

	c. ft. per sec.
In St. Mary's river, outlet of Lake Superior.....	80.000
In St. Clair river, outlet of Lake Huron.....	225,000
In Niagara river, above the falls.....	265,000
In St. Lawrence river, above the rapids.....	300,000
In Ottawa river, above Lake of Two Mountains...	35,000

Canada's share of the St. Lawrence water power from Lake Superior to Montreal would be about ten million horse power. Canada has half the water of the St. Lawrence from Lake Superior to Cornwall, and all of it between Lake St. Francis and Montreal; but only a portion of this half could be utilized—and this would apply more or less to the Ottawa and other rivers, where all the power could not be utilized without an expenditure probably beyond its value. The power at Niagara has been estimated at seven million horse power, from less than half of the fall between Lakes Erie and Ontario, but the flow of the Niagara river, as given above, does not support so high an estimate. The whole of this fall (over 320 feet), can be utilized on the Welland Canal, but the quantity is comparatively insignificant, from the limited channel and necessarily low velocity of the current in it. In like manner the whole fall upon our canals in the St. Lawrence can be utilized subject to the limitations imposed by the requirements of navigation. Because these canals have not had the work for which they were intended, they have in some cases become mill races rather than slack water channels. This has been the less felt, hitherto, on account of the lightness of their west-bound traffic, the strong current toward the mills being in favor of the deeper laden east bound craft, thus incidentally compensating for a violation of canal maxims.

While water power was at first the only substitute for the windmill in new countries, and its economy as well as superiority has always been recognized, several causes have contributed to limit its more general application. Before the invention of the turbine in the first half of the present century, heads exceeding about seventy feet could not be utilized on account of the comparative weakness and excessive cost of wheels of large diameter. In these days of structural steel, and "Ferris" wheels, this difficulty could be overcome; but, with the turbine, the conditions are reversed, the higher the head the less the size and cost of wheels, so that the most valuable water powers were the most cheaply utilized in this respect. A previous check to greater extension of water power was given in the latter part of the last century by James Watt's discovery of the steam engine, which by bringing the power to the work, to the city, and to the mine, revolutionized industrial conditions. A still greater revolution has recently occurred which brings water power to the front again, by its amalgamation with electricity, whereby its economical power is transferred to the work, over many miles of distance, upon a single wire. Within the last ten years high voltage electricity has been firmly established with annually increasing power of extension, and this has brought Canada into the first rank of economical power-producing countries. Water is thus represented by a power to which it can give birth, but which is superior to its own, in that, wherever transplanted, it can do nearly all the parent power could do, as well as give light, heat and greater speed; moreover it has given rise to industries only possible with abundant cheap electricity. What is more important to us is that such industries are those for which Canada possesses the raw material, but which, without water power, she could not engage in. There are important industries in which we have for some time utilized water power, for which electricity is not indispensable; but which equally require large amounts of cheap power, and are capable of indefinite extension: but while these may not need the intense electric current necessary for electro-chemical industries, they will find electrical transmission of inestimable value in many situations; while, for lighting and heating purposes, water power is invaluable to all. Heretofore we have cut our spruce into deals and exported it to Europe, and more recently into pulp wood and exported that to the United States; but, manufactured by our water power into paper, the raw material would yield this country ten times the value it is now exported for. The extension of railways, combined with electrical transmission, will promote the local manufacture of such wood products (including all valuable hardwood), as can bear transportation; thus giving the largest amount of local employment, as well as tonnage to the railway; and delivering us from the position of "hewers of wood" for other countries.

(To be continued).

AN ELECTRICAL CENTRE.

We speak of the natural resources of Canada in a vague way as we do of the sands of the sea, and with no more clear conception of what we are saying. It is sometimes a surprise to us when something comes up which gives us a more definite idea of what are our resources. Such is the map issued under the authority of the Board of Trade of Ottawa, which shows that within a radius of 45 miles from Ottawa city there is water power which at low water amounts to 917,693 h.p., and at high water to 3,317,630 h.p. Of this half a million h.p. (maximum flow), is within four miles of

the centre of the city. The rest of this vast power is distributed over the territory surrounding the city in about 42 units of from ten to one hundred thousand horse power. The compilation of the water powers in the area included in this map are from reports, estimates, and information given by the following gentlemen at the request of the Ottawa Board of Trade: T. C. Clark, C.E.; Walter Shanley, C.E.; Thomas C. Keefer, C.E.; George P. Brophy, C.E.; Robert Surtees, C.E.; Henry A. F. McLeod, C.E.; Frank A. Hibbard, C.E.; David Scott, C.E.; Henry Carre, C.E.; Andrew Bell, C.E.; J. H. Matte, C.E.; Andrew Holland, Ottawa; George L. Dickinson, Manotick; Alex. McLaren, Ottawa; W. C. Edwards, M.P., Rockland; R. McRitchie, Bryson; J. A. Cameron, Thurso.

A feature of these water powers, which makes them very valuable, is that almost all are so situated as to have many lake expansions, and all offer opportunities for the creation of artificial reservoirs so that the mean flow may be made regular. In many cases these dams have been already built by the lumbermen and are very important works; one on the Gatineau river gives a depth of five feet in a lake 30 miles long. To those who think of Ottawa as either the Washington of the North, or the seat of the lumber trade, we must point out that both are correct but incomplete descriptions of that city. It is the centre of a very rich agricultural and mineral country, and in addition to its lumber manufactures must very soon take a leading position in other lines of production. On every side of the city iron mines of great value are found. At Ironsides, to the North of Ottawa, one of the earliest attempts at iron smelting was made, but it was found unprofitable, and abandoned. At Bristol, to the West are iron mines which are very rich and have successfully shipped ore in spite of adverse duties in the United States. At Calabogie, to the South-west, is an iron mine which was sold for $100,000 a few weeks ago. These are all within the 45-mile radius, and all have communication by rail with the city. Some ten miles up the Ottawa river beyond this line are situated the galena mines, which have attracted so much attention in the past two years, and are now being profitably worked. Here are also four water powers on the Ottawa river aggregating one million horse power. In the electrical age, as next century will probably be called, Ottawa will undoubtedly be one of the industrial centres of the continent.

THE PROTECTION OF LOW TENSION WIRING AGAINST DANGEROUS HIGH POTENTIAL CURRENTS *

BY W. J. PLEWS, MONTREAL.

All persons in connection with electrical supply companies, especially in lighting service by alternating currents, have long recognized the necessity of some reliable apparatus to prevent low tension service wires inside buildings from becoming a possible source of danger to human life, or as regards fire, in event of contact with high tension conductors. That this condition often exists, and that the danger therefrom can hardly be overestimated, is a well known fact to all electricians who have had experience with alternating current systems. Some years ago, the principal element of danger was the liability of transformers to break down between the primary and secondary coils. Of late, however, conditions have changed considerably, the more recent types of transformers being a vast improvement on the older ones. While the contingency as regards transformers is not now so great as in former years, the change in the system of secondary distribution involving as it does the use of large secondary units and a net-work of wires covering a great area, has given rise to another and if anything a more important element of danger, namely, the increased liability of accidental contact between high and low tension conductors. This change in secondary distribution has been rendered necessary from an economical standpoint, and as it is not at all likely that anyone will revert to the old system, the proper course seems to be the protection of individual equipments. The contingencies previously mentioned have proven a frequent cause of fire, and in some instances have resulted in fatal accidents. Recognizing these dangers, various earthing devices have been contrived to cope with the difficulty. It seems, however, that the idea has been to afford protection from the breaking down of transformers only, by means of blowing the primary fuses, the inventors apparently not having taken into consideration the contingency of accidental contact between local and foreign conductors, whereby a large volume of current at a high potential may flow over the secondary apparatus and destroy both it and the protective device, in which event the protective device itself would probably become a source of fire. Several of the cases which have come under the observation of the writer, wherein conditions as mentioned have existed, have been of such a nature that any earthing device, depending upon the blowing of a fuse for its action, would have been a positive fire hazard. One instance in particular was a cross between a fallen secondary and a trolley wire. In this case had there been any device of the type mentioned, a volume of current would have flowed through the apparatus sufficient either to destroy it or blow the secondary fuses; this latter occurring, it is reasonable to assume that the high tension current would have maintained an arc across the terminals of the cut-out (one such as generally used for low tension wiring), and produced disastrous results. As far as the writer's knowledge extends, the principle, common to all safety devices of this nature, heretofore developed, has been to disconnect the local system from the source of danger by means of blowing fuses. This principle appears to be radically defective, the blowing of a fuse under such conditions being an uncertain element, attended at times with undesirable results.

In any apparatus designed to protect local low tension systems from currents of higher potential than they are constructed for, or expected to carry, it would seem more rational to employ a device that will automatically and instantaneously disconnect the high tension current from the low tension system to be protected, without depending upon the uncertain action of fuses. It is also believed that a device of this nature should be one in which the amount of current necessary for its successful operation is a known quantity, and that this quantity be as small as possible, so as to avoid dangerous arcing. Considering the matter from this point of view, the writer believes that an apparatus can be constructed which will embody the desirable characteristics, and it is to this possibility that your attention is respectfully invited. One form of such an apparatus, which is on exhibition here, is similar in action to a double pole knife switch, and is so constructed as to automatically open the circuit instantaneously, whenever the low tension wiring is brought into connection with conductors charged with dangerous high potential currents, either through a break-down in a transformer, or a cross between secondary and primary, or other high tension conductors. The great advantage claimed for this apparatus is that no matter how large the volume of current may be, only a small fraction is required to operate the device, and this only for an infinitesimal period of time, the device in opening disconnecting both the safety apparatus and the interior wiring from the outside source of danger. Another advantage is in the fact that the device provides special facilities for rapidly testing the local system for grounds, without the use of other apparatus. During the past few years many fires have originated from high potential currents accidentally traversing secondary systems and breaking down the insulating joints which intersected the junction between fixtures and gas pipes. From the manner in which first-class electric light wiring is installed at the present day, it would seem impossible for a current at a potential of say two thousand volts, to cause a rupture between secondary wiring and ground, and the writer's experience leads him to the conclusion

*From a paper read before the Canadian Electrical Association.

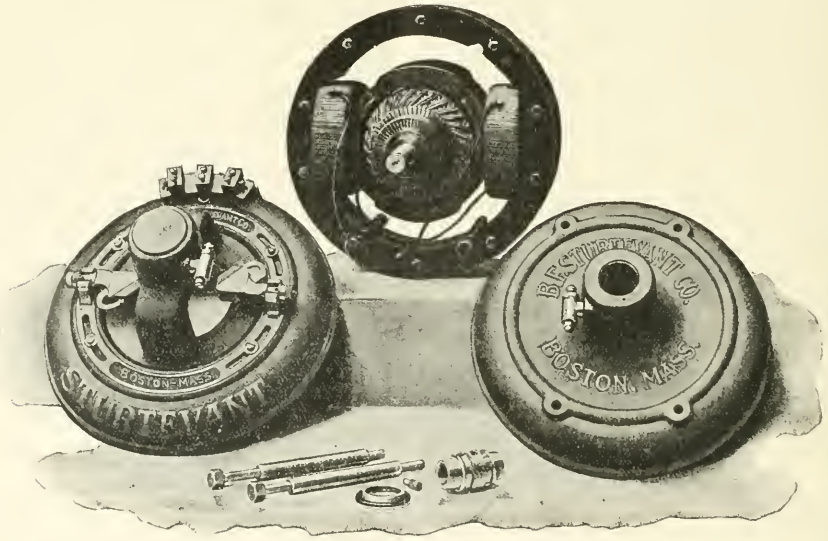
that if the so-called insulating joints properly performed their function, fires from this cause would be extremely rare.

If on the other hand low potential systems are so arranged that there is no chance for high potential currents to rupture to ground, there remains the danger of some person receiving a fatal shock while handling the apparatus. In view of these facts, it would seem advisable to equip all low potential systems, which are exposed to the contingencies herein mentioned, with an automatic device that in time of need will operate effectively.

A NEW TYPE OF ELECTRIC PROPELLER VENTILATING FAN.

Since the B. F. Sturtevant Co., of Boston, Mass., has entered extensively upon the manufacture of electric motors and generating sets, it has been carefully studying the problem of the manufacture of a compact, efficient and convenient type of electric ventilating fan. Exhaustive tests were made with different types of fan wheels. The result is made clear by the accompanying engravings, showing views of one of its electric ventilating fans, which have just been put upon the market. The fan wheel has eight blades rigidly attached to a spider at the

centre, and held in place by a hoop at the periphery, at an angle of approximately 30 deg. The angle is increased in such a manner that as the centre is approached the theoretical velocity of the air remains practically constant. In other words the delivery edge is helical, and the air is picked up on the inlet edge of the blades at low velocity. When well under the influence of the blades, it is accelerated to its maximum velocity with the least amount of slip. The result is an extremely efficient wheel. The motor likewise has been the result of very careful study in the attempt to provide a light machine, entirely enclosed, and at the same time to avoid the excessive temperature which is incident to the operation of most enclosed motors. The result is a machine capable of continuous operation for ten hours, with a maximum temperature rise of not exceeding 30 deg. F. A practical efficiency of over 80 per cent is obtained even with the small sized motors, and an excess load of 75 per cent. above the rated capacity may be carried without sparking, and without changing of brushes. This feature, combined with the small temperature rise, allows of carrying temporary overloads with impunity. The bearings are self-oiling and self-aligning, and are fitted with phosphor-bronze sleeves, which are



removable from the outer ends of the boxes. The wheel is partially enclosed in a conoidal inlet ring, which decreases the frictional resistance to the entering air, and furnishes at the same time a rigid support for the motor, to which it is attached by the tripod hanger. These fans are built in sizes from 18 inches to 120 inches, with motors designed for either medium or maximum speed, and to run at any ordinary direct current voltage. A speed controller is always provided by means of which the fan can be efficiently operated at different speeds.

THE PRACTICAL MAN.

To find the proportions of a toothed wheel.—Pitch of teeth = circumference of pitch circle ÷ number of teeth; number of teeth = circumference of pitch circle ÷ pitch of teeth; circumference of pitch circle = pitch of teeth x number of teeth.

To find the diametral or Manchester pitch.—Divide the number of teeth in wheel by the diameter of pitch circle in inches.

To find the angular velocity of a wheel.—(1) Multiply the circumference of wheel by number of revolutions it makes per minute and divide by 60 = linear velocity in feet per second; divide linear velocity by radius of wheel = angular velocity. (2) Multiply number of revolutions per minute of wheel, 360°, and divide by 60 = angle described by wheel in one second; divide this angle by 57.296 = angular velocity.

To find revolutions per minute of a driving or following wheel or disc.—Revolutions of driver x revolutions of follower x diameter of follower ÷ diameter of driver; revolutions of follower = revolutions of driver x diameter of driver ÷ diameter of follower. Note.—The number of teeth may be taken instead of diameter of wheel.

To find the diameter of a driving wheel or following wheel

or disc.—Diameter of driver = revolutions per minute of follower x diameter of follower ÷ revolutions per minute of driver; diameter of follower = revolutions per minute of driver x diameter of driver ÷ revolutions per minute of follower.

To find the velocity ratio in a train of wheels.—Multiply together the number of teeth in each driving wheel, multiply together the number of teeth in each follower; the first product will be the number of revolutions the first driver makes, while the second product is equal to the number of revolutions the last follower makes in the same time.—From Rules and Definitions by Wallace Bently, A.I.Mech.E.

LONG BURNING ENCLOSED ARC LAMPS.*

BY WM. A. TURBAYNE, HAMILTON.

The major factor of expense coupled with the operation and maintenance of arc lamps arose from renewing the carbons, which, in the sizes adopted in practice, had a life of some seven or eight hours only. As the all-night lighting of streets demanded that lamps should be capable of giving an uninterrupted service of from twelve to fourteen hours' burning, various means were devised whereby this period could be covered by a single trimming of carbons. Innumerable types of lamps were designed with this end in view, but there remained to be adopted as standards the double carbon lamp, which burned two successive pairs of eight hour carbons and, as an alternative, the single carbon lamp fitted with circular or elliptical carbons of sufficient cross section to insure a life of fourteen or sixteen hours. Aside from the matter of trimming, however, the carbons themselves were a source of heavy expense, and early endeavors were made to perfect some means whereby their life could be materially prolonged without at the same time incurring a sacrifice of the light. It was clearly understood that the rapid wasting away of the carbons was caused mainly by their combustion in the open air, and it naturally occurred that if the arc could be maintained in a transparent chamber, from which the oxygen of the air had been excluded, that this combustion would cease and that then the only waste would be that due to vaporization. Experiments along these lines were conducted and the results would undoubtedly have been encouraging had it not been chiefly for the fact that, in burning in an enclosing chamber, such a deposit soon accumulated on its inner surface as to seriously obscure the light and thus render the arrangement unpractical and, therefore, as these attempts to increase carbon life proved futile, fourteen or sixteen hours per trim was, until very recently, accepted as the burning period of an arc lamp. The great demand within the last eight or ten years for interior arc lamps operating from incandescent lighting circuits was met by a marked improvement in carbon manufacture, until finally a practically pure article was obtainable, the advent of which made possible the maintenance of an arc in an enclosing chamber and allowed of the development of the long burning lamp as we have it to-day in which a carbon in size equal to the eight-hour carbons of open arc lamps has a life of one hundred and fifty hours or more.

This longevity is effected by preventing combustion by a removal of the oxygen from the space immediately surrounding the arc, the oxygen not being literally removed by exhaustion, but rather by a process of chemical conversion wrought by the action of the arc itself. The carbons are surrounded by a glass globe of small area, closed at the base and only sufficiently open at the top to allow of a free passage of the upper carbon. On the formation of an arc the air contained within this globe is heated and rarified, the surplus finding an outlet through the upper opening; the remaining oxygen is reduced by combustion with the carbon to carbon monoxide (C.O.), a gas which is somewhat lighter than air, having a specific gravity of .969, and although combustible will not support combustion. This, together with the nitrogen which is liberated, completely fills the chamber and prevents further combustion of the carbon, although a small amount of air diffuses through the upper opening—a condition essential to satisfactory operation, as otherwise the vaporized carbon would condense and appear as a sooty deposit on the inner surface of the globe, while as it is, the oxygen of the entering air unites with this vapor and forms a gas. A slight deposit of silicon accumulates, which, however, does not seriously absorb the light, and which may be readily wiped off during trimming.

As a result of the absence of oxygen in the enclosing globe the ends of the carbons do not become tapered by burning but remain flat and blunt, and the device could not be adapted successfully to the existing lamps in use, which maintain a potential difference of some 45 volts across the arc, as, in the small separation of one-eighth inch or under consequent upon this voltage, too much of the light would be intercepted by the lower carbon. It was therefore imperative, in order to obtain proper distribution, that the carbons be more widely separated, and it was found that in the enclosure an arc of approximately ⅜-inch in length could be maintained with an E.M.F. of some 75 or 80 volts. Meanwhile it is necessary that the current employed should not exceed 6½ or 7 amperes, for obvious reasons associated with the cleanly burning of these lamps for long periods, and in order further that the watts expended may correspond with those expended in an open arc lamp of like rating. While a so-called 2,000 c.p. lamp of the latter type operates with a current of 10 amperes at an E.M.F. of 45 volts or 450 watts, an enclosed lamp of like rating may operate at 6.5 amperes and 70 volts, or at 5.5 amperes and 82 volts, the higher E.M.F. and reduced current resulting within certain limits in better operation. Enclosed arc lamps in general require special features in the feed mechanism, although the governing principles are identical with those obtaining in the open lamps. As it is necessary to separate the carbons from ⅜ or ½ inch it is usual to have the magnets act directly on the upper carbon without the intervention of levers, and this calls for a long range magnet of considerable power. In order also to obtain good regulation it is desirable that the moving armature be of considerable weight, as compared with the weight of the carbon to be lifted, as therefore decrease in weight of the carbon is not accompanied by an appreciable lengthening of the arc. Enclosed lamps will operate efficiently in series on direct constant current circuits employing currents not greater than 6.8 amperes, and on alternating current circuits in conjunction with constant current transformers. In these instances the lamps must be of the differential or shunt feed type, and must be further provided with short-circuiting cut-outs such as are found in the well-known open series lamps. A similar type of lamp is required for operating in series multiple on street railway and power circuits, but in place of the short-circuiting cut-out a device for shunting a resistance, equalling that of the arc, across the terminals is used in order that if one or more lamps cut-out or proved defective the current traversing the remainder would not rise. It is necessary also that a steadying resistance be placed in series with each group of such lamps.

Enclosed lamps for operating in parallel on direct and alternating current incandescent lighting circuits require a very simple feed mechanism and contain neither shunt magnets nor cut-outs. For adjusting the carbon a single magnet only is required connected in series with the arc. Such a magnet responds to variations in the current strength and tends to maintain this factor constant irrespective of variation in terminal voltage, but as this latter is a constant factor the magnet therefore in keeping the current factor constant must likewise keep the arc resistance and length constant also. A retarding device such as a dash pot is required in these lamps to allow of a gradual separation of the carbons, alternating lamps especially demanding a comparatively slow separation. As direct current lamps usually operate on circuits of 110 volts it is necessary to interpose a resistance in order to reduce this to about 80 volts as required across the arc, and, while this resistance wastes energy, yet it is necessary to the successful operation of the lamps. The alternating lamps are more fortunate in this respect inasmuch as a reactance coil may be placed in series with the arc which will reduce the voltage to that required across the arc with but little waste of energy. They may also be operated direct from transformers delivering the necessary arc voltage, or from economy coils, or auto-converters.

A type of lamp which represents simplicity in the extreme is that in which the separation and feeding of the carbon is effected by the expansion and contraction of a strip of metal interposed in the path of the current. Such a device, while not satisfactory when used in conjunction with open arc lamps, appears to be excellently adapted to parallel burning enclosed lamps, in which the arc is protected from draughts of air, and which feeds only

*From a paper read before the Canadian Electrical Association.

at long intervals. For this particular purpose, as compared with electro-magnetic feeds, the advantages all appear to be with the thermal feed. Such lamps strike their arc quietly and slowly without being necessarily retarded in their action by dashpots, their feed is positive, and slight frictions in the moving parts introduce no noticeable error; they may be operated at will on direct currents, or on alternating currents of either of the standard frequencies. On alternating currents the power factor of a load of these lamps would be high as compared with a load of lamps having large magnet coils and cores, and in the matter of maintenance there appears to be nothing about such a lamp to suggest repairs, although the replacing of an occasional regulating strip would be much cheaper than the renewing of magnets.

Aside from the economies of enclosed lamps resulting from the increased life of the carbons they possess other advantages peculiar to themselves. As a result of the absolute enclosure they burn quietly, being free from hissing or flaming even though not accurately adjusted, and, as it is impossible for sparks to make their exit, all possible fire risk is eliminated, a feature which meets with the unanimous endorsation of the boards of Fire Underwriters generally. By virtue of the long arc which is maintained more perfect distribution of the light over large areas is obtained than is possible with open arc lamps Direct current lamps of the latter type exert their greatest illuminating effect at an angle of about 45 degrees from the vertical so that a very intense light is noticeable within a radius slightly exceeding the height of the lamps from the ground, while beyond this the illumination rapidly falls away. Enclosed lamps on the other hand spread their rays more horizontally, their angle of maximum intensity being about 75 degrees, and as a result the light is more regularly diffused over a large area and does not assume the form of concentric zones of rapidly diminishing intensity. The economy in maintenance however, affords the most striking example of the advantages of enclosed lamps over the open and the gain will be clearly noted by a comparison of the two systems. As an example we may compare the maintenance costs of 450 watt open and enclosed alternating current lamps operating 10 hours per day per year of 365 days, assuming for the former a life of 14 hours per trim of carbons costing $36 per 1,000, while for the latter a life of 80 hours per trim of carbons costing $30 per 1,000. In this comparison the matter of interest and depreciation allowance may be dismissed on the assumption that it will be similar in each case and thus there remains to be calculated the cost of carbons and trimming.

As the open lamp requires two new carbons per trim it will in a year therefore, on the above basis of 10-hour runs per day, require some 261 pairs of carbons, costing $18.80; on the other hand the enclosed lamp requires but one new carbon per trim and in a year will consume but 46 carbons, costing $1.38, so that an annual saving of $17.42 per lamp is effected by the use of the enclosed lamps. The cost of trimming will depend largely upon local conditions, but we may assume that one man at $2 per day can trim one hundred open lamps, or one-half as many enclosed lamps, which will make the cost per trim, therefore, 2 cents and 4 cents respectively. On the 10-hour basis the trimming, therefore, will cost approximately $5.62 per open lamp per year, as against $1.84 per enclosed lamp per year, resulting in a further annual saving in favor of the enclosed lamp of $3.78, making the total saving $21.17. With direct current lamps the saving will be in like ratio, allowances for differences in the life and cost of carbons being necessarily taken into consideration, but whether direct or alternating the advantages of the enclosed lamp are so apparent that before a great period elapses not only will they largely supplant the open arcs, but they will further enter the arena in competition with large incandescent lamps and regenerative gas lamps.

STEAM POWER FOR AUTOMOBILES.

For some years Sir David Salomons and other experimenters and engineers in Britain have been vaunting the praises of steam as a motive power for autocars, arguing for it as the ideal power on account of its expansiveness or range, and hence being superior to the gasolene engines whose limits are but too well known, and resembling electricity minus the difficulty of recharging batteries. The Serpollet boiler gave Sir David and his friend good ground for argument, and as a matter of fact steam is being pushed to the front in Britain, especially for heavy traction. The Americans have done much better with steam automobiles than either British or French inventors—the latter having given chief attention to gasolene, or "upetrol," as it is called. Some rather sudden and surprising developments in steam autocars have been made in New England. It is to be noted that the Western and Middle States of the Union have as yet produced no steam autocar. The reason stated by experts is that nowhere in the United States except in New England can the extremely fine work be had that is required in steam vehicles. Every engineer will understand that a 4-wheel two-passenger carriage, whose total weight empty does not exceed 400 lbs., the boiler shell being only 14 inches diameter by 13 inches high, and yet containing 306 tubes, requires exact adjustment and minute mechanism that would drive the ordinary machine shop foreman crazy. Yet the Stanley brothers had no difficulty in getting such work done in a rush, so that their first carriage was completed within six months. New England now boasts three prominent steam carriage makers—Whitney of East Boston, Stanley Brothers, the famous dry-plate makers of Newton, Mass., and the Overman Wheel Co. of Chicopee Falls, Mass.

At the motor vehicle contest in Boston in November last, the performance of the steam carriages astonished the crowd of 2,000 persons, for steam power done up in such compact form was decidedly novel. On a 3-lap cycle track the Whitney wagon, weighing 1,000 lbs., made a 2-mile run in 5.40 2-5, while the Stanley wagon, weighing 400 lbs., finished the mile in 2.11. Whitney says he has often made a straight-away mile inside of 2 minutes.

The hill climbing contest gave the hardest test. A plank track 85 feet long was laid level for the first 10 feet, and the balance in sections of 10 feet, each section raised 5 degrees higher than the preceding, the final angle being 35 degrees. This made a constantly increasing up-hill angle of track, which is

Stanley Steam Carriage.

vastly difficult. Some seemingly powerful cycle riders tried it with a flying start, but could not go much above half way up Whitney with 125 lbs. of steam ran up the grade beyond his brake control, and had to be caught by men standing on the incline, and steadied down to where his carriage could take care of itself Stanley took the hill, running up to the top, and bumping the cross bar at the end, from a standing start at the bottom of the incline, no headway run on the level being made. Stanley had probably 150 lbs. boiler pressure for this hill effort It looked as though Stanley was going to come down with a rush, but after some hurried scrambling the wagon was seen to be under control. The Stanley engines were not made to reverse, but the reversing feature has been added since this test.

The following particulars in regard to the power and gear of the Stanley steam wagon, given by Hugh Dolmar in The Cycle Age, will be of interest to steam engineers: "Boiler shell

copper, 14 inch diameter by 13 inch high; No. 20 B. & S. sheet metal gauge in thickness; 300 tubes, copper, ½-inch diameter, 13 inches long, No. 20 B. & S.; fuel, gasolene; cylinders, a pair of simple engines, 2¹⁄₄-inch bore by 3¹⁄₄-inch stroke, plain eccentric valve motion, plain slide valves, no link, fixed cut-off at about 9 to stroke. The speed reduction from the engine shaft to the compensating gear box is 2.2 to 7.12 tooth sprocket on engine shaft, and Baldwin separable chain to a 33 tooth sprocket on the gear box. Driving wheels, 28 inch diameter, with suspension, laminated wood rims and 2-inch Hartford single tube tires. Running a mile in 2.11, the engines made 720 by 2¹⁄₂, or 1,800 revolutions, and the number of exhaust was 7,200. The engines made a little under 837 turns per minute. The boiler pressure was probably about 140 lbs., and as all the connections are very direct and short, it seems that the mean effective pressure on the pistons should be little short of 80 lbs. However, the combined piston area is 9.8 square inches, and the piston travel was 487 feet per minute, going something like 11 h.p. nominal. This seems incredible for a boiler of the dimensions given, and it seems therefore probable that the mean effective pressure must have been below the 80 lbs. assumed."

In speaking of the conduct of the Stanley wagon during the exhibition mile run, Mr. Dolnar states that there was a perfect absence of odor, ease and celerity of movement, and almost total silence. At Stanley's top speed the connecting rods and cranks were invisible, and the noise of the exhaust was an agreeable hum, almost a musical note, there being 3,348 puffs per minute. The exhaust steam spread out in a thin gray veil, and extended about six feet in rear of the wagon. Stanley and Whitney had practically the same boiler, and the only practical difference between them was that Stanley had a perfect burner under his boiler, while Whitney's was by no means so good.

The Victor Automobile—the name of the steam carriage just put on the market by the Overman Wheel Company—is introduced as marking a new era in the use of steam, "pre-eminently the power to use on automobiles," The makers claim they "have solved the problems which heretofore prevented the use of steam in the hands of the general public. With a Victor Automobile," they say, "it is possible to go for 25 miles and do absolutely nothing except to put the power on by opening the throttle and to steer." The height of water in the boiler and the pressure on the fuel tank are maintained automatically, and guaranteed not to vary beyond an inch of water or a pound of pressure. The wagon to seat two persons has 4 h.p., and is geared according to the hill-climbing or speeding necessities of the purchaser.

A curious feature of the development of the steam carriage in the United States is that the Stanley Brothers are neither of them engineers, and neither of them is to-day familiar with the ordinary details of steam engine construction; yet they have produced what Mr. Dolnar—an engineer of forty years' experience—regards as the closest approach to a practicable mechanically-propelled road wagon yet shown. They are men of unique personality, accepting nothing as authoritative, except the result of their own independent investigation and researches, and are utterly scornful of all practice and precedent. Whitney had built steam wagons before them, but they did not adopt Whitney's boiler construction, but originated an entirely new form of boiler shell, which makes the tube expansion and shell expansion always the same, and hence makes such a thing as a leaky tube unknown in their boilers. They also originated a gasolene burner for firing this boiler, which uses no forced draught or air pressure, and produces a silent fire without any of that roaring which had hitherto marked all oil-burning steam generators of rapid action.

There is just one bit of data that is lacking in the various accounts of the exploits of steam wagons which we have read, that is, the clogging of the tubes with lime deposit. If "scale" proves such a detriment to ordinary steam boilers, what may be expected of a multitude of minute tubes when limestone water is taken from the wayside pump, or dipped from the side-road ditch? How long would a traveler be safe from explosion if his runs should be made in a locality such as Guelph or Limehouse?

Horseless Vehicle Parade at Columbia College, New York.

THE PROPER EFFICIENCY OF INCANDESCENT LAMPS FOR CENTRAL STATIONS, INCLUDING A DESCRIPTION OF THE NERNST LAMP.*

BY E. E. CARY, ST. CATHARINES.

Few questions in the field of electric lighting are of greater importance to central station managers than that of the efficiency of incandescent lamps, and few questions seem so thoroughly misunderstood, and yet the fault is not entirely with the central station. In the first place, only the larger companies will invest in the necessary apparatus, and surprisingly few of these will purchase enough apparatus to determine the efficiency of their lamps. The initial outlay, including photometers and instruments, will more than pay for itself in the first year. In the absence of the proper outfit, the managers have to depend upon the statements of manufacturers or more often upon those of their representatives, and what is the result? Dissatisfaction. One maker will supply lamps guaranteeing them to be of a stated efficiency, and these lamps will give satisfaction. Should the next order be placed with another company and the same efficiency guaranteed, chances are strongly in favor of the second consignment not giving satisfaction, assuming the specifications call for efficient lamps. Both lots of lamps may consume the same current at the stated voltage and in reality be intrinsically equal, yet one will be thought well of and the other condemned. A situation such as this, upon the face of it, seems incredible, yet such is the daily experience of every lamp manufacturer until by long and often costly experience he becomes thoroughly acquainted with the actual state of affairs upon the lines of all his customers.

For many years generators, and later transformers, have been rated in light capacity upon the basis of fifty watt lamps. It has been unfortunate that 3.1 watt lamps have become such a household term, as their use has often proven very costly to companies before experience made them alter first ideas. Everyone will probably agree that it is desirable to use the most efficient lamps possible, consistent with fair life where current

*A Paper read before the Canadian Electrical Association.

is supplied upon the meter basis. Two questions immediately arise; what should be considered fair life, and at what efficiency under conditions existing upon the lines can this life be most economically obtained. Every lamp maker, however worthy of the name, has on record the results of many tests showing the average life to be expected of lamps of different efficiencies when operated at normal or at voltages other than normal. Below in table 1 will be found the efficiency and average life of lamps at various voltages. Though these results are in one sense approximate only, yet they are the average results of many tests. Before discussing the table, it is well to state that the efficiency of an incandescent lamp is generally given in watts per candle. A lamp radiating sixteen candles when operating at fifty volts, and one ampere of current, consumes fifty watts, and has therefore an efficiency of 3.1 watt per candle. When lamps are tested for efficiency, one grievous error is generally made. The voltage is taken carefully as labelled on the lamp instead of being taken at the point of the lines where the lamp will be used. For example any lamp, whatever its normal efficiency may be, can, and often is operated at a much higher efficiency. For instance a four watt lamp is often burned at three watts, and a three and a half watt often burns at two and a half watts. This is simply to show that when a manager talks of using more efficient lamps, he may be operating at that very time, lamps at a higher efficiency than he contemplates using.

If a station is using 3.5 watt lamps and had absolutely steady voltage, an average life of 900 hours could be expected. If the voltage, however, is 2 per cent. high, this life is reduced to 700 hours, and the efficiency increased to 3.27 watts. If, however, the voltage is 4 per cent. high the life is reduced to 550 hours, and the efficiency increased to 3.05 watts. Though the candle power is increased, the total watts consumed is not proportional and the station suffers doubly in consequence. Four per cent. increase in voltage of a sixteen candle power lamp increases the light emitted about 20 per cent. This table will probably impress on central station managers how vitally important it is to know the voltage at which their lamps are operating upon different portions of their lines. Unless the regulation throughout the system is unusually uniform, it is most profitable to have the entire system divided into sections or zones, and order lamps of different efficiencies adapted to give the life settled upon as desirable. If the fluctuations are comparatively the same in the different zones, then the same efficiency can be used, only the lamps should vary in voltage, the voltage to be used to be the same in each zone. The manager immediately states that this causes too much confusion, etc., yet it is good business, and is a no more confusing problem than many others in manufacturing. When a method like this is carried out, very black lamps would disappear, average life be greatly increased and customers would be much better pleased. Take a customer upon your lines where the voltage is 4 to 6 per cent. high, not to speak of 20 per cent. as is often found, and when you replace burned out lamps what is the result; the new lamps may emit from twenty to thirty-two candles and the old lamps eight to ten. Naturally the customer complains that the old lamps are worthless, and to keep peace, you replace these also and he starts with practically all new lamps, the same trouble to be gone through with later on. In the meantime you are apt to write the manufacturer that his lamps are blackening badly and return these specimens as fair samples. Troubles arising from cause similar to this have forced manufacturers oftentimes, who cannot or will not investigate the trouble, to send out their lamps uniformly of a higher voltage than is marked on the labels. This is one sense self protection, which the manufacturer is forced to do if he wishes to retain the trade which is often at such a distance that he cannot afford to investigate personally.

Most lamps imported from the United States to-day are much higher in voltage than indicated on the label. Yet the central station, if it has not due regard for the light emitted, will be pleased with the lamps, as they may last almost indefinitely. The most welcome information a manufacturer can receive is to the effect that a central station does not wish a lamp to last forever, so to speak. Consider for a moment how small the expense of the renewal item is under normal conditions. Assuming only 600 hours average life at the low average meter rate, 6-10 cents per lamp hour, the income is 3.60. Good lamps can be purchased for 20c. each or less than 6 per cent. of the income. When lights are furnished upon the flat rate basis, and the renewals are paid for by the consumer, highly efficient lamps are not desirable.

When central stations will determine intelligently the proper efficiencies of lamps which they should use, and take means to hold manufacturers to their specifications, then their lamp renewal account will considerably decrease and the legitimate lamp maker prosper proportionately. Below is given another table of current in amperes taken by lamps at various voltages and candle powers at different efficiencies, which may be found useful for reference:

EFFICIENCY AND AVERAGE LIFE OF LAMPS AT VARIOUS VOLTAGES.

Before describing the Nernst lamp I will say in reference to 220 volt lamps that great progress has been made in their manfacture during the past year or two, but that little further is necessary in making them more efficient before they will be on a par with 110 volt lamps. In addition to this, plants must be installed calling for a range of 220 to 240 volts before the cost of the lamps can be brought to its proper level by the manufacturer.

During the past year vague rumors have occasionally been

wafted across the water of the discovery of a new light, although details of the discovery were entirely lacking until Mr. Swinburne delivered his now famous lecture before the Society of Arts in London, February 8th. I will quote from this lecture a few descriptive remarks and then give some criticisms of the lamp from other sources. Mr. Swinburne in speaking of Nernst's discovery says: "Nernst's, like most great inventions, is exceedingly simple as soon as it is understood. The efficiency of an incandescent body, as far as radiation goes, depends simply on temperature of the filament only, providing there is no loss by convection. The carbon will not stand a sufficiently high temperature. Nernst therefore chose a material that would stand higher temperature than carbon, and his material has the incidental advantage, that its specific resistance is so high, that strong rods can be used for high pressure instead of thin filaments. Nernst takes highly refractory oxides as his material. It does not seem promising, because such oxides are notoriously good insulators. But such insulators are electrolytes when hot; Nernst therefore, heats the rod to make them conduct, and then heats them electrically, preserving a temperature which is within the limits that the material can bear without softening. * * * The material is worked up into little white rods. Each rod is mounted on two platinum wires, a little paste made of refractory oxides being applied to the joints. The little rod with its two wires, is then mounted in holder which fits ordinary electric light fittings. As the rods fall in resistance as the temperature increases, after the manner of electrolytes, an increase of current produces a decrease of resistance. This tends to give some instability in running in parallel on supply circuits. This instability is corrected, as in an arc lamp which has analogous properties due to a different cause by a series resistance. The Nernst rod has therefore a resistance in series. This is made up of exceedingly fine wire, and for ordinary circuits amounts to 10 or 12 per cent. of the whole resistance of the lamp. The consumption, including the resistance is 1.5 watts per candle for large lamps, and 1.6 for small lights of low pressures. In small or low pressure lamps the loss of heat at the ends is larger in proportion. Such a lamp as I have described will not light up of itself, for the rod is an insulator when cold. The simplest way to start it is to warm it with a match, or better with a small spirit lamp. Such a lamp as this is not only very cheap as regards first cost, but economical in running. The life of rods, running at an efficiency of two-thirds of a candle per watt, including the resistance, is already more than 500 hours in good specimens. If the Nernst lamp advances as much in the first years of its existence as the carbon lamp did between 1880 and 1882, it will soon be made so well that the rods will last a lifetime. When the rod is worn out, a new rod with its little mounts is all that is replaced. The whole lamp is not thrown away at all. The small lamps and the lamps of medium size are in practice started by a heating resistance. This is arranged close to the rod, and in shunt to it. As soon as the rod is hot enough to conduct, its current works a tiny cut-out in the resistance circuit. In large lamps the heating system is a little more elaborate, as the resistance arrangement is arranged as a sort of hood which covers the rod. As soon as the rod conducts, not only is the resistance circuit broken, but the electro-magnet lifts the little hood clear off the rod. In all these forms, the rod and its mounting are replaceable without interfering with the rest of the lamp."

The above extracts give a very clear idea of the Nernst lamp, as first described to the public by those interested in promoting a large company for its exploitation. There are however serious practical difficulties involved in the practical operation of these lamps at the present time. Assuming however for the sake of argument that the Nernst lamps can be operated successfully in practice, the relative cost of this operation compared to arc and incandescent lamps is what chiefly interests the central station manager. The English Electrical Review recently published an article by John I. Hall upon "The Nernst Lamp vs. The Arc and Incandescence Lamps." I quote for your information a part of this article, giving comparisons in cost between the Nernst and arc lamps. These are the only figures that have been recently published. After speaking of various methods of lighting, Mr. Hall writes: "But at present the position of the various illuminants may be summed up as follows. 1. The Welsbach system is an advance over the ordinary method of lighting by gas 2. The enclosed arc lamp is an advance over the open arc. 3. The Nernst system is an advance in incandescent lighting. The electric lamps are placed in the order they will occupy in regard to cost of maintenance, for as the Nernst lamp supersedes the enclosed carbon lamp, so does the arc lamp supersede the Nernst lamp." J. Swinburne, in the prospectus of the Nernst Electric Light, Limited, states that: "It will, I believe, oust the arc lamp in nearly all cases." On examination it will be found that it will not oust one arc lamp at present in use, as the following particulars will show:

The Nernst lamp is said to give 1 c.p. for an expenditure of 1.5 watts. The arc lamp (2,000 n.c.p.) absorbs 500 watts and actually gives 1,200 c.p. The Nernst lamp to give 1,200 c.p., will require an expenditure of 1,800 watts, or 3.6 times more energy than the arc lamp; 1,800 watts = 1.2 kilowatts per hour, which will cost to the consumer 3.6d. per k.w. per hour. The arc lamp absorbs 0.5 k.w. per hour, and this at 3d. per unit equals 1.5d. These figures are for public lighting; for private consumers the cost is, of course, increased. Allow a liberal amount for carbons, trimming and cleaning, etc., say, 0.5d. per hour, then there is 1.5 + 0.5 = 2d. per hour as the cost of the arc lamp against 3.6d. as the cost of the Nernst lamp. The figures given above are for the open arc lamp, but for the enclosed arc lamp the cost would be about 1.6d. against 3.6d. for the Nernst lamp. In other words, instead of our corporations running their street arc lamps for, say £18 per annum per lamp, they will, by adopting the Nernst lamp, run them at £64, or spend £46 more per lamp.

It will therefore be considerable time before the municipal electrical engineer is found who will be ready and willing to come forward and suggest the ousting of the arc by the Nernst lamp. The Nernst Electric Light, Limited, prospectus further states that "there is no difficulty in running in parallel on 1,000-volt circuits without transformers." It will be of some interest to the electric light engineers to find the 1,000-volt circuits without transformers amongst the electric lighting stations. However, the merits of the 1,000-volt lamps can be considered as against the arc lamps. Suppose the advantages of the Nernst lamps are considered running in parallel on 1,000-volt mains. Is there any economy in conductors to be secured under these circumstances? Take a section of, say, 20 arc lamps, with transformers, running in parallel and controlled from a substation. The current required will be

$$\frac{20 \times 500 \text{ watts}}{2{,}000 \text{ volts}} = 5 \text{ amperes primary current.}$$

For 20 Nernst lamps the current will be

$$\frac{20 \times 1{,}800}{1{,}000} = 36 \text{ amperes primary current.}$$

Thus it will be seen that, taking the most favorable conditions set down by the prospectus of the company for the Nernst lamp to compete with the arc lamp, a cable of seven (7) times the sectional area will be required, in addition to the transformer, for them to run on existing installations where the E.M.F. is 2,000 volts. The cost of the lamp cases and posts now remains to be considered. It may be taken that the lamp-posts will cost about the same in both cases. The arc lamp complete, with hood and globe, costs, say, £6, and the Nernst lamp £1. This appears to be a fair price, allowing for promotion anticipations without actual figures as to cost. The first cost, and maintenance for 12 months, may now be considered, voltage 2,000 lamps in parallel:

Arc lamp and transformer, say	£12
Say cost of cables	3
Maintenance for twelve months	18
Total cost	£33
Nernst lamp and part cost of transformer situate in sub-chamber (voltage 2,000 to 1,000)	£ 3
Cost of cables	21
Maintenance for twelve months	64
Total cost	£88

There are other considerations of cost, such as conduits, depreciation and interest on capital outlay, which the electrical engineer will observe are not in favor of the Nernst lamp, and so they are, in kindness, omitted. To summarize the foregoing

particulars, it is pretty plainly to be seen that the rosy and light-hearted view taken by the Nernst Company as to ousting the arc lamp will need some slight modification, especially on the score of first cost and economy. Unfortunately for the newcomer there are such things as cables to be taken into account and maintenance.

So, then, the manufacturers of open and enclosed arc lamps are not yet to put up the shutters, stop the machinery, and discharge the workmen; but it is not so pleasant an outlook to the carbon lamp manufacturer unless he commences to make the Nernst type of lamp (under license, of course) or improve the carbon lamp, as will appear later on. But there are other considerations to be taken into account where the advent of the Nernst lamp will be most beneficial, and where it will be appreciated, as we shall have for street lighting two illuminants to choose from, and where one is not applicable the other will be most serviceable. It may be considered that for lighting large areas such as squares, public markets, etc., and main streets and roads, the arc lamp will not be superseded, but for the lighting of narrow streets, public halls, etc., the Nernst lamp will be a most valuable acquisition, on account of the increased economy in running. In all the circumstances it must be considered that the lamp is automatic in its action, as the match-assisted lamp is out of question in 1899, excepting, of course, to the promoters. The engineer and manager of one of the most successful gas works in the country said to me, when discussing the merits of the Nernst lamp: "Why, you will be going back to the old barbarous times of gas lighting if you use a match to light your incandescent lamp, and all the advantages of the enclosed filament lamp will be dispensed with."

TRANSFORMER ECONOMY.*

F. H. LEONARD, JR., MONTREAL.

(Continued from last issue).

Central station practice has not yet settled down to uniform methods of installation, but the trend now seems to be in the direction of larger transformers with secondary networks preferably on the thin wire system. The general introduction of meter basis of charge, making it possible to safely connect double the rated transformer capacity in lamps to the secondary network—whereas with the older systems, providing a separate transformer for each connection, it was necessary to provide transformer capacity equal to the lamps connected. With separate transformers of small sizes, necessary for individual supply, the aggregate core losses become a serious drain upon the central station. We have frequently seen banks of small transformers serving a single customer or group of customers, this condition being brought about by the gradual growth of demand for light exceeding the capacity of the original transformer installed, a further growth exceeding the capacity of the second, and so on. In such cases the substitution of a single large transformer of modern design, displacing the small ones, would save its price in less than a year, if credited at the usual selling price, with the amount of current saved. Don't put a modern transformer of good regulation into a group of antiquated transformers of poor regulation; if you do you will lose your new transformer, which is likely to be unjustly condemned for trying to improve the regulation of its bad associates. Placed in such company, the new transformer tries to maintain the good regulation for which it was designed, while the lazy, old slurks, with which it is connected, steeped in the vice of bad regulation, throw their entire load on to the new comer, which good naturedly carries it all till it can no longer stand the strain, and literally roasts out and breaks down under the load.

In most of the smaller stations, and in many of the larger ones, money can be saved by remodeling the system of distribution, and at the same time improving the service by laying out a net work of secondary mains, starting first in the business portion of the town, with the installation of a few large transformers, reserving the small transformers, which these replace if they are modern and worth keeping—for extensions in the more remote sections, where for the time the secondary network is impractical. It may occur in some cases the secondary network will be practical in several different sections, and these separate sections will, in most cases, gradually grow together, allowing taps to be made for new customers at intermediate points. In most cases, where prices are based on meter rates, such an arrangement can be installed at no greater first cost than the individual transformer system—the saving in cost of transformers, on account of their larger size and less total capacity required, paying for the copper mains. Such an arrangement always results in more satisfactory service to the consumers, at the same time greatly reducing the leakage current necessary to magnetize the transformers or supply the waste in core losses.

A few figures may serve to impress the idea more firmly in your minds. Let us take the case of a station having an average load, equivalent to 1,000 lights, most of which average four hours burning per night, and making due allowance for belting, dynamo, line, transformer and secondary wiring losses, we will allow that 10 lights are obtained per 1 h.p. at full load. In the first case we will suppose an individual transformer system is installed, using 10 10-light, 10 20-light, 10 30-light, 5 40-light, and 4 50-light transformers, even with modern transformers these would have an aggregate core loss of about 1,200 watts. If we substitute for this arrangement 6 150-light transformers, connected with a secondary main, retaining the 10 small transformers for isolated customers so scattered as to make it impractical to connect them to the secondary mains, our core losses will be reduced to 692 watts, or a saving of 448 watts for every hour the plant is run, which for twenty-four hours a day would amount to 3,920 k.w. hours per year, which at 10 cents per k.w. hour would be $392, or 6 per cent. on more than $6,500, a sufficient amount to more than pay for the change, if no consideration is made of the transformers left on hand, which would be superseded by the new arrangement. In the case just mentioned, we have assumed the original arrangement to be modern transformers. Had we assumed them to be old types, the saving would have been three or four times that shown, and would have allowed us to make a good or a better showing had we only charged 3c. per k.w. hour, which would be less than the cost of production in a station of 1,000 lights capacity. Some of our friends may argue that these losses cost them nothing, as they are running on water power, but we would like to remind them that the capacity in their generators, water wheels, or whatever prime movers they use, represent capital invested which add to the fixed charges their pro rata of interest and depreciation for which it makes no return, whereas, if the capacity used in overcoming these losses could be rented at the usual rates, a material difference in the capacity to pay dividends would be shown.

*Paper read before the Canadian Electrical Association.

CENTRAL STATION ACCOUNTING FROM A BUSINESS STANDPOINT.*

BY P. H. HART, MONTREAL.

The reasons why a standard system of accounting for central stations ought to be adopted are many and substantial. The individual owner of a small plant is as much interested in having accurate knowledge of the condition and details of his business and a determinate method of obtaining such condition and details, as the manager or directors of a large joint stock company. A proper system of accounting should show to the directors, manager, proprietor or other interested party (and for the sake of brevity I will hereafter refer to such parties as manager) besides the profits or losses of the business, the cost of producing what is sold, and should demonstrate this cost in such manner as to enable him to learn what the product costs in its various details, and particularly the costs separately of generation and distribution. These being determined and ascertained in the ordinary progress of business and due account being had of interest on investment and depreciation of plant, the manager can compare costs and determine where excesses arise, whether in the generation or distribution, and the reasons therefor. It should also show promptly and definitely the condition of affairs of a business at any and for given periods, which is a decided requisite and absolutely essential to sound business administration. It should be such as to enable the manager to determine the advisability of soliciting or catering for any particular line of business that may be offered or obtainable and

*A paper read before the Canadian Electrical Association.

indicate the most profitable, and be a guide, preventing indiscriminate investment in pole line construction, apparatus, etc., and show at all times the value of the investment for such purposes as insurance, arbitration, assessment, etc., etc. With such information created, compiled and formulated in the regular progress of the business, the manager will be enabled to consider intelligently operating costs and the advantages or disadvantages of further investment. I may here call your attention to some interesting information which appears in the 14th annual report of the Board of Gas and Electric Light Commissioners of Massachusetts, Public Document No. 35. This shows that out of 58 electric light companies operating in that State, with a total investment of over $17,000,000, five of the companies appear not to have earned expenses, and 32 have not earned sufficient to warrant the declaration of any dividend: thus very near 10 per cent. of the electric light companies operating in that State do not earn expenses, and 37-58, 63 per cent., are not earning sufficient to make a return to the investors on their capital. Many of them, no doubt, may have believed they were doing well until a rigid system of accounting had been applied. These commissioners are doing much to standardize the system of accounting in use by electric lighting companies in that State, and this statistical information is the direct result of a uniform method adopted by these commissioners in adjusting the statements submitted by the various companies. H. A. Foster, who investigated in detail 160 electric lighting stations of the United States, for the United States census, in a work based on the information gathered by him in the taking of this census and recently published, entitled "Central Station Bookkeeping," regrets the lack of system in accounting shown by the various electric lighting stations which came under his notice, and lays particular stress on the necessity of accurate accounting in central station work, for obvious reasons.

In addition to other reasons for and the advantages of a standard system of central station accounting, I might say that in the event of the question of municipal ownership or purchase arising the manager should have definite knowledge as to the cost of investment, cost of operating, etc., to compare with assumed cost of municipal operation. I will now present to you a system of accounting at present in use, having the objects above outlined in view, the results of which have been highly satisfactory, and in connection with it a system of records which form necessarily a part of a thorough accounting system. In the presentation I will indicate some of the various books and forms in use. Central station accounting from a business standpoint should proceed from and be based upon an order system, guiding, directing and allotting in advance the distribution of expenditure for investment, operation or maintenance and of revenue to the several distributions or sub-divisions of those general items that may be deemed desirable. And here I may say that such sub-divisions should be as numerous as the several details of a business, and when arranged for and determined upon beforehand, becomes, in practice, very easy of allotment or apportionment. A written order should be issued covering each and every transaction, indicating the character of the transaction and the accounting to which the expenditure incurred therefor is to be charged, or the revenue derived therefrom is to be credited. This to be determined and declared in the order before the expenditure is made or the revenue derived. Such system necessarily means that for every debiting entry to an account, something must be credited and all entries and accounts must result in a perfect balance, so that double entry bookkeeping is absolutely necessary to the practical working and comprehension of this system. The system referred to herein, and partially illustrated by various forms or blanks, can be readily put into operation by any company and practically at any time desired. Under the system described as at present carried out, the accounting is eventually grouped into what may be designated as general accounts, which are kept in a general ledger. All the other accounts, subordinate to these general accounts, and forming what may be designated as the working accounts, and which lead up to and are finally grouped into general accounts, are kept in other or subsidiary ledgers. This subdivision of books or ledgers is done in this instance simply as a matter of convenience, because the volume of business is large and necessarily requires to be attended to by a number of persons; but the principle involved would permit carrying all the accounts in one set of books if the volume of business were so small as to make that desirable. The general accounts consist of the assets and liabilities, and may be sub-divided in accordance with the wishes of the manager—as, for instance, the asset account of merchandise might, if desired, be sub-divided into fuel, line supplies, station supplies or wiring supplies, etc., such accounts representing materials on hand for use as required, either for any addition to construction or for operation or maintenance of plant. The asset account of plant and construction account may be subdivided into station construction, lines and poles, real estate, buildings, etc. The feature of the general accounts is practically no different from that of any other double entry bookkeeping system of accounts. The method in which this system may vary from ordinary methods of bookkeeping is principally in what may be known as the working accounts, and it is here that the formulation of the accounting and the determination to which account work under any given order shall be entered, arises. In the forms shown will be noticed the titles of sub-divisions of the working accounts representing expenditures. They show construction accounts, operating accounts and maintenance accounts subdivided into the various details, upon which it has seemed desirable to accumulate and record information. All orders issued involving expenditure recite thereon the account and sub-account to which the expenditures made thereunder are to be charged, and all returns of labor, material or expense incurred upon such order are reported, quoting the number of such order (all such orders being numbered serially). Expenditures which are continuous during the entire year, such as, for instance, labor and material and expenses for the operation and maintenance of the station, or labor and material required for the trimming and inspection of arc lamps and lines, may be dealt with by orders covering the entire year or parts thereof, say monthly, the latter being preferable. Monthly orders for work of this character are preferable to yearly orders, because as soon as the expenditure authorized under an order has been completed, such order is turned in to the office or bookkeeper, marked as completed, and thereafter no expenditure can be made chargeable to that order.

It will be observed that the purpose sought to be accomplished by these orders is the localizing and sub-dividing of the expenditures to the particular parts of the work being done upon which the management deems it necessary to have accumulated any specific information. In the forms submitted, there are sub-accounts representing different parts of the operation within the station, sub-dividing it into boiler room, engine room and the electrical generating room; similarly it sub-divides the work outside, the inspection, trimming of lamps, lines, the additions to the plant, whether within the station or outside, and also seeks to separate the different classes of service. It is, of course, important that the returns made upon these orders be in accordance with the instructions contained in the order. Thus, for instance, an order authorizing the inspection of lines should not have charged to it or reported against it the coal consumed under the boilers, and experience has demonstrated that employees very soon become accustomed to reporting and subdividing their work in accordance with the designations of the orders under which they are acting, so that in practice the allotment of expenditures for labor, material or other expense becomes automatic, with the result that the bookkeeper can indicate at any time the amount expended for any sub-account. By using subsidiary ledgers for this purpose, arranged similar to blank or Form No. 1, which, as will be perceived, is a re arrangement of the items upon the Form No. 2, and total up month by month or day by day as they may be recorded therein, the costs of each sub-account. Periodically, say monthly, the totals of these accounts are transferred either to asset accounts or to the debit of the revenue accounts, according to their character. The bookkeeper in debiting the returns on these orders to their various accounts, must make corresponding credit to certain other accounts; labor to credit of labor account; material or merchandise to credit of material or merchandise accounts, sub-divided as it may be; expense to expense account, and the totals of the credit of these accounts must, of course, balance with the totals debited to the accounts represented by the orders. When the labor is paid, the amount paid is debited to the labor account, thereby checking the accuracy of the pay rolls, which may be made up either from the returns upon the orders or by independent returns, but all labor represented by either the independent returns, time sheets or otherwise as may be used.

must balance with the accounts credited as above to labor account, and debited to the accounts represented by the various orders.

In the detail working under these orders through a number of employees, means of obtaining material and making returns under and to these orders become necessary, and where a large number of employees are engaged, these necessarily require the adoption of other forms or blanks, as, for instance, the requirement of material for the execution of any order necessitates that an application be made by the employee needing that material to the store room or storekeeper, where such material is kept on hand, or through whom it will be purchased if need be. In the system described, this becomes what is known as a requisition, blank No. 6, and in filling out such requisition the employee requiring the material quotes thereon the No. of the order on which he intends using it. Similarly in making returns of labor or time, the time ticket or labor return blank specifies the order No. authorizing such labor. Blanks or forms authorizing the return to storeroom of any surplus material that may have been taken out on an order, also recite thereon the order No. to which it is to be credited or upon which it is returned. In all these returns or reports, besides quoting the No. of the order, the accounting of such order is also recited, the object being to prevent the error of charging a wrong account through a mistake or transposition of the order numbers. Revenue accounts may also and in the system herein referred to are sub-divided or classified into various accounts of service from which the revenue is obtained, as, for instance, alternating current incandescent lighting, alternating current motor service, direct current motor service, arc lighting, etc., and this subdivision may be made as minute as desired.

Dealing with a large number of customers, it is important that means be adopted whereby none shall escape from the grasp of the bookkeeper or collector. Therefore no customer should be connected with the service lines except under an order, as above described, authorizing such connection and supply of the service called for. Upon completion of such order, it is returned to the bookkeeper, with notation thereon that connection has been made and supply of service begun. Meanwhile, that is as soon as the order to make connection has been issued, the contract signed by the customer upon which the order has been issued, is transmitted to the bookkeeper, who immediately opens in his ledger an account with such customer. On the return of the completed order, the bookkeeper notes in his ledger at the customer's account, the date of starting, which is also marked upon the contract. The customer's contract is not filed or put away or considered as being in operation, until such notation has been made. As an additional precaution, when the account is opened in the ledger, a card similar to Form No. 7 is prepared by the bookkeeper, giving the customer's name, address, ledger folio and number of contract (and all contracts are numbered serially), character of service, and generally the main details of the contract and service. This card is filed according to ledger folio, and accumulates the record upon which the debit side of the customer's account in the ledger is created. In cases where meters require to be read, these cards constitute the guide to the meter readers as to what meters are to be read. In sending out accounts to customers for service, every card must be accounted for by an invoice, and the fact of such invoice rendered noted thereon. In other words, the card is used to make out the invoice against the customer and the invoice is used to enter the account in the ledger, and every account in the ledger must be represented by an invoice.

The use of the method of making the entries in the day book and ledger from the invoice instead of making the invoice from the record book, is to hasten the transmission of accounts to customers, in order that they may not have any cause of complaint for delay in the opportunity to pay their accounts. In practice, the invoices are made out during the month as far as possible, leaving only the final entry to be made when the amount of the invoice has been determined, so that it becomes possible to transmit a large number of accounts within practically one day after the meter readings have been taken. The cards, in fact, constitute the history of the relations of the customer with the company, and at a glance show the variations in the use of service, for, as will be perceived, they are made to cover the year's transactions. They apply equally well for "flat" rate customers as for meter customers, though they are for recording meter readings. In the case of meter customers, they indicate the variations of use and afford a guide to the bookkeeper to enquire into the accuracy of the meter reading reported; any falling off or unusual increase in the use of the service as indicated by a reading immediately attracts the attention of the bookkeeper or billing clerk, thereby causing him to institute an immediate enquiry into its accuracy. In the case of "flat" customers, it declares at once the proper amount of the account to be rendered, by the record of the account previously rendered. The debits to customers are credited to the several sub-divisions of the revenue accounts, that is, the customer may be using several kinds of service, the amounts for which are debited to his account, but credited each to the revenue account to its individual class of service. This results in determining the revenue obtained during any period from each kind of service, the total of all, of course, representing the entire revenue obtained and offsetting the expenditures made therefor.

Companies having to deal with a large number of customers and various classes of service, and varying discounts, resulting from special or large consumption, will necessarily require for the convenience of the cashier, a secondary or subsidiary cash book in which can be noted the special discounts or allowances made, as well as the cash received for the various classes of revenue. A form of such cash book is indicated in blank No. 8. This cash book, or rather entry book, for the receipt of cash and discounts, applies only to discounts stipulated in the contract. Other allowances, rebates or credits are made only by authority of order issued specially therefor in each case.

Assuming this system of accounting to have been properly and carefully carried out to the end of the fiscal year, we would now have before us the total revenue from the business in its various classes. On the other hand, we would have the total cost of operation and maintenance, general expense and the total expenditure on capital account for the year; taking the total revenue derived and deduct from that the total cost of operation and maintenance, will give the gross profit. From this gross profit is to be deducted the general expense. The general expense account should include only such items as are purely general. By that I mean expense which cannot be charged to any specific working account, and is purely general in its relation to the business, such as interest, office expenses, directors' fees, salaries of officials, legal expenses, travelling expenses, for instance expenses incurred in attending Electrical Association conventions. Deducting the general expense from the gross profit will give the net profits of the business for the year, exclusive however, of depreciation. This question of depreciation is usually determined by the management. It always has been a much discussed question, and authorities find it very difficult to agree on a uniform method of application, the changing value of apparatus being so widely different. However, one of the definitions of depreciations, given by E. Hartley Turner as "The re-payment of capital out of the total gross revenue earned during a given period of such proportion of the original capital outlay as has been absorbed or consumed in earning such gross revenue" is very good, could the amount so absorbed be readily determined. A definite plan, however, is to apply to property in which a residue of value under any circumstances must remain, a graduated percentage upon its changing value as representing depreciation. The amount of this depreciation, however, will be governed to a great extent by the amount of the expenditure on maintenance account.

In the presentation of this paper, I have endeavored to follow out the question of Central Station Accounting from a business standpoint solely. With this in view, it has been confined almost entirely to the question of the method of ascertaining costs of generation and distribution, and recording from whence revenue has been derived and the methods of assuring the obtaining of all the revenue derivable. I have assumed that the important features are the knowledge of costs and the sources from which the revenue can be most profitably obtained. The question of purchase of material and the recording of these purchases have not been touched upon, this method being practically similar to all lines of business; neither has reference been made to the obtaining or keeping of records pertaining more particularly to the Engineering Department, for the reason that this subject has been exhaustively considered in a paper entitled, "Some Central Station Economics," submitted by P. G. Gossler at the annual convention held in Toronto in

1897. Whilst, no doubt, the system herein described may appear elaborate and extensive in detail, and perhaps seem to entail expenditure for labor beyond the reach or desire of managers of small stations, I see no reason why the principle involved may not be used in any station at a slight expense. For while perhaps not requiring to employ all the sub-divisions indicated upon the blanks or forms shown, yet many of them can be utilized and put into practice with such modifications as the local conditions demand without imposing upon the manager or employees any labor or expense beyond that which can be afforded, and if I have succeeded in conveying ideas and information that may serve towards the adoption of a general system of Accounting for Central Station practice as suggested by the authorities referred to in the beginning of my paper, I will feel myself amply compensated.

RAILWAY ENGINEERING.

The Engineering News, New York, says recently: "We here have presented in book form a series of articles on railway construction originally published in The Canadian Engineer. The author has had a long and varied practical experience in railway work; and while he quotes freely from the late A. M. Wellington's 'Theory of Location,' and from other standard works on this subject, his aim is to serve those who wish to acquire some general information on subjects heretofore separately treated. In the first chapter he deals with fundamental considerations and statistics, chiefly applicable to Canadian railways. Train, curve and grade resistance and their cost, and vertical and horizontal and transition curves are treated in the next two chapters. Under Surveys, we have the organization and methods for making reconnoissance, preliminary and final surveys, and some of the methods of passing obstacles. 'Roadbed Construction' covers waterways of various types, with designs for such structures and approximate cost, and includes large bridge foundations and the methods for sinking them; wooden trestles are treated at full length as still desirable where wood is abundant and other material unavailable. Foundations on land and in water are separately treated; the various methods are described and the approximate cost is given in many cases. The laying out and measurement of work is illustrated by diagrams and text, and notes are included on the methods of payment and classification of materials, etc. The sixth chapter deals with Canadian railway law, under the Railway Act; and Part II. of the book is devoted to track details. The work, taken as a whole, condenses into a small compass much information that will be useful to young railway engineers."

THE DART UNION COUPLING.

We call the attention of our readers to the advertisement that appears now for the first time in a Canadian journal, of the E. M. Dart Manufacturing Co., Providence, R.I. This company is engaged in the manufacture of several excellent steam appliances that have won their way to the front by merit. The most conspicuous is the Patent Union Coupling, which is claimed by all parties to be "the best." One of the illustrations in the advertisement shows the patented features, which will be readily understood by steam users. The connecting parts marked Dart Patent, April 1st, 1890, are made of bronze, the other parts are malleable iron. This company has supplied to the Brooks Locomotive Works, Dunkirk, N.Y., fifty thousand of these couplings in the past four years. These couplings are now being furnished to the largest industrial works, including locomotive builders, railroad companies, factories, breweries, ship builders, miners, steam fitters, gas companies, plumbers, and others, for use in connecting pipes, for the conveyance of steam, water, gas, oil, air, etc. The E. M. Dart Mnfg. Co., in offering to the people of Canada this excellent device, can give assurances, born of experience, that the meritorious features have been subject to the "crucial test of time," and no risk is taken in buying the goods. We learn that the company contemplates having these goods on sale with the prominent jobbing houses of Canada soon. All enquiries for prices and discounts will be promptly answered by addressing E. M. Dart Mnfg. Co., Providence, R.I., U.S.A.

LEAKING VATS.

Editor CANADIAN ENGINEER:

Will you kindly tell me what to apply to the inside of cider tanks to prevent the cider soaking through the wood. I have lost hundreds of gallons in this way, and can find no remedy.

[The only satisfactory method, so far as we know, is to apply a special enamel to the inside of the tanks, such as brewers use. We have sent you by mail the name of a dealer in brewers' supplies, whom we can recommend. Ed.].

SMOKE CONSUMPTION.

The Montreal Board of Trade has for some time used anthracite screenings as fuel in making steam for light and power. A forced draft is necessary to do this, which causes a considerable quantity of the ash, small particles of slate, and some unconsumed coal dust to escape at the top of the chimney in the shape of fine hard grit. This proved troublesome, not only to the Board of Trade and their tenants, but also to others in the neighborhood, and it was decided to at once put a stop to it. This has been accomplished most effectually in a novel manner, the sparks or grit as they leave the fire are caught and separated from the hot gases before they pass through the tubes of the boiler, thus preventing the accumulation of dust or ashes in the tubes and maintaining the boiler in its most efficient condition at all times. The sparks or grit, after being separated from the hot gases, are then immersed in water and conveyed outside the building by means of a special hydraulic conveyor, and are then separated from the water and are ready to be carted away. The water is then returned to carry out more ashes and grit. The system was thoroughly tested on one boiler for six months before being applied to the remainder of the plant, since which time it has been inspected by several prominent engineers, who all say that it is the best device for the purpose that could be thought of. John J. York, superintendent and engineer of the building, is the inventor of the system, and he is now preparing to take out patents on it.

CORRECTION.

In the issue of The Canadian Engineer for June, by a typographical error in John S. Fielding's letter on "Dam Building," the formula "$31.25h^{2}$" was made to appear as "$21.25h^{2}$."

THE V. & B. PIPE WRENCH.

Vaughan's improved positive grip pipe wrench combines lightness and strength, as well as durability, and its construction is the most simple, and the least complicated of any practical pipe wrench on the market. As will be seen from the above cut this wrench consists of only two pieces, which are drop-forged from bar cast steel; there is no malleable nor wrought iron used in its construction. It is solid cast steel from end to end; it has no threads to rust and wear out, nor springs to break; it cannot lock nor wedge on the pipe, and will release its grip instantly when the pressure on the handle is removed. The teeth are in a line tangent to the circumference of the pipe,

which combined with the oscillating angular toothed jaw, absolutely prevents crushing or slipping on the pipe. The jaws are oil tempered and the teeth can be sharpened with a file when dull. This wrench is especially adapted for use in limited spaces, such as narrow ditches, pump work in wells, pipe work for irrigation, wind mill pipe work, and for general use around agricultural machines. Every mechanic should have one. For screwing in stud bolts in steam pumps and engines. The makers claim for the V. & B. pipe wrench, simplicity of construction, combined with lightness and strength, and its positive rigidity when under a strain, and wherever it can be used

there is no wrench that excels it. Every wrench is warranted. This wrench is equally suitable for square and hexagon nuts, iron rods, etc.

Length.	Capacity.
10 inch pipe	⅛ to ¾
14 inch pipe	¼ to 1½
18 inch pipe	¼ to 2
24 inch pipe	½ to 2½

For discounts and further particulars address Aikenhead Hardware Co., Toronto.

NEW CATALOGUES.

Lundell Fan Motors, catalogue 66; Sprague Electric Co., New York. Jack & Robertson, Montreal, sole agents for Canada. This is a most attractive booklet of 40 pages, bound in green and gold, and profusely illustrated.

Electric Power—The Lundell Motor, Catalogue No. 58; The Sprague Electric Co., New York. Jack & Robertson, Montreal, sole agents for Canada; 70 pages; paper; illustrated.

Greenfield Flexible Metallic Conduit, Catalogue No. 63; Sprague Electric Co., New York. Jack & Robertson, Montreal, sole agents for Canada. This valuable specialty is very fully illustrated in some 20 pages, paper.

FIRES OF THE MONTH.

July 5th. Winnipeg Trunk and box factory; loss, $5,000; insurance, $1,200.——July 12th. Hourd & Co.'s furniture factory; loss, $8,000; insurance, $4,000.——July 24th. Str. "Mistassimi," on Lake St. John, Que.; loss, $50,000.——July 26th. J. F. Beckhan's saw mills, Holmes & Arpin's box factory, D. Gagne's door and sash factory and W. S. Scott's cabinet factory, Montreal; loss, $13,000.

LITERARY NOTES,

"Transformer Design;" a treatise on the design, construction and use of transformers, by Geo. Adams, A.I.E.E., A.M.I.M.E.; cloth, 75 pages, 34 diagrams: Spon & Chamberlain, New York.

The weekly news edition of the Street Railway Journal is a new and most welcome recruit to the ranks of technical journalism. This edition is devoted primarily to the publication of street railway news and current happenings related to street railway interests.

"A Practical Handbook on the Care and Management of Gas Engines," by G. Lickfeld, C.E., authorized translation by G. Richmond, M.E. This compact little volume also contains instruction for running oil engines. Cloth, 113 pages, illustrated: Spon & Chamberlain, New York, publishers.

"Small Accumulators; How Made and Used," is an elementary hand-book for the use of amateurs and students, edited by Percival Marshall, A.I.,Mech.E. This is a scientific handbook of great value to the class of readers for whom it has been specially prepared.

We have received the Transactions of the Association of Civil Engineers of Cornell University, Vol. VII., 1898-99. This volume contains addresses by non resident lecturers, miscellaneous papers, constitution and list of members of the association. Among others these are interesting papers; Notes of th Use of Concrete in Dams; Data of Stream Flow in Relation to Forests; Locks and Lock Gates for Ship Canals, etc.

Wallace Bentley, A.I.M.E., Halifax, Eng., is the author of a most valuable series of technical works. Rules and definitions specially arranged for the use of students in the engineering subjects is a surprisingly full store of exact information contained in so small a compass as to be very convenient for reference. In our column, "The Practical Man" we quote a few paragraphs on Toothed Gearing, which will show the reader the value of these works of reference. Questions in Applied Mechanics (with answers), is a companion volume, as is Questions in Machine Construction and Drawing. Sketches of Engine and Machine Detail, is a cloth bound volume of some hundred pages, each crowded with carefully prepared drawings of details which cannot but be of great assistance not only to technical students but to everyone who wishes an exact knowledge of engine and machine details.

We have on our desk the calendar of the School of Mining, Kingston, Ont., for 1899-1900, which contains a full announcement of the work of this progressive institution. Wm. Mason, Bursar, School of Mining, Kingston, Ont.

The illustrated supplement to the Nelson Miner presents a great variety of views of the town of Nelson and surrounding localities in its numerous illustrations, and in the text gives a good deal of information as to the people and places shown.

The Department of Public Works, St. John, N.B., has issued the Engineer and Superintendent's Report on Sewerage and Water Supply. This work is in charge of Wm. Murdoch, C.E., and all engineers must feel interested in the thorough manner in which everything is carried on. Mr. Murdoch's methods in cleaning the city water mains have been fully described in The Canadian Engineer in the past. We shall give some of the more recent results in the early future.

We have received from the Civil Engineering Society of Perdue University, La Fayette, Ind., the Proceedings of the Perdue Society of Civil Engineering, 1898. There are some interesting articles on irrigation problems, and a discussion of block asphalt under the title of The Coming Pavement. We learn that paving blocks of crushed stone and asphalt were first manufactured in San Francisco in 1869. Since that time the methods of manufacture and the necessary machinery have been perfected until it became possible to manufacture them at prices that would permit of competition with other pavements. For the past thirteen or fourteen years the tests of this pavement have proved that it was no longer an experiment. Baltimore has a sample of the asphalt block pavement that has been in use for fifteen years, and is still in good condition. The blocks are 4 in. by 4 in. by 12 in. in size, composed of about 85 per cent. crushed stone and 15 per cent. asphaltic paving cement and subjected while at a high temperature to a pressure of 120 tons to the block. The blocks weigh eighteen pounds each; they are laid crosswise of the street, making a pavement 4 inches deep. The cost is about $2 per square yard.

THE ROYAL ELECTRIC CO., LTD.

The annual meeting of the shareholders of the Royal Electric Company was held July 18th. Among those present were: D. Morrice, Lieut.-Col. Strathy, F. L. Beique, C. S. Campbell, H. B. Rainville, Herbert Wallis, G. F. C. Smith, A. F. Riddell, J. R. Meeker, G. R. Marler, John Date, Edwin Hanson, Frank Newman, A. Brunet, W. H. Browne, the manager; James Wilson, Mr. Morrison, G. H. Smithers, Edward Rawlings, H. G. Strathy, George Caverhill, and L. McI. Spackman.

The manager, W. H. Browne, made some explanations in regard to the operations of the company since its inception and during the past year. He said that, in the electrical business, inventive genius was so prolific that the plant or apparatus for manufacturing electricity soon became obsolete. Hence, during the existence of this company, $1,800,000 of equipment had become useless, or superseded by improved machinery and methods. The whole of that $1,800,000 had not been written off, but $600,000 to $800,000 had, and, while there was certainly a million dollars in the nominal assets, which was really not in existence for any practical purpose, he thought the proper thing to do was to distribute the loss over a number of years, as they had been doing. Speaking of underground conduits, Mr. Browne said the time was coming, and they soon must meet the necessity. The cost of total conversion from pole wiring to conduits would be $1,500,000, but entire conversion was not necessary, as in some of the residential quarters it was not called for. He explained that, notwithstanding the large outlay for conduits, the expenses of maintenance would be sufficiently reduced to pay the interest on the outlay. The prices of current in Montreal would not be reduced to the point consumers expected, even if the source of supply was the water power of Chambly.

Colonel Strathy nominated as directors the following gentlemen: Col. J. A. L. Strathy, D. Morrice, James Wilson, H. B. Rainville, R. Forget, J. R. Meeker, A. Brunet, F. L. Beique and George Caverhill.

From last year's board there were left out of this year's nomination, the following: Hon. J. R. Thibaudeau, A. R. Macdonell, H. S. Holt, Edwin Hanson and Robert Cowans.

Those nominated were elected, though D. Morrice and F. L. Beique refused to act. At a subsequent meeting of the directors, R. Forget was elected president, and J. A. L. Strathy vice-president.

The following figures are from the fifteenth annual report of the Royal Electric Company for the year from May 31st, 1898, to May 31st, 1899:

The gross amount for the year to credit of revenue accounts aggregated	$1,113,770 87
Expenditure for labor, materials, operation, maintenance, and general expenses	791,486 58
Balance	$ 322,284 29
Less interest and fixed charges	54,600 11
Net profit for the year	$ 267,684 18
There have been declared four quarterly dividends of two per cent. each to the total amount of	120,000 00
Leaving a balance of	$ 147,684 18
From which are to be deducted the following:	
Sundry debts uncollectible or of doubtful value, charged to profit and loss account	3,101 66
Depreciation of merchandise, and factory product, on hand	8,777 99
Apparatus and plant displaced and withdrawn from use, and of dimmution in values of sundry items of assets	123,870 16
Added to the credit of profit and loss account	11,934 37

HOT WATER HEATING.*

BY P. TROWERN.

In my last address I told you about the different plans which were adopted by the people in different countries, for heating their houses. The furnace and plans of laying the pipes, invented by Mr. Perken for heating large buildings in England and other countries were brought here in the year 1850 from London by Mr. Howard, to this asylum, and fitted by Mr. Garth of Montreal, and after I took charge of it in 1850 it did good duty for 34 years; in 1890 I began to change the coil furnaces for tubular boilers, in the main building; we have now only four furnaces left in cottages A and C, which I will soon change for two boilers, although they have worked well for the past cold winter, keeping 100 people warm, with 60 tons of coal. I told you that I would give you my reasons for changing. Fully twenty years ago I saw a good change could be made after making and repairing 100 coils, and every year the brickwork had to be repaired, and made new, which became expensive, and took so much of our time in the summer, which seemed so short, in keeping new work and repairs in order for the winter.

I have shown you in my diagram of the furnace that the two pipes at the back are the flow or hot water pipes rising out of the coils, inside and outside ones; the two in front are the return pipes with taps at the bottom and connected with each coil at the bottom. The pipes are connected with a cast-iron expansion cylinder, each one on a wooden pedestal in the ward; each coil has a cylinder; the flow pipe connects with the cylinder as near as possible in the ward, in the bottom so that the cylinder becomes very hot at times, the return pipe also connects with the cylinder in the bottom and extends around the rooms for about 500 feet of pipe, and returns in the same recess together to the coil. In this form the water is always moving around while there is any heat in the furnace or bricks.

We will now look at our middle ward, which is about 30 feet above our furnace, this 30 feet of 1-inch pipe will hold one gallon of water at about 40 deg., or 10 lbs., and when heated to 212 deg. it will expand so that 21 gallons becomes 22, one gallon or 10 lbs. will become with the water in the cylinder 1534 gallons; the cylinder, however, is not always kept full, and if the return water be reduced in heat by one-half of the degrees it will be increased in weight by $3^1/_2$ lbs. (say 3 lbs.), which gives the motion to the return. If the 500 feet of pipe lies horizontally in the recess, not having a fall to the furnace, it will reduce the weight and motion in getting back to the coils; so you see what a small weight or force we have to keep up the circulation. We will now go to a ward about 30 feet higher, 60 feet above the furnace. These cylinders and pipes work better because of the height and weight being increased. Here we will observe the air is not admitted to the water anywhere, but when we pump in any to make up for waste, we after a while let out, by opening the tap above, whatever air may have gone in with it, and also any steam which may have formed on top of the water, we fill and supply them all with the pump. We will now go to the dome tank, 15 feet above, or 75 feet above the furnace; a cylinder and a coil of 1-inch pipes around a 20-foot diameter and 6 foot deep tank of water supplied by city waterworks. This furnace worked well, but the pressure was so great the coils would not or did not stand the same length of time as the others, because we had to keep a larger fire, the coils being larger and the pipes connected being about 1,000 feet each. We will now go to the basement. The expansion cylinders are about 15 feet above the furnace; and the 500 feet about 3 feet above the furnace; this gave more expense and labor to keep going than any other, one reason was, I was obliged to return the water to coils in the furnace under the floor and below the top of the furnace. I then lowered the furnace but found it too wet for the fire to burn well and raised it again; here I began to see that if I put in a boiler large enough I could stop four fires and have one to do the same amount of work much better, and get the same amount of pressure alike in all the coils by having an expansion of 100 gallons up by the large tank, and instead of supplying them with a pump I could supply them from the tank 75 feet above, 35 lbs. pressure; I then drew a plan for a 40-inch boiler, 8 feet long, with two 11-inch flues for the heat after passing under the boiler to come to the front and then go back to the smoke pipe behind on top of division plate through sixteen 4-inch tubes. I had a division plate behind and a smoke box in front; I had holes tapped in the top and sides for 1-inch pipes, the same pipes which were connected with the coils I connected with the boiler, but the expansion cylinders in the wards were full, and became a part of the heating pipes; I took up to the expansion cylinder two pipes, one flow and one return. The water in the cylinder is about the same level as in the tank, and a pipe from the bottom of the tank to supply the boiler with a check valve and supply tap near the side of the boiler, each pipe has a cut-off tap so that if any dirt or scales choke the pipes in the wards, we drain the pipes and cylinder, and then let on the full force, on the top of the expansion cylinder. Up by the tank we have a relief pipe to discharge into the tank should a large fire be put in too quickly; the first boiler has been working for the last ten years without any repairs or changes, the same set of bars, burning hard coal, large egg.

We have now in the Toronto Asylum for the Insane, ten heating boilers and seven for giving hot water and four coil furnaces for heating in the two cottages, and three boilers for our greenhouses.

*From a paper read before the Canadian Association of Stationary Engineers.

—Sixty of the rollers and heaters in the forge department of the Ontario Rolling Mills, Hamilton, Ont., struck, July 3rd, demanding, it is understood, sixty cents more a ton piece work. The men's demands were granted, and they returned to work in a couple of days.

—The construction of a canal between Lake Ashawaken, on the head waters of the Ottawa, to a point on the Gatineau river, a distance of some seven or eight miles, is being discussed. A large portion of the distance is watered by small lakes, leaving but a few miles of actual canal to be excavated. It is claimed that the freshets on the Ottawa are not of sufficient duration to take out the timber from the far northern regions in one year, and that no lumberman would hold limits and pay dues under these circumstances. The line of the proposed canal is just about twenty miles south of the height of land, latitude 48, and longitude 76, or about one hundred miles north of the present farthest north operations. Altogether the canal would, it is said, open up for operation about ten thousand square miles. It is rumored that the project may be laid before the Quebec Government for the purpose of obtaining a subsidy.

CANADIAN ASSOCIATION STATIONARY ENGINEERS' CONVENTION.

The convention opens at Berlin, Ont., August 15th.

The following is the official programme: Tuesday, August 15th.—11 a.m., reception of delegates, Mayor's address of welcome; 2 p.m., meeting of committees.

Wednesday, August 16th.—9 to 12 a.m., general business; 2 p.m., reading of papers and discussions; evening, open air concert by B.M.S. band in Victoria Park.

Thursday, August 17th.—9 a.m., business of convention continued; 2 p.m., election of officers and other business; 9 p.m., banquet at the Walper to the officers and delegates.

ARCHIBALD W. SMITH.

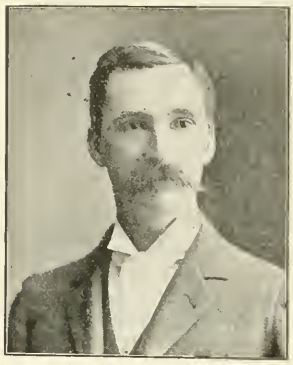
The publishers of The Canadian Engineer have pleasure in announcing the addition to its staff of Arch'd W. Smith, so well and favorably known for some years past as manager of the engineers' supplies and machinists' tools department of the Aikenhead Hardware Co., Adelaide street, Toronto. Mr. Smith was born in Quebec city in 1870, and attended the public and high schools of that city till 1884, when he entered the employ of Herman Young, now H. & J. Young, Quebec's leading hardware house. While in the service of this house Mr. Smith

ARCHIBALD W. SMITH.
C. H. Noble, Toronto, Photo.

was associated with W. H. Wiggs, founder of the Mechanics' Supply Co., Quebec, and to him he owes very much of his subsequent success in handling the large business in engineers' supplies and machinists' tools, which he has just left for newspaper work. In 1890 Mr. Smith came to Toronto, taking a position with Aikenhead & Crombie, and later when the business of this firm was taken over by the Aikenhead Hardware Co. Mr. Smith took charge of the department of machinists' tools, engineers' supplies and kindred lines, which has so flourished under his care as to fully justify the company in styling itself "Canada's leading tool house." Just previous to leaving the Aikenhead Co. Mr. Smith was presented with a beautiful gold chain and locket by Wm. Martin on behalf of the employees of the company. Thos. E. Aikenhead spoke on behalf of the company, expressing regret at the severance of a connection which had not only been very pleasant but materially profitable.

SURGEON-LIEUTENANT T. A. BERTRAM.

The town of Dundas, Ont., has long been known as the headquarters of the famous machine tool builders, John Bertram & Sons, and of recent years it has added the distinction of being the home of Canada's best marksmen. The two circumstances have also some relation for Pte. Hayhurst, who captured the Queen's Prize some years ago, was employed by John Bertram & Sons, and Surg. Lieut. Bertram is John Bertram's son. T. A. Bertram is 33 years of age, and was born in Dundas. He received his education at the common and high school here, when he went to Queen's University, Kingston, Ont., where he graduated and received his M.D. in 1886. He then went to London, Eng., and pursued his studies, and also attended the Royal College of Physicians and Surgeons, Dublin, where he graduated. On returning to Dundas, he went into partnership with Dr. Holford Walker for a few years. Afterwards, Dr. Walker retiring, to establish his present hospital in Toronto, he continued his Dundas practice. Dr. Bertram's brothers, Major Alex. Bertram and Staff-Sergt. Henry Bertram, members of the firm of John Bertram & Sons, are also good shots at the ranges. Dr. Bertram is a keen curler and has always distinguished himself in contests with



SURGEON-LIEUTENANT T. A. BERTRAM.

other clubs, bringing honor to the Dundas club. While at Queen's University he distinguished himself as an athlete, carrying off the championship cup for two successive years. The following is the record made by Dr. Bertram at Bisley: Queen's prize, place 26, £12 and badge; St. George, £2; All Comers' Aggregate 1st. cup valued at £250 and £15 cash; Corporation City of London, 1st prize, £25; Grand Aggregate Dominion of Canada Challenge trophy and National Rifle Association gold cross and £20, entitling the winner to have the letters G.C. after his name; Volunteer Aggregate 1st prize, Hop Bitter Co.'s challenge trophy and £15; Daily Graphic, 6th place; £5 and three framed sketches valued at 10 guineas each. In the Graphic, Daily Telegraph, Martin's Challenge Cup and other events he won a number of prizes. In the unlimited series he won £13. All the winnings in the above list are divided amongst the team, excepting the last one. Following are the scores made by Dr. Bertram in the principal competitions, together with the possible scores:

Grand Aggregate, 360 out of possible 385.
Volunteers' Aggregate, 164 out of possible 175.
All Comers' Aggregate, 196 out of possible 210.
Queen's, 324 out of possible 380.
Martin's Cup, 34 out of possible 35.
Alexander, 66 out of possible 70.
St. George's, 65 out of possible 70.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports from Great Britain of interest to the metal trades in June, 1898-99 and the six months ending June, 1898 and 1899:—

	Month of June,		Six Months to June	
	1898	1899.	1898.	1899.
Hardware	£1,416	£1,855	£10,312	£9,450
Cutlery	4,797	5,150	19,497	26,120
Pig iron	384	1,618	6,158	5,049
Bar, etc	1,516	2,192	5,650	5,716
Railroad	–	8,188	6,072	20,695
Hoops, sheets, etc.	4,005	16,177	16,255	38,835
Galvanized sheets	3,187	11,087	23,845	30,403
Tin plates	11,319	22,718	71,052	77,004
Cast, wrought, etc., iron	1,086	5,279	14,309	17,515
Old (for re-manufacture)	1,571	1,086	3,075	1,659
Steel	3,513	6,021	27,642	30,547
Lead	4,127	6,821	11,032	21,469
Tin, unwrought	1,505	2,250	9,673	9,517
Alkali	4,238	3,365	20,872	16,002
Cement	1,703	3,692	9,883	12,705

Industrial Notes.

The Copper Crown Mining Co. is building a smelter at Pictou, N.S.

Welland, Ont., will spend $8,000 on a town hall, not $2,000, as stated in a former issue.

James Fleming, St. John, N.B., has the contract for the boilers for the new Cushing pulp mill.

The International Convention of the Brotherhood of Locomotive Engineers met in St. John, N.B., July 27th.

A by-law for raising $40,000 for the building of a waterworks system in St. Mary's, Ont., was carried July 24th.

The Georgian Bay Cement Company is building a switch from the main line of the C.P.R. to William's Lake.

The National Iron Moulders, in convention at Indianapolis, U.S., have selected Toronto as the place of next meeting.

In boring for oil at Athabasca Landing, natural gas has been struck at a depth of 1,800 feet. The flow is large and very steady.

John Addison has bought the East Hamilton Co.'s property, Hamilton, Ont., including the East End Incline Railway and 40 acres of park, for $22,000.

A. E. Domville, of the St. Thomas Car Wheel Co., has been made a director in the International Car Wheel Co., lately formed, with a capital of $15,000,000.

W. B. Cleveland, T. A. Neef, and H. M. Stowe, of the Protected Rail Bond Co., of Cleveland and Philadelphia, are looking for a suitable location for a factory.

The International Correspondence Schools, Scranton, Pa., U.S.A., are offering special courses in mechanical and architectural drawing, book-keeping, stenography, and the English branches.

The Dowling Milling Co., Edmonton, N.W.T., has placed an order with The Goldie & McCulloch Co., Ltd., Galt, Ont., for the machinery in a new 175-bbl. flour mill, including engine and boiler.

Two large 400 or 450 h.p. cross-compound Wheelock engines, built by The Goldie & McCulloch Co., Ltd., Galt, Ont., have recently been placed in the power house at Bond Lake, Ont., for the Metropolitan Street Railway Co.

It is reported that Charles Leonais, Montreal, has sold several large tracts of spruce limits, situated on the north shore of the St. Lawrence, below Quebec, to a United States syndicate, for a large sum. Saw and pulp mills are to be constructed.

The Asbestos and Asbestic Company has taken out a writ of injunction against the William Sclater Co., alleging that the company defendant unduly uses the word "asbestic," to which plaintiff claims to have a sole right. The sum of $10,000 damages is also demanded from defendants.

J. W. Pyke, T. P. Howard, W. Ross, B. Shepherd, and R. A. E. Greenshields, Montreal, have received a Quebec charter as the Eclipse Acetylene Gas Company, with a capital stock of $50,000, to manufacture and construct machines used in the production of acetylene gas from calcium carbide.

The St. Thomas Times professes to be informed of the conditions on which the Standard Oil Company of the United States has gathered in the Ontario Natural Gas and Oil Company that has controlled the gas fields from which Detroit homes are being supplied with natural gas. The purchase price, it says, was $600,000, and, as there are only 25 shares, which sold in the original company at $600 each, the stockholders realize $24,000 for each share.

At Calumet, on the Ottawa river, about fifty miles above Ottawa, says The Montreal Star, there is a large floating sawmill, operated by steam and equipped with the most improved machinery; it can be floated anywhere there is a sufficient depth of water. This mill is owned by J. H. Dansereau, Vercheres, Que. His object in constructing the mill was to do away with the cost of towing logs from the mouths of the different tributaries of the Ottawa, between Ottawa and Grenville.

James Clemes is locating a saw mill at Grand Prairie, B.C.

A large pulp mill is to be built it is said by M. Menier at Macastey Bay, Anticosti.

S. F. Peters is architect of the new College of Pharmacy building, Winnipeg, Man.

Stewart & O'Leary have the contract for section 4 of the main drain, Ottawa, at $91,177.

It is reported that a Portland cement works will be established at Winnipeg this year by S. Walker.

Owen Sound Portland Cement Co., has just put in a 400 h.p. compound Goldie & McCulloch engine.

William Kennedy, Sons & Co., Owen Sound, Ont., are building a new moulding shop and enlarging their plant.

The Department of Lands and Works, Victoria, B.C., is building schools at Greenwood, Ashcroft, Slocan, Revelstoke and Fernie, B.C.

A by-law in aid of artificial stone works, which Arthur Jarvis proposes to establish in Belleville, Ont., is to be submitted to the ratepayers.

I. Matheson & Co., Ltd., New Glasgow, N.S., are running their plant night and day. This firm is now maker in Canada of the famous Case propellors.

The erection of a condensed milk factory is engaging the attention of some of the Sussex, N.B., citizens and may result in the establishment of such a plant.

The stove mounters in the stove foundries in Hamilton have had their wages advanced during the past month; in some cases the advance amounted to 25 per cent.

The plumbers' strike, Winnipeg, has been practically settled by the acquiescence of nine out of the ten employing concerns in the city to the wages asked by the men.

The large brick addition to the R. McDougall Company's moulding shop, Galt, Ont., is about finished. Other enlargements are contemplated on this property.

Cowan & Co., iron founders, Galt, Ont., will shortly commence the erection of a large addition to their works. It will be about 140 feet long, two stories high.

Wood Bros., Brantford, Ont., are turning the old Bain wagon works, recently vacated by the Verity Plough Co., into a flour mill; capacity, 100 to 200 bbls. a day.

The Hardill Compound Engine Co. of Mitchell, Ont., Ltd., has been chartered to make the Hardill compound engine; chief place of business, Mitchell, Ont.; capital, $40,000.

H. C. Cox, H. Sutherland, W. H. B. Aikins, T. R. Clougher, and R. H. Warden, D.D., have been incorporated as the Canadian Camera and Optical Co., Ltd.; capital, $150,000.

The MacGregor-Gourlay Company, Galt, Ont., is raising the roof of its moulding shop 8½ feet. The building is 104 x 40 in dimensions. The offices of the firm will also be remodeled.

F. S. Henning a marine engineer, and William Pigott, a painter, Toronto, have invented a fire escape which is a species of hydraulic elevator on the exterior of the building.

J. Lee, W. P. Robinson, W. H. Jenkins, W. Kemp and Nellie T. Clement, Woodstock, have been incorporated as the Caster and Metal Stamping Co., of Woodstock, Ltd.; capital, $5,000.

A bridge is to be built over Thunder Creek, near Shellmouth, Manitoba, including the erection of two stone piers, and the necessary grading of approaches. Wm. S. Wallace, Shellmouth, is the clerk.

J. Patterson has finished the plans for Shurley & Dietrich's iron and brass bedstead factory, Galt, Ont., which will be erected on a plot of land adjoining the firm's saw works. The new buildings will be of stone.

The recently organized Berlin Rubber Mfg. Co., of which Jacob Kaufman is president, George Schee, manager, and A. L. Breithaupt, secretary treasurer, is now getting in shape to manufacture rubber shoes.

R. N. Sterling, F. S. Jackson, J. W. Ball, Phoebe Jackson, and R. F. Massie, Toronto, have been incorporated as the Diamond Machine and Screw Co., of Toronto, Ltd., to carry on the business of the Diamond Machine and Tool Co.; capital, $75,000.

The Trent Valley Peat Fuel Co. has its plant running on the Balsam Lake division of the Trent Canal. W. J. Sims is manager. In operation the plant is found to be even more economical than the promoters claimed.

The Pierre-Mahy Glass Works Co., Rahnsart, Belgium, will probably organize a branch to manufacture glass in Chatham, Ont. Local capital will be enlisted to the extent of about $30,000, half the proposed capital.

The Georgian Bay Portland Cement Co., Ltd., Owen Sound, Ont., is installing a 300 h.p. Goldie & McCulloch engine, and a large amount of other machinery. M. Kennedy is president of this company, and James Maitland secretary.

C. F. Sise, R. Mackay, C. Cassils, R. Archer, H. Paton, L. B. McFarlane, C. P. Sclater, Montreal, have been incorporated as the Wire and Cable Co., Ltd., to make brass, copper and other metal wires, cables, etc., and to make electrical supplies; chief place of business, Montreal; capital, $100,000.

The Canadian Office and School Furniture Co., of Preston, has extended its factory and put in new machinery which will increase the capacity of the works by one-third. The company has orders for the seating and interior fittings of the new seminary chapel of Quebec, and for the new court house at St. Thomas, Ont.

Brown & Sharpe Mnfg. Co. has issued an illustrated wall card, which should hang in every workshop aiming at turning out the best work. The card shows the leading lines of these famous tools, and carries also a pad of reference tables, which are of great value to mechanics. They include, decimal equivalents; inches, also millimeters; the sizing and cutting of gear wheels; circular and decimal pitches; tapers per foot and corresponding angles; drill list for machine screw tops; decimal equivalents of the numbers of twist drill and steel wire gauges.

Robert Bell, Jr., proprietor of the Hensall Engine and Machine Works, Hensall, Ont., has completed a large machine for making bricks composed of sand and cement. The manufacture of this particular style of machine is, Mr. Bell says, the filling of a long-felt want in localities where brick clay is not found; that bricks made of sand and cement are, in many respects, superior to those made of clay, possessing a handsomer appearance, and can be produced at about the same cost. The machine alluded to has been tested and proved satisfactory, and has been forwarded to destination at Vancouver, B.C.

The Buffalo and Fort Erie Bridge Co. is building the only foot and vehicle bridge above Niagara Falls. The bridge, or practically two bridges, is to cross the Niagara from a point between Buffalo and Tonawanda, to Grand Island across the island, and on to the Canadian shore. The eastern section was the one for which legislation was obtained from the American Government in October, 1898. The location of the bridge has been approved by the War Department of the United States; the contract has been let for $1,485,400, and already several piers have been built. The Canadian section will cross from the opposite side of Grand Island, to a point in Welland County.

The increased trade of the Dominion Bridge Company has decided the management upon building an addition to their works at Lower Lachine, Que. Throughout the United States and Canada the iron and steel business has for some months been growing in tremendous proportions, and the Dominion Bridge Company now feels the necessity of enlargement in order to meet the increased demand. The new addition to the works, which will be completed in about two months, will give the company an increased capacity of from 7,000 to 8,000 tons per year, or about forty per cent increase on their present output. When the new buildings are in operation, the company will employ from sixty to eighty additional men.

The old established business of Wm. Hunter, brass founder, Hamilton, has been taken over by J. N. Tallman & Sons, who intend to maintain the reputation of the founder while extending the scope of the business. This they are well qualified to do, as Messrs. Tallman & Sons are experienced brass and iron founders, and understand every department of their trade, and are men on whom the fullest reliance can be placed. Since taking hold of the business they have put in a new electric motor, a water mill, a babbitt metal furnace and other plant, greatly improving their facilities for turning out work promptly. While maintaining the old firm's reputation for first-class babbit metal, the new firm will pay particular attention to special brass castings.

The Northey Manufacturing Co., Toronto, has under consideration a change which, if made, will result in an addition of $250,000 to the present capital of the company, and will involve the employment of at least 150 additional men, and possibly 500. The move which is contemplated is an amalgamation with a large Montreal firm which manufactures hydraulic and other machinery. A third company may also be induced to join forces with these two and to locate in Toronto. This would bring the total capital of the company up to $150,000. The Northey Company has been steadily increasing its sales of late, and is now sending machinery in large quantities to the Maritime Provinces and British Columbia, in addition to having a very large trade in Ontario.

Owing to the rapid growth in their business, Darling Bros., "Reliance Works," Montreal, have erected an extensive addition to their machine shop. The new building is a substantial brick two-story structure fronting on Ottawa street, adjoining the original premises, and occupies what was formally yard room. It affords some five to six thousand more square feet of floor space. The lower flat has a solid cemented flooring, with the latest slow-burning process of ceiling. The assembling will be done on this flat, where a driveway enters the western end, and where travelling cranes are used for taking up completed work from any part, and expeditiously loading it for delivery. The blacksmithing work will be done in this fire-proof department. The business offices are on the second story, entering by a broad stairway from Ottawa street, and are handsomely finished in oiled wood, and comprise a general office, private offices, draughting room, lavatories, etc., all well lighted. The equipment of the whole shop is of the most modern character.

As noticed recently in this Journal, the engine-building plant of A. J. Nie (previously the Osborne, Kieley Co.), Hamilton, has been purchased by the Smart-Eby Machine Co., composed of W. G. Smart and J. E. Eby, who have reorganized and extended the business and are now turning out large orders in the engine and machinery line. Mr. Smart was, until the present connection was formed, with the Jenckes Machine Co., of Sherbrooke, and Mr. Eby was for some years with the McGregor, Gourlay Co., and Cowan & Co., of Galt, having been manager of the latter firm. The new firm has set to work energetically and has made quite a success of one of its specialties—the Webster engine for gas or gasoline, of which it has the sole right of manufacture for the Dominion. The firm makes also electric light high-speed engines, pumping machinery and special machinery to order. Orders are now being filled for the Canadian Colored Cotton Mills, the dyehouses of which are now being enlarged. The firm will be pleased to send their catalogue to anyone interested in gas engines.

From April to the end of July the aggregate value of building permits issued to manufacturing establishments in Toronto was $283,300, making a total of $535,000 from June, 1898, to the end of the same month this year. Among the firms who have expended during the past year or are now expending large sums on factory additions or new factory buildings in Toronto are, the Massey-Harris Company, $28,000, on new works; the Allen Manufacturing Company, $30,000; and J. B. Kay, $30,000; the Toronto Carpet Company, $50,000; the T. Eaton Company, $21,000; S. F. McKinnon, $52,000, for buildings and warehouses; the Carling Brewing Co., $12,000; Wilson, Lytle & Badgerow, $16,000; the Gerrard Heintzman Co., $14,000; Christie, Brown, & Co., $25,000; Brown Bros. Co., $40,000; the Toronto Type Foundry, $20,000; the Henry Kent Estate, $20,000; John Patterson, $15,000, the Consumers' Gas Co., $25,000; George Weston, $15,000. Other manufacturers have expended all the way from $1,000 to $10,000, while the soap factory to be erected by Lever & Co., it is estimated, will cost over $100,000.

Electric Flashes.

The Nelson Electric Tramway Co., Ltd., Nelson, has been incorporated.

Barrie, Ont., is installing a 150 h.p. Wheelock engine as part of its electric light plant.

The Holmes Electric Protection Co., Montreal, has been taken over and will in future be operated by the District Telegraph Company, under the general management of John Murray.

St. Thomas council has made a ten years' contract with the St. Thomas Gas Co. for lighting the streets with the Adams-Bagnall lamps of 2,000 c.p. at 25 cents per night, or 26 cents on a moonlight schedule.

The Peterborough Light & Power Co. is building its new power house, which is to be finished in October. It will be of brick and steel, 36 x 55 feet, and from it will be developed 1,500 h.p.

The Montreal Railway Co. has adopted the fender invented and patented by G. W. Sleman, Guelph, Ont., which the management consider the best fender brought to their notice. It is used on the cars in Guelph and has been recommended to the Toronto Street Railway by the Toronto city engineer.

A new company, to be known as the Lorette Electric Light and Power Co., has been formed at Lorette, near Quebec, and will undertake the lighting of that village and of the Indian and parish churches; $2,500 has been subscribed and the capital stock will be $10,000.

The Bear River, N.S., Electric Light and Power Co. is making arrangements for extending its services to Digby and intermediate points. This has necessitated the increasing of the capital stock to $75,000, and will probably involve the purchase of the plant at Digby, owned by Major Daley.

Letters patent have been issued incorporating W. H. Coleman, Andover, Mass.; A. J. Gordon, North Hatley, Que.; F. E. Lovell, Coaticook, Que.; Jacob W. Barnard and John H. Champion, Andover, Mass.; W. D. Currier, Lawrence, Mass., as the Eastern Townships Electric Co.; capital, $300,000.

The Light, Heat & Power Co., of Lindsay, is constructing its long distance transmission plant. The current will be carried from the company's water power at Fenelon Falls, a distance of 14 miles, into Lindsay and will be completed in October. The company will have 1,200 h.p. available from the new works.

Thomas Maynard has been appointed chief clerk in the master mechanic's office of the Grand Trunk Railway works, Montreal, vice Donald Robertson, who has resigned after a service of over twenty years as chief clerk in this department, to accept the position of assistant to manager and engineer Wanklyn, of the Montreal Street Railway.

Robert Surtees, C.E., of Ottawa, has made a report on waterworks and electric light for the village of Shawville. The cost of a waterworks system is given at $11,000; electric light, $4,000. The engineer estimates that waterworks would give a total yearly revenue of $1,273, while that from electric light would be no less than $1,900. At present Shawville is without fire protection.

In the Divisional Court, Toronto, recently, Chief Justice Meredith and Justice Rose gave judgment in the case of Kirkpatrick vs. Cornwall Electric Street Railway Company, an appeal by defendants from judgment of Chief Justice Armour in favor of plaintiff in a mortgage action for foreclosure and payment of $100,000. They held that the mortgage was valid, but that that part of the judgment directing payment of principal, interest and costs, must be struck out.

The B. F. Sturtevant Co., whose well known "chimneyless" factory is situated at Jamaica Plain, near Boston, Mass., is making an addition to its already large floor space for electrical work. Another story is being added to two of its shops, one 125 feet by 50 feet, and the other 100 feet square, both of which will be used for this purpose. The increase in this department has been enormous. The company is now making electric motors up to 125 h.p., and generators up to 100 k.w.

The Bell Telephone Co. is burying its wires in the principal streets in Hamilton.

W. B. Cleveland, F. H. Neff and H. M. Stowe, Cleveland, are said to intend starting an electrical supply factory in the old Wanzer building, Hamilton, Ont.

The Penfield and St. George Telephone Co. is applying for a New Brunswick charter, S. L. Dakin, L. Conners, Beaver Harbor, N.B., and John Doyle, St. George, N.B., are directors; capital, $2,000.

Dr. Pyne and H. M. East asked the use of Toronto streets to distribute power from the Anglo-American Electrical Supply Company to private consumers at 1½ cents per h.p. per hour. They say they would produce power within 18 months.

J. C. McLachlan, G. McLachlan, C. Millar, C. W. Vernon and R. B. Orr, M.D., Toronto, have been incorporated to deal in electric apparatus, gas engines and autocars as the McLachlan Electric and Gasoline Motor Co., Ltd.; capital, $39,000; chief place of business, Toronto.

The Deschenes Electric Company denies the story which has been started that the Metropolitan and Deschenes Electric Companies have formed an alliance and that the Metropolitan Company had bought out the water power of the Deschenes Company. W. H. Taylor, secretary-treasurer of the Deschenes Electric Co., stated that there was nothing at all in the story.

The Hamilton and Lake Erie Power Co. have renewed their offer to the city of Toronto for the supply of electric power for lighting and pumping purposes. In a letter to the mayor, S. C. Biggs, president of the company, says that nothing has been done in this matter and that the continuation of the delay will result in the loss of thousands of dollars annually in the next lighting contract. He says that his company can show to the satisfaction of council their ability to carry out any contract they may make.

W. J. Poupore, M.P., has a very extensive contract with the Lachine Rapids Hydraulic and Land Co. The contract will include the addition to the present wing dam of one thousand feet. This was included in the original plan, and the original charter from the Government provided for it, but the company only constructed a certain portion of it to see how they would get along, and now they find it necessary in order to get into deep water. The work is to be finished by the first of December next.

The City Council, Montreal, recently decided to request the city attorneys to take action to compel the Lachine Rapids Hydraulic & Land Company to remove their lights from the incinerator. A contract was given to the company to light the incinerator, and after the contract had been completed it was found that the Royal Electric Company had the right under its street lighting contract to furnish all of the electric lighting required by the city departments. As a result both companies have been maintaining lights at the incinerator and charging the city for them.

Some time ago American capitalists purchased the controlling stock in the North American Telegraph Company, owned by the Folger Brothers and the Rathbun Company. The telegraph company has been in existence twenty years and owns 1,000 miles of poles and from 3,000 to 4,000 miles of wire. W. Bampfield, of Montreal, has been appointed general manager by the new company in place of R. C. Carter, who was held the position since the company was organized. The company owns and operates the telephone and telegraph wires in Prince Edward, Hastings, Frontenac and several other counties in Eastern Ontario.

Recently there was in Niagara Falls, N.Y., a fierce fire at the power house of the Niagara Falls Power Co. The trouble was caused by some contractors who were blasting under the Buffalo transmission line near the Carborundum Company, who threw a bit of fuse wire over the transmission wire. This caused a short circuit and the blowing out of a fuse in the power-house. The blowing out of the power-house fuse ignited several barrels of lubricating oil that stood in the oil room. The employees of the power-house took things very coolly, and the switchboard tenders never left their stations, although the smoke was so thick that they could hardly see. A still alarm was sent to the fire department and in a short time the fire was under control. The principal damage resulted to the power cables and the insulation, and amounted to about $6,000.

The postoffice authorities recently experimented with mail collections by electric auto-cars. The electric delivery wagon built by the Still Motor Syndicate for the Parker Dye Works was used. The trip extended about 9 miles and was covered in one hour and three minutes, including 2-minute stops at each of the eleven postoffices on the route. The actual running time was not more than thirty-five minutes, just about half the time required by the ordinary mail wagon. The Syndicate has sent in a tender to the department for a mail wagon, capable of running from fifteen to twenty miles an hour, with a carrying capacity of 1,500 pounds.

A special general meeting of the shareholders of the Standard Light and Power Company was held a short time ago in Montreal; W. McLea Walbank, the president, in the chair. The object for which the meeting was called, was to approve of the construction of the new fire-proof station on Chenneville street, now in course of construction, and of ratifying a loan of $75,000 which had been taken up by three of the Ottawa shareholders of the company. Both of these matters were agreed to. The following contracts were awarded: That for engines to the Westinghouse Co., of Pittsburg; for rotary converters to the Canada Electric Company, of Peterboro, and for boilers to Babcock & Wilson.

A patent has been granted to a resident of Vienna, Austria, Anton Othmar, on a composition for arc light carbons, consisting of finely ground wood charcoal or carbon from gas retorts, or both, mixed with finely-ground quartz and diamond dust. The mixture is made up into a dough by incorporating it with a solution of copper salt and with jellied salicylic acid the pencils being moulded from this in the ordinary way and afterwards burned, as usual. The proportion of ingredients by weight are: Carbon, 83 parts; quartz, 7 parts; diamond dust, 10 parts. To 20 parts of the thoroughly mixed powder are added about one quart of a concentrated aqueous solution of copper sulphate and one quart of jellied salicylic acid. The inventor claims that carbons made in this manner burn much more slowly than those in present use.

Mining Matters.

A winding-up order has been issued against the Eastern Townships Chrome Iron Mining and Milling Company.

Leopold Myer, representing a Belgian syndicate, has purchased from T. B. Caldwell, Lanark, Ont., the Calabogie iron mine, for $100,000, paying $10,000 down.

Another attempt will, it is said, be made to utilize the magnetic iron sand of Moise, Bersimis, and other points on the north shore of the St. Lawrence and Gulf.

The announcement has been made that thousands of tons of iron ore have been bought in Newfoundland by Philadelphia capitalists for shipment to that port, to be manufactured into steel.

It is said that the deposits of nickel ore near St. Stephen, N.B., will be thoroughly investigated at once by the English owners, and a perpendicular shaft is to be sunk to the depth of two hundred feet.

The compressor plant reported in our issue of July as being sold to the Rosa Marie Mines on the West Coast of Vancouver Island, was sold and built by the Canadian Rand Drill Co. instead of the Jenckes Machine Co., as reported.

The Graham-McKellar group of iron properties on the Atikokan range, consisting of 16 locations, containing 1,200 acres, and covering 4½ miles of the range, has been bonded to Ronald Hunter, representing American capitalists, for $350,000, for 18 months, so that the parties may test the properties. The sum of $10,000 was paid for this option.

The additional thirty stamps intended for the Dufferin mill at Salmon River, N.S., are in course of erection, the foundations and mortars being already in place. It will be some months yet before the entire complement of sixty stamps are working, as another compound Corliss engine is to be installed to provide the required power.

The Vancouver, B.C., Province, publishes a story to the effect that rich placer fields of gold have been discovered near the upper entrance to the Alberni Canal on the Pacific coast. The distance to that part of the country is about 150 miles by water, from Victoria. It is said that as high as $2 to the pan has been gotten by prospectors.

There have been discovered in the Lake Temagamingue district vast deposits of arsenical iron, carrying gold, which, it is reported, are the largest and richest deposits of this mineral in the world. The ore is in a solid body, it is said, over 1,020 feet long by 310 feet wide. It would take over three generations to take a layer 10 feet deep off the whole tract. The assays show over 47 per cent. of crude arsenic to the ton and $8.20 of gold.

The Foley gold mine in northwestern Ontario has been sold to the Canadian Mines Development Company, Ltd., of London. The Foley Mines Company treasury receives $50,000 cash, and $354,000 in stock, to be divided pro rata among the shareholders. The mine will be started up at once, and the 20 stamp mill will soon again be turning out bullion. The British company is capitalized for 300,000 shares of £1 each. Of these, 150,000 shares go to pay for the property; 75,000 shares, par value $375,000, will be retained unissued in the treasury for a working capital, or to acquire other properties. Still 75,000 more shares have been placed on the market at par in London.

The Ontario Bureau of Mines has arranged for a series of summer mining schools to be held at points in the mining districts of the province, including Parry Sound, Rat Portage and Mine Centre. At each of these places there will be a course of ten days' instruction by lectures and demonstrations by Professors Goodwin and Nicol of the School of Mining, Kingston. The classes will be free to miners, prospectors and others who may desire to take advantage of them. In addition to the regular classes, popular lectures are to be given by Professors Goodwin and Nicol on mining subjects, at other points in the mineral districts. The class of instruction has been already opened at Parry Sound, where there is great activity, stimulated by the recent copper discoveries. So far 72 students are enrolled and the average daily attendance is 55. Two sessions per day are held, each being of two or three hours' duration. Lectures have been given at Marmora, where the Delora gold mine is in splendid shape. Manager Kirkgaarde has improved the plant in many respects, and the stamp mill is showing good returns. The old Arsenic Works are being overhauled and will be in operation in a few weeks.

Marine News.

Two Yukon steamers, the "Nahleen" and "Louise," have been totally consumed by fire at Victoria. The total loss will reach $100,000.

The Richelieu & Ontario Navigation Co. has already filed up receipts in advance of last year, though the season was much later in opening.

From the opening of navigation to the end of July over five million bushels of grain were received at Depot Harbor for the Canada Atlantic Railway.

The Canadian Canoe Co., Peterborough, Ont., reports a very busy season, being still crowded with orders. During the past season in addition to the home trade, this company has shipped several consignments abroad to Great Britain and other countries.

A. T. Wood, M.P.; Wm. Southam, C. E. Doolittle, C. Wilcox, Wm. D. Long, and A. B. McKay, Hamilton, Ont., have applied for the incorporation of the Quebec, Hamilton & Fort William Navigation Company, Limited. The capital stock of the company is $1,000,000. The head office is to be in Hamilton.

Recently the Calvin Company's new steamer "India" had a trial run around the harbor. Her engines worked well, and she answered her steering gear to perfection. Her first trip was to Cleveland, Ohio, to load coal for Fort William, after which she went to Serpent River, Wis., to load iron ore for Deseronto, Ont.

The Red river, which was the principal artery of commerce in Manitoba in the early days, but which has been almost out of use since the advent of railways, is again to be used for traffic purposes. R. A. Lister & Co. have put a steamer on the river to gather up cream for their butter factory at Morris. This is probably the first attempt at utilizing the river for regular traffic purposes south of Winnipeg, since 1882.

The regulations made by the Ontario Government making it imperative that logs cut on Crown timber limits be manufactured in the province, has given the Ontario shipowners a share of the trade in carrying the lumber. The rafting of the logs to which the embargo applies from the Georgian Bay across to points in Michigan has now been stopped, and the Michigan lumbermen are compelled to have their logs sawn here. No vessels were necessary in towing the logs across except tugs, and under the United States coasting law, Canadian vessels could not afterwards help in carrying the manufactured lumber from one American port to another. One result is, that now Canadian vessels are conveying the sawn timber to the numerous ports on the American side.

Personal.

G. H. Garden, of the C.P.R. engineering staff, has gone to take charge of the double tracking of the line between Port Arthur and Winnipeg, a distance of 420 miles.

H. V. Short has been appointed manager of the machinists' tools and engineers' supplies department of the Aikenhead Hardware Co., in succession to A. W. Smith, whose portrait appears in another column of this issue of The Canadian Engineer.

L. B. Stewart, Registrar of the School of Practical Science, Toronto, has reached Dawson, in the Yukon district, where he purposes spending the vacation surveying. A letter posted by him at Dawson on the 3rd July was received by Mrs. Stewart in Orillia on the 25th.

A Canadian, A. W. McCrea, of Merrickville, Ont., was selected from among his class of fifty at the Massachusetts Institute of Technology to represent the architectural department at the closing class ceremonies. He has taken a position with the firm of Cariere & Hastings, prominent architects of New York.

C. A. Woolsey, recently appointed sales agent of the Royal Electric Co., was for some time with the Thompson-Houston Co., as expert, and upon the amalgamation of that company with the General Electric Co. remained with the concern as expert engineer and salesman, with headquarters at New York. Mr. Woolsey has had a wide and varied experience, embracing almost every phase of electrical engineering.

C. J. Pusey, president and manager of the Irondale, Bancroft and Ottawa Railway, died at Peterboro recently from an organic affection of the heart. Mr. Pusey was in railway work all his life. In 1866 he purchased the nucleus of the present I., B. & O. Railway, six miles of complete line, extending eastward from the junction with the Victoria branch of the G.T.R. His object was to extend the line to Brockville, with connections to Ottawa, to give an United States outlet to mining products and to extend the line westward and north to the Georgian Bay. His idea was the establishment of large smelting works in Hastings County. By his own almost entirely unaided exertions, Mr. Pusey secured Ontario and Dominion charters, and in the face of great difficulties finished the scheme and extended his railway eastward by ten-mile sections till now 47 miles are in operation, with five additional miles to be completed this fall. The line has a fairly paying traffic and is doing much in developing the lumber resources of the region it taps, promoting settlement and giving access to promising mining areas abounding in gold, silver, lead, iron, corundum, mica, etc.

Railway Matters.

The last relic of the first epoch of railway engineering in Canada is passing away this month in the form of the tubular bridge on the G.T.R. at St. Anne's. This old bridge, which spans the Ottawa near its junction with the St. Lawrence, is being removed, and a trussed bridge erected in its place. This old bridge is not only the last of the tubular bridges in Canada, but the last on this continent, and its removal is a historic event. The double tracking of the Grand Trunk between Toronto and Montreal is proceeding. A short section of two miles from Trenton to Murray Hill and one of three and a half miles from Sydney to a point east of Trenton, both of which are in progress now, will make the double track complete between the two cities, excepting only a strip of 30 miles running east from Scarboro Junction, on which, however, the traffic is not so heavy as on the rest of the route. A double track is also being made east of Montreal from St. Lambert to St. Bruno. Of the twelve big passenger engines, recently described in this journal, six are now on the service between Montreal and Toronto, and the new train equipments on this part of the Grand Trunk are spoken of in the highest terms by the travelling public.

RAILWAY SUBSIDIES.

The Minister of Railways has proposed the following resolutions: That it is expedient to authorize the Governor-in-Council to grant a subsidy of $3,200 per mile towards the construction of each of the undermentioned lines of railway (not exceeding in any case the number of miles hereinafter respectively stated), which shall not cost more on the average than $15,000 per mile, for the mileage subsidized, and towards the construction of each of the said lines of railway, not exceeding the mileage hereinafter stated, which shall cost more on the average than $15,000 per mile for the mileage subsidized, a further subsidy beyond the sum of said $3,200 per mile of 50 per cent. on so much of the average cost of mileage subsidized as shall be in excess of $15,000 per mile, such subsidy not exceeding on the whole the sum of $6,400 per mile.

Central Ontario Railway Company, for an extension from, at or near either Coe Hill or Rathbun Station on the company's railway, at or near Bancroft, not exceeding 21 miles, in lieu of the subsidy granted by 55-56 Victoria, chapter 2—Re-vote.

Great Northern Railway Company, for a railway between Montcalm and St. Tite Junction on the Lower Laurentine Railway, Quebec, not exceeding 53½ miles, and for a branch from their main line to Shawenegan Falls, Quebec, not exceeding 6½ miles, 53½ miles—Re-vote.

Phillipsburg Railway and Quarry Company, shortage in the extension of their railway from a point on the company's line at or near the end of the subsidized section to the Government Wharf at Phillipsburg, Que., not exceeding 6 6-100 miles—Re-vote.

Strathroy & Western Counties Railway, for a line from Strathroy, Ontario, via Adelaide and Arkona to either Forest, Thedford or Parkhill, not exceeding 24 miles, in lieu of subsidy granted by 57-58 Victoria, chapter 4, partly—Re-vote.

St. John Valley & Riviere du Loup Railway Company, from Fredericton to Woodstock, not exceeding 59 miles—Re-vote.

For a railway from Port Hawkesbury, on the Strait of Canso, Nova Scotia, to St. Peter's, not exceeding 30 miles—Re-vote.

For a railway from Windsor, N.S., to Truro, via Township of Clifton, not exceeding 58 miles—Re-vote.

For a railway from a point at or near Brockford Station, N.S., on the Intercolonial Railway, to Eastville, not exceeding 25 miles—Re-vote.

For a railway from Cross Creek Station, on the Canada Eastern Railway, to Stanley village, N.B., not exceeding six miles—Re-vote.

For a railway from the village of St. Remi to Stottsville,

or some point on the Delaware & Hudson (Grand Trunk), in the parish of St. Valentine, not exceeding 19 miles, of which 12 miles is a re-vote.

For a railway between Pontypool and Bobcaygeon, via Lindsay, Ont., not exceeding 40 miles, 32 miles re-vote.

Pontiac Pacific Junction Railway Company, for a railway from Aylmer to Hull, Que., in lieu of the subsidy granted by 60-61 Victoria, chapter 4, not exceeding nine miles.

Portage Du Fort and Bristol Branch Railway Company, for a branch line on the Pontiac Pacific Junction Railway, at or near the village of Quyon, towards the village of Portage Du Fort, Que., not exceeding 15 miles, in lieu of the subsidy granted by 60-61 Victoria, chapter 4—Re-vote.

Oxford Mountain Railway Company, for a branch from their railway from a point between Lawrenceville and Eastman, to Waterloo, not exceeding 13 miles; 4½ miles re-vote.

Atlantic and Lake Superior, from Coplin to Paspebiac, Que., not exceeding 30 miles.

United Counties, from St. Robert Junction to Sorel, 6½ miles, and from Mount Johnson to St. George station, 1 mile, not exceeding 7½ miles.

For a railway from a point on the Central Railway, County of Lunenburg, N.S., to Liverpool, via Caledonia, or to the village of Caledonia, via Liverpool, or for any part thereof, the whole distance not exceeding 62 miles—Re-vote.

For a railway from Indian Garden, Queen's County, N.S., to Sherbourne, a distance of 35 miles—Re-vote.

The subsidy which the Ontario and Rainy River Railway Company is entitled to receive, under chapter 4, 60-61 Victoria, shall be $6,400 per mile, for the 80 miles provided for in the said Act.

Bay of Quinte Railway Company, for such extension, not exceeding $3,200 per mile, for 10 miles, nor exceeding in the whole $32,000—Re-vote.

Quebec and Lake St. John Railway Company, for 12 miles, from end of their line at Deep Water, on the Chicoutimi branch, to Ha Ha Bay, in lieu of the subsidy granted by chapter 4, of 1894.

For a line of railway from Hawkesbury, Ont., to South Indian, not exceeding 35 miles.

For a railway from Sault Ste. Marie, Ont., towards Michipicoton river and harbor, and to main line of Canadian Pacific Railway, not exceeding 40 miles.

For a branch line from the main line of the Ottawa, Arnprior and Parry Sound Railway, to the town of Parry Sound, Ont., not exceeding five miles.

For a railway from the village of Haliburton, via the village of Whitney, towards the village of Mattawa, Ont., not exceeding 20 miles.

For the extension of the Tilsonburg, Lake Erie and Pacific Railway, from Tilsonburg to Ingersoll or Woodstock, Ont., not exceeding 28 miles.

To the South Shore Railway Company, from Sorel Junction, along the south shore of Lothiniere, Que., a distance not exceeding 82 miles.

Massawippi Valley Railway Company, for an extension to Stanstead Plain, Que., not exceeding 2½ miles.

For a railway from Port Hawesbury, on the Strait of Canso, to Caribou Cove, N.S., a distance of 10 miles.

For a railway from Fort Frances, Ont., westerly to a point at or near the mouth of Rainy River, a distance not exceeding 70 miles.

To the General Railway Company, of New Brunswick, for an extension from Newcastle coal fields to Gibson, N.B., not exceeding 30 miles.

Canadian Northern Railway Company, for a railway from a point on the present line of the Winnipeg Great Northern Railway, north of Swan River, to Prince Albert, N.W.T., not exceeding 100 miles.

For a railway from some point near Arthur Station to a point south of Moose Mountain, Manitoba, not exceeding 50 miles.

For a railway from Sunnybrae to County Harbor, and from a point at or near County Harbor cross roads to Guysboro, N.S., to make up deficiency in mileage between points mentioned, additional mileage not exceeding 15 miles.

For a railway from Port Clyde to Lockport, N.S., not exceeding 20 miles.

For a railway from a point on the Intercolonial Railway at or near Halifax to a point on the Central Railway in the County of Lunenburg, not exceeding 20 miles.

For a railway from Labelle, in the Province of Quebec, in a north-westerly direction to Nominingue via Notre Dame Del Annonciation, a distance not exceeding 22 miles.

For a railway from Owen Sound to Meaford, not exceeding 21 miles.

Ottawa and Gatineau Valley Railway Company, for their line of railway in and through the city of Hull, Que., not exceeding four miles.

Western Alberta Railway Company, from a point on the United States boundary west of Range 27, north-westerly towards Anthracite, in the district of Alberta, not exceeding 50 miles.

Edmonton, Yukon and Pacific Railway Company, from South Edmonton, N.W.T., to North Edmonton, and thence westerly towards the Yellow Head Pass, a distance not exceeding 50 miles.

Restigouche and Western Railway Company, in addition to the 20 miles granted, and in continuation towards the St. John river, a further distance, not exceeding 15 miles, and towards Campbellton, a distance of 12 miles in all, not exceeding 27 miles.

For a railway in extension of the St. Francis branch of the Temiscouata Railway, to the mouth of the St. Francis river, a distance not exceeding three miles.

Canada Eastern Railway Company, from Nelson, N.B., to connect with the main line into Chatham, 2¼ miles.

Bay of Quinte Railway Company, for an extension in a westerly direction from Deseronto for a distance not exceeding two miles; also for an extension from Tweed in a northerly direction not exceeding five miles, in all seven miles.

Ontario, Belmont and Northern Railway Company, for an extension from iron mines in a north-westerly direction a distance not exceeding five miles, and also for an extension railway southerly from the present southern terminus to the Central Ontario Junction of the Canadian Pacific Railway, a distance not exceeding two miles, but the last-mentioned aid for the said two miles of railway shall not be granted in case the Railway Committee of the Privy Council finds that adequate running powers on fair terms cannot be secured to the company over that portion of the line of the Central Ontario Railway between the present southerly end of the Ontario, Belmont and Northern Railway and the Canadian Pacific Railway Company's line at Central Ontario Junction.

For a line of railway from a point on the Pembroke Southern Railway, at or near Golden Lake, Ontario, towards a point on the Irondale, Bancroft and Ottawa Railway, at or near Bancroft, not exceeding 20 miles.

(To be continued).

WANTED—Young man familiar with installing and repairing electric recording meters. Give particulars of experience. Only hustlers and first-class penmen need apply. Advancement if satisfactory. Address "WATT," Canadian Engineer, Montreal.

WANTED—A First-class Mining Foreman, who has had experience in Galena, Zinc and Silver Mining. Send references and rate of wages expected to P. W. RESSEMAN, 31 Central Chambers, Ottawa, Ont.

FOR SALE

A good Water Power, 500 horse, situated one-half mile from railway, every facility for making siding to power. Address
J. D. THEUNISSON, Cookshire, Que.

Canoes & Boats

For Prospecting

All Kinds of pleasure Canoes and Boats

For THE CANADIAN ENGINEER.

REVOLUTION OF THE PRESENT RAILWAY SYSTEM BY THE ADVENT OF THE ELEVATED ELECTRIC RAILWAY.

BY A. DAVIS, CONSULTING ENGINEER, MONTREAL.

About sixty years ago England gave birth to the steam surface railway, and inaugurated the present system, and now it is about to inaugurate the railway of the future. England waits the proper time before adopting any new invention, and spending money uselessly. Her people will generally make sure of the new undertaking, and will then wait to see if anything better will turn up that can replace what is already in operation with lasting advantage, as they have done in the present case. They have waited sixty years for new developments in railway systems, but in reality there has been comparatively no change in the last fifty years, although it must be admitted that the speed has been increased on passenger trains during the past forty years about twenty miles per hour. The changes in themselves have not been elementary, but consist only in making the cars more comfortable for the traveling public. The weight and size of the railway rolling stock has been increased greatly for facility and economy in operating railways of America, but not so rapidly in England. In this fact the prudence of the English people again shows itself. They correctly think there is a limit, and have stopped increasing the weight of their rolling stock, and have turned their attention to how it would be best to meet the emergency which demands greater facilities and quicker means of transit, with more absolute safety.

Our American railway managers as yet see no limit, and they are increasing the size of the carrying capacity of their rolling stock. From ten to thirty-ton car engines are also increased in power and corresponding weight; all this with one idea in view, and that to reduce the cost of operation of their line. Of course, this looks well calculated to give the company the desired result. The main substance in this decision is the great saving of labor; in fact the managers will tell the directors of their companies that in place of two trains being required to move a given quantity of freight, one train with one staff will do the work, so that 50 per cent. is saved on engine drivers, firemen, conductors, and brakesmen, and 50 per cent. on locomotives. This is for freight trains only, as the number of passenger trains remains the same. When this report is made at a directors' meeting, there are smiles and happiness all round. They are also shown the great change made by steamship companies of replacing the small steamers with those of four times the carrying capacity. In this, no doubt, a great saving is obtained without so great an outlay. A large expensive steamship must be paid for to replace, say four of the smaller ones, but it cannot be compared with the change that follows in the railways increasing the carrying capacity of their rolling stock proportionately. The changing of the small steamers to the large ones means one steamer to each four, hence one crew, one set of officers, one set of engines and boilers, in fact, one complete ship at sea, one steamer berth at harbor, all in place of four. It is true that the crew will number a few more men than on a small steamer, and the consumption of coal is greater, but not nearly as much coal will be used as on four smaller ones. The risk of accidents at sea is lessened by 75 per cent., therefore the saving must be very great. Also, the steamship company does not lose the small steamers, as steamers of almost any size can be put into service at various classes of carrying on the sea, so that reduces the expense to a large extent, and the extra expense ends there.

Now let us see how differently the change affects the railway companies when the carrying capacity is proportionately changed. In place of one ship, thousands of new cars are required, and in place of one engine, hundreds of new locomotives are needed. This is not all. The very moment this new heavy rolling stock is ready to be put into operation, new and heavier rails, new and larger ties, and new and stronger bridges are required for the whole line, as well as new turntables for locomotives; the road-beds require additional ballast, and in many cases new engine-houses are needed. In the repairing shops additional machines to

take in the larger parts of the larger locomotives will be necessary; in fact the companies may look to the expense of a new railway, less the right of way and road-bed, to meet the change, all in addition to almost the total loss of the rolling stock, rails, bridges, etc., as all of it can only be scrapped at best, as when the change on a few of the trunk lines takes place, all other lines will have to follow or they could not compete, so that old rolling stock will be discarded, hence the great loss; so that when all the cost of this change has been correctly figured it will change the net receipts after the interest has been paid on many milions of outlay. Again, the maintenance of the new heavy rolling stock, and the wear and tear of the rails, bridges, road-bed, and rolling stock itself, will be much greater. The same number of bearings will have greater friction, hence a large increase of lubrication and wearing material. The road-bed and bridges will suffer in proportion; the extra friction, which will have to be applied to the wheels to stop these heavy trains, and to moderate their speed on down grades, and likewise on the pull-up grade—the extra adhesion required to the rails—all this will cause quicker destruction, and again the accidents.

While it is strange to say that the system of steam surface railways has been in existence about sixty years, there have been comparatively no improvements outside of the enlarging of the cars and locomotives, and making them stronger and more comfortable for travellers, and indeed following the extravagant luxury of hotels, etc. Outside of this the system is comparatively the same. The speed of passenger trains has been increased about twenty miles per hour in forty years. The cost of transit for persons and freight remains about the same on the all around average. Regarding accidents: While various devices have been applied, the only one which has been of any consequence in minimizing the number of accidents to the employees is the automatic coupler, which is still far from perfection. The number of accidents on railways of all kinds and under all circumstances have been continually on the increase, and the cause of this is that the competition of railways has become greater as new railways have been built continually, and railway managers have had but one object in view, and that is, cheapness of operation of their line; so that cheap material and construction has been used; anything that would call for a little additional expense for the minimizing of accidents not being entertained. The crowding of railways into large cities has become so congested that accidents are almost of daily occurrence. Now, what is to be done to insure safety of travel on railways—quicker transit?

The elevated electrical railway is no doubt the rail way of the future, and as England gave birth to the first system of steam railways, that country is about to give birth to the coming system. They are about to build an elevated railway in a district full of railways, that is, between Liverpool and Manchester. This proves that they feel sure that the new mode of transit will and must be this system, that will gradually take the place of the surface railways, both for passengers and express freight. First, there is the surety that an elevated railway can be made so as to insure positive safety from all accidents whatever, running at 100 miles per hour, or more, because being elevated no contact with moving or other objects on the ground surface will be liable, no accidents from floods or washouts, landslides, or misplaced switches will occur, nor from broken wheels or rails, or any kind of collisions resulting from the mal-intent of anyone putting anything on the track. In the case of trains following each other, the connections would be cut from the power of the following train by the operations of the first train, which might be stopped from any unforeseen emergency; so that the following train would have no propelling power in case of the necessity to stop the first train, and the electric signal would automatically strike the bell on the train that followed. As to falling off the track, that would be prevented by a gab grip that would follow the T of the top cord of the truss, so that it would be impossible for the wheels to mount the rail or get the body of the car lower than the top cord of the girder, only four inches distant. The side of the car is also protected by the sides of the girders, which have a flat, smooth plate running on both sides, which would come in contact with rollers fitted on the sides of each car. There would be no snow to ever block the line or cause any expense or accidents; no grades of any consequence, so that the uniform speed would be constant; no short curves to create danger or extra friction, the track would always be uniform and the cars would always run very smoothly; no dust and cinders or grit to cut up bearings and the machinery, thus all axles could be made to run smoothly in ball bearings with comparatively little lubricant, and the cars would be free from smoke and dirt of any kind.

One can fancy the comfort to travel in cars that are perfectly safe, running smoothly, with good and clean ventilation, also the enjoyment of looking over all the surrounding country as a good panorama. The electric single rail projected by F. B. Behr, for the elevated railway to be built from Liverpool to Manchester, is not the style of railway that can be practically successful. With the single rail system, the one wheel would not be sufficient to attain a very high rate of speed, as the one rail system would cause the wheels to slip, the extra friction would be a great detriment, which would be caused by oscillation that must take place from the uneven loading of cars, wind, etc. While the new system invented is perfectly free from any interference from the above causes, and the railway itself can be built much cheaper, lighter and safer, the cars remain the same type as the surface cars are at present. Of course the cost of building an elevated railway would be greater on the first outlay than a surface railway, on account of the height it must be made at some places, such as crossing rivers, towns, etc. This will require pillars or piers to be made very heavy and strong for perfect safety. But on the other hand the mileage can be reduced on the average at least 25 to 30 per cent. There would be comparatively no right of way to pay for, as only the pillars will take up any valuable space in the country, and very little anywhere. No embankments, no ditches, water culverts, stone or brick arches for roadways, no tunnels to be cut through mountains, no fences, no men to guard level crossings or on the track, no accidents to trains on crossings, and no expense caused by the killing of people or beasts on crossings, and no ballast required, which with its maintenance is a very large item.

After all the above items and the constant maintenance of the same is carefully summed up, it will go

very largely to make up the difference in first cost. Then comes the difference in cost of operation of the two systems. One, the electric elevated, comparatively no dead weight of locomotives, and only the motor car, and less than half the dead weight of the cars to be hauled over the line; the staff of engine drivers and firemen with all the assisting staff at engine houses reduced; no haulage of coal and water over the line; no water stations, water pipes, and water pumping engines; coal stations and the staff—all will be reduced to three power stations per 100 miles, where its boilers, engines, and machinery are stationary; no cost for its haulage; also the engines, as already stated, use up the line with their heavy weight; all the heavy gear wears away much faster. No damage from fire caused from sparks of locomotives, and no more burning up of trains and passengers when trains are run off the track and down embankments or in collisions. Also by removing the passenger trains from the surface railways will give much more facilities to freight trains, which will also prevent many accidents and delay to the freight in transit. Now this is only a question of the first outlay, which cannot help but double itself in a short time, and be a blessing to the human race in its advance with the commercial progress of each year. I am quite sure that my system of elevated railway will accomplish all I claim here, and even more when all the details are fully considered.

Now, as to its possibility of revenue sufficient to warrant the outlay. Say that such a line should be built from New York to Chicago. The present time consumed to make that run is about 35 hours, while the time would be only 7 hours by the elevated, the distance being reduced to 700 miles, and the train running at 100 miles an hour, would be 7 hours in place of 35 hours, or 14 hours in place of 70 for the round trip; outside of the person arriving by the elevated perfectly rested and ready for business, in place of requiring six or eight hours to rest after one has travelled to Chicago by the present system. As to number of passengers, they could afford to go a distance of 300 or 400 miles, to start for Chicago from New York. Say passengers from Quebec, Montreal, or Boston, could reach New York in one night and take the elevated, they would still make the journey in about half of the present time, and the same in the vicinity of Chicago. An elevated line built now between these two points would be only a beginning of the new system, which would not only be a great rate of interest on the outlay, but a general benefit to the travelling human race.

PROPOSED IMPROVEMENT AT LACHINE RAPIDS WORKS.

The Lachine Rapids Hydraulic & Land Company is undertaking a considerable amount of work this year, at the Lachine Rapids, the experience of the past two winters having exhibited the action of the water and ice both at the head and tail races. Last winter, for instance, the water in the tail race was abnormally nigh, higher, it is said, than it has been for thirty or forty years, and while the head race was not materially affected, so far as the supply of water was concerned in the river, yet the ice entered the intake and would not permit of sufficient quantity of water entering, without drawing down, so that they had to meet the worst conditions possible, namely, the highest back water and low head water inside the intake. Various schemes have from time to time been suggested for preventing the entrance of this ice into the head race, principally by means of large and deep booms.

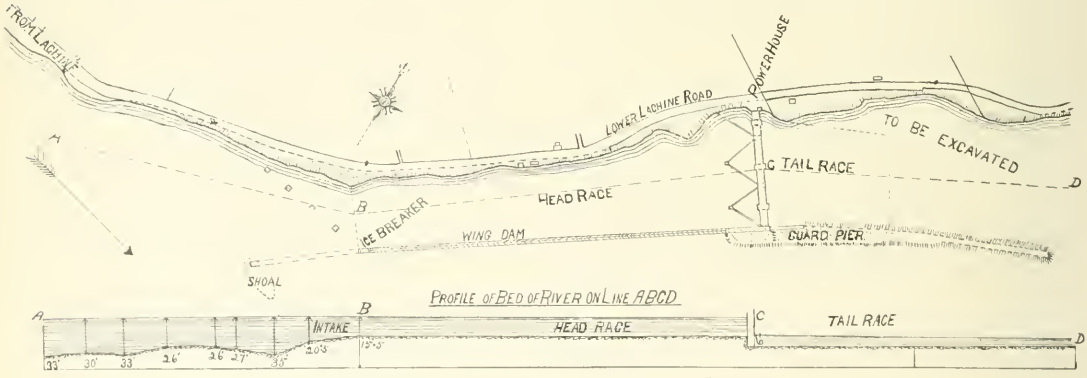
W. McLea Walbank, the original promoter of the company, and one of its engineers, was decidedly against this principle, inasmuch as he contended it would be almost impossible to construct a boom that could be held there, and in addition to which, the current is so strong that even a deep boom would be of little or no use.

After the ice went out of the river this spring, Mr. Walbank had his assistants carefully sound the river above the intake, and submitted to the directors a scheme for the improvement of the works and suggested consultation with outside engineers. The result of the soundings taken in the river showed that there was a deep channel connecting with the main channels of the river at McDonald's Point, as shown on the accompanying plan. This deep channel continued down to almost in front of ice breaker, where the water was turned almost at right angles into the river. The result was that the current had a tendency to draw the ice from the river opposite McDonald's Point, following the deep channel and discharging between the shoal and ice breaker, and naturally depositing ice at the mouth of the intake, which gradually filled up and impeded the flow of water. The channel between this shoal and the ice breaker is somewhat over 20 feet deep. The plan proposed by Mr. Walbank was as follows: Raise the existing wing dam the level of the water in the head race during the month of December, so that there would be absolutely no water running over during winter; also extending the wing dam the same level about 1,000 feet further up the river. The result of this would be to make the intake, in place of 525 feet wide, nearly 2,000 feet wide, and the water in place of being 12 feet deep, would be between 30 and 40 feet deep. The current at present there would be destroyed and the river freeze over. The main direction of the river current would then be at an angle with the head race, rather than leading into it, as at present. For the improvement of the tail race, he suggested the raising of the guard pier about 4 feet, and the extending the same down stream, a distance of about 1,000 feet, and excavating of a deep channel between the guard pier and main shore, and removing the shoals. The object of the extension of the pier was to deflect the ice into the stream. The river below the rapids freezes over in some winters, and forms natural dams in the river itself, which raises the water very considerably, last winter coming one foot over the present guard pier. The object of raising it was to prevent a re-occurrence of this and to allow the tail water to take the discharge of the wheels only, without being influenced by the water in the river, except the natural backing up which occurs every year to a greater or less extent, and which is allowed for in the original plans. In addition to the foregoing, a glance pier from McDonald's Point, running completely down stream, was suggested.

T. C. Keefer, an engineer of very high standing in hydraulic matters, and well-known to our readers, was consulted by the company, and he has reported to the Lachine Rapids Company, endorsing the scheme

here outlined. He says, in his report: "The closing of this cross river channel will not only send the river current and its ice above and outside of, instead of below and inside the shoal, and move it at least one thousand feet from the comparatively narrow and shallow entrance to your head race, but it will destroy the current leading to its mouth. It will move the entrance from its present position to a line opposite the head of the shoal, where the water is both wider and deeper, so that it will be three times greater in area than at present. Above McDonald's Point, the shore line trends to the right, and its course, if produced down stream, would strike the shoal about where the extended wing dam would have its ice breaker. When this extension is made, the shore line of river current, instead of rounding McDonald's Point and flowing in shore, will flow nearly in a straight line toward the new ice breaker and outside the shoal. Your entrance basin, instead of being five hundred feet wide and twelve feet deep, will be about four times as wide and three times as deep. Its current will, even when all your wheels are going, have little attraction for the frazil compared with that of the St. Lawrence, where it has a fall of twelve inches per mile. At present you have no entrance basin, but feed the bordage ice. The extension of the wing dam will have the effect of raising the level of the head race (thus increasing the water power), but to what extent it is impossible to say, probably not exceeding six inches. The level of your wing dam should be such that no water can flow over it when ice is running in the river, especially frazil, because the draught caused by this overflow might exceed that caused by your wheels and bring in too much ice. When the cross river channel is closed, I do not think there would be any tendency of 'field' ice to enter the new basin for reason stated above, and then the level of the wing dam could be governed by the frazil level, as that will be after the extension."

Mr. Keefer further endorses a separation of the tail race from the river and the deepening of its channel, but was of opinion that the glance pier was unnecessary. The company has decided to immediately carry out these works, and the contract has been awarded to W. J. Poupore, M.P., Ottawa, as mentioned in the last issue of the Canadian Engineer, and whose firm are now making good progress in the work, the contract calling for its completion by December 1st. In addition to the foregoing, the Lachine Rapids Co. will protect its



Improvements in Lachine Rapids and Hydraulic Company.

direct from one of the deep channels of the river which brings its frazil to your doors, but with the proposed extension you will have a deep basin covering over two acres of surface, which will freeze over nearly to the line between McDonald's Point and the shoal on which your new ice breaker will be planted. This bordage ice on its river edge will be thickened by wind and wave, and act as a boom to exclude passing frazil. It will not entirely exclude it, for when the river above is covered at its wider part, and its ice is crowded into the narrower width, as it approaches the rapids the frazil will flow deeper and some of it will be forced under the bordage ice and out of the influence of the river current, when it immediately rises to the under side of the bordage, is frozen to it and thus thickens the ice boom. When the full draught of all your wheels is in force, some of the frazil elbowed out of the river may descend farther down, but will be arrested by its friction against the surface ice and laid up for the winter in the new basin before it can reach your head race. This ice boom will probably take a curved form chiefly toward the lower end, and more frazil be forced under on the side toward the wing dam than near McDonald's Point, leaving an inshore unobstructed channel under patrons by installing an auxiliary steam plant, which will place the works beyond any question of being able to supply their demands.

CANADIAN WATER POWER AND ITS ELECTRICAL PRODUCT IN RELATION TO THE UNDEVELOPED RESOURCES OF THE DOMINION.*

(Concluded from last issue).

In order to present more fully the recently enhanced value of our Canadian water power, some reference is necessary to certain properties of electricity, the power which has happily been described as "the most romantic form of energy," by Wm. Henry Preece, C.B.F.R.S., in his recent address as president of the Institution of Civil Engineers. Inasmuch as the cost of production of electrical energy depends upon continuity of output, water power must be the ideal one for this purpose, at least until some cheaper power is discovered. In some places where steam is now used for electric light, other industries have been added to secure the more continuous use of the power in daylight hours. The only quality in which any deficiency has been exhibited by electricity is for lighthouse purposes,

*Presidential Address read before the Society, May 23rd, 1899, by Thos. C Keefer, C.M.G., President of the Royal Society of Canada

a lesser power of penetration in fogs, in which respect it is inferior to oil or gas; but even this has in the present year been more than compensated for by the successful application of "wireless telegraphy," by which, in any weather, communication between the ship and the shore can be established. The shores of the St. Lawrence from the Atlantic to the lakes are lined with water power which can be used to light, in fair, or protect, in foul weather, the passing vessel; to ring the bell or blow the horn. When water is applied for light and power purposes, its economy is always the important factor; but it is chiefly to its value for electro-chemical industries that Canada will look to reap the greatest benefits, because in these it is not merely a question of competition of power producers, but one in which intense electricity has the monopoly, and in the case of some of them, as in the production of aluminium, calcium carbide, carborundum, etc., their existence depends upon ample supplies of an intense electric current, for the generation of which abundant and cheap water power is indispensable.

Touching electro metallurgical processes, Mr. Preece says: "Every electrolyte requires a certain voltage to overcome the affinity between its atoms, and then the mass decomposed, per minute or per hour, depends solely upon the current passing. The process is a cheap one and has become general. Three electrical h.p., continuously applied, deposits 10 lbs. of pure copper every hour, from copper sulphates, at the cost of one penny. All the copper used for telegraphy is thus obtained. Zinc in a very pure form is extracted, electrolytically, from chloride of zinc produced from zinc blende, in large quantities. Caustic soda and chlorine are produced by similar means from common salt. The passage of electricity through certain gases is accompanied by their dissociation, and by the generation of intense heat. Hence the arc furnace. Aluminium is thus obtained from cryolite and bauxite. Phosphate is also separated from apatite and other mineral phosphates. Calcium carbide, obtained in the same way, is becoming an important industry. Electrical energy can be generated on a coal field, where coal, of good calorific value, is raised at a cost of three shillings per ton, cheaper than by a water fall, even at Niagara."

Eastern and Western Canadian coal fields are separated by thousands of miles, but water power is abundant throughout nearly all this coalless region. Our Western coal fields are vast and their market at present limited. If coal can be raised cheaply enough and the raw material for the work be discovered in the neighborhood, they may give rise to electro-chemical and electro-metallurgical industries without the intervention of water power. The commercial production of calcic carbide (acetylene gas) by electrolysis, is the discovery of T. L. Wilson (a grandson of the late Hon. J. M. Wilson, of Saltfleet, Ontario), who has established works on the water powers of the Welland Canal and has shipped this product all round the world. The electric production, commercially, of caustic soda and chlorine, is under the patent of Ernest A. Lesueur, son of the Secretary of the General Post Office Department, Ottawa. This manufacture is now being carried on by a Boston company at a New England water power.

There is another field nearly as widespread as our water power in which electricity is destined to play a most important role, and this is mining, which is now spreading over the Dominion with the same rapidity as the utilization of our forests for pulp and paper purposes. Over this area minerals have been discovered and in many cases tested and successfully worked, and from recent results we appear to be on the threshold of remarkable developments in this direction, especially as so small a portion of so great an area has been prospected sufficiently for mining purposes. For power purposes alone, electricity is invaluable in mines, and its multifarious uses (as enumerated by Mr. Preece) are "for moving trams and for working hoists; it lights up and ventilates the galleries, and, by pumping, keeps them free from water. It operates the drills, picks, stamps, crushers, compressors, and all kinds of machinery. The modern type of induction motor, having neither brushes nor sliding contacts, is free from sparks and free from dust. Electric energy is safe, clean, convenient, cheap, and produces neither refuse nor side products." The Canadian mining districts are well supplied with water power, and all the wonderful effects of electricity are available for us upon a larger and more economical scale than elsewhere. In connection with this abundance of water power, and from the fact that a large proportion is at present situated remote from present railways and present settlements, the question of profitable limit of electrical transmission is most important—if indeed, it be now possible to put a limit on anything connected with electricity, with or without the aid of a wire. If, as reported, Lord Kelvin has placed the profitable limit at 300 miles, this is sufficient to utilize the greater part of the water power upon the two watersheds north of the St. Lawrence river. Professor Elihu Thomson says: "Up to the present time it was practicable to transmit high pressure currents a distance of 83 miles, using a pressure of 50,000 volts. If a voltage higher than that were used, the electricity would escape from the wires into the air in the form of small luminous blue flames." As showing how far we are yet behind nature, Professor Thomson says the estimated voltage from a lightning discharge ranges from twenty to fifty million volts. Wherever the raw material for electro-chemical, electro-metallurgical, or other industries, affords sufficient inducement, and the water power is at hand, the forest will be penetrated much more rapidly than heretofore, and settlements advanced in new directions. What can be done in this direction is best illustrated by the development of a single industry in the wilds of Minnesota, north of Lake Superior, and adjoining Canadian territory. Over four hundred miles of standard gauge railways have been built, through what was a trackless wilderness in 1885, to reach iron ore beds, the ore from which is shipped to Lake Erie and thence again railroaded 200 miles into Pennsylvania. This one business has, in mines, railways, docks and fleets of steamers, required an investment of $250,000,000, and has led to as low a rate, by water, as 1 cent per bushel for wheat between Chicago and Buffalo, and 20 cents per ton for coal from Lake Erie to Duluth, nearly 1,000 miles. One-half of the charcoal iron, and more than half of the pig iron made in the United States, is smelted from Lake Superior ore.

The substitution of electricity for steam as the motive power for railways on many roads is regarded as inevitable sooner or later. It has already taken place

as regards suburban railways, notably in the case of the Charlevoix road and Hull and Aylmer railway, where water is doing the work which has heretofore been done by coal. The chief obstacles to an early change on the larger roads are the hundreds of millions invested in locomotives, and the very large outlay required to equip existing steam roads with the electric system. The principal inducement would be the passenger service, owing to the increased speed possible—it being confidently stated that, with electricity, a speed considerably over one hundred miles per hour could be attained. Moreover, there would be the entire abolition of the poisonous smoke which drops upon the Pullman in preference to any coach ahead of it. While the conversion of trunk lines would be attended with a cost which is for the present prohibitory, this objection does not apply to new lines which may be worked independently, or in connection with electric ones. When the time arrives for such railways, water power will have a field of usefulness of which we can at present form little conception. Water wheels and wires would displace the coal docks, the coal laden vessels, the huge coal yards, and the trains required for distributing their contents over hundreds of miles of lines. An interior line connecting Lake St. John, on the Saguenay, with Lake Temiscamingue, on the Ottawa, which could ultimately be extended, via Missanabi, Nepigon, and Lac Seul to the Saskatchewan, would be a colonization road, removed from the frontier—one which could be worked possibly altogether by water power, and would open a virgin tract in which electro-chemical and electro-metallurgical industries might arise, as well as those connected with the products of the forests and the mine.

The more extended use of our water power, in the immediate future, for manufacturing and mining purposes, especially for the electro-chemical and metallurgical productions, naturally leads to the consideration of the character of the output, especially with regard to markets, and transportation problems generally. Transportation, next to production, is the most important commercial question to a country of vast distances and low-priced products, affording great tonnage, such as we produce; and for which we have expended hundreds of millions in canals and railways, harbors, light-houses and steamers, a sum disproportioned to our realized wealth, as it certainly is to our population. But, *"noblesse oblige,"* we possess a vast estate, are compelled to develop it—and await results. The question of transportation determines, to a great extent, the existence, or otherwise, of a possible industry, and enhances or diminishes the value of every article of export just in proportion to its efficiency and economy. On the other hand, where transportation is necessarily expensive, cheap production may maintain an industry—and here is where our abundant water power may come in. The geographical position of Canada in relation to the commercial centre of gravity of the North American continent is at least noteworthy. This centre is very near Lake Erie. From the western end of this lake the water route to the Atlantic at the Straits of Belle Isle follows the general direction of a great circle which cuts the commercial heart of Europe, and is therefore upon the shortest route, or "air line." Our two peninsulas, Sarnia-Detroit and Sault Ste Marie, which are the railway gates of the lake region, afford the most direct routes to the Atlantic for all the North-Western States, and are traversed by the trunk lines of railway. From Lake Erie water communication on the largest scale extends through Lake Huron to the extremities of Lakes Michigan and Superior. One-third of the population of the United States are dependent upon the Great Lakes, largely as to exports and imports, and wholly as to rates—which are fixed by the water for the rail routes. One-half of the population of the United States is found within a radius of 400 miles from Cleveland, a Lake Erie port claimed to be second only to the Clyde, as a shipbuilding one, and also the largest iron ore market in the world. The paper and pulp industry, as well as some of the electro-chemical and metallurgical ones (to the present list of which many additions may be made), are distinguished by the large tonnage produced, the output of several pulp mills exceeding one hundred tons per day. For this the St. Lawrence is the natural route for exportation, and to it this heavy tonnage is of the greatest importance as a means of attracting "tramps," as well as liners during the open season. Increase of sea tonnage into the St. Lawrence is essential to our inland commerce; by it only can sufficient west-bound freights be secured to attract a proper share of the commerce of the lakes, after all has been done to give to the latter quick despatch at Montreal or Quebec. There is probably no place in the world where inland transportation is carried on with greater expedition and economy than in the valley of the St. Lawrence. This is due to the character of the inland navigation, unequalled elsewhere, and to the influence which this exerts upon the railways competing with it; and also, because the valley of the St. Lawrence is not only the greatest highway for agricultural products, but of mineral ones, as well as of the products of the forest and the fisheries. More than half of the iron ore produced in the United States is mined around Lake Superior. Into this lake an increasing number of railways are pouring the produce of the vast wheat fields between it and the Rocky Mountains, and thus placing this grain within a thousand miles of Montreal, which is the nearest seaport, by hundreds of miles, and the only one which can be reached by vessels capable of navigating the lakes. Wheat grown in the foot hills of the Canadian Rockies has already reached Lake Superior by an all rail haul of 1,500 miles, a distance considered prohibitory in the early days of railways, as one which would absorb the whole value in the cost of carriage. The lateness of harvest in our North-West, and the early closing of navigation in the St. Lawrence, will soon over tax all our means of transport, both water and rail, during the interval between September and December. The Welland and St. Lawrence canals and the portage railways between Montreal and Lake Huron constitute the Canadian routes, and much, which cannot arrive by water in time for export, will be stored up at nearest lake ports for winter railway carriage to tide water warehouses on the St. Lawrence, for export at Atlantic ports—or for conversion into flour at Ontario and Quebec water powers. This accumulating tonnage from our Western plains and our Eastern forests must call for a proportionate extension of export facilities which should attract tonnage to the St. Lawrence. Already Montreal has eighteen regular lines of

steamers to transatlantic ports, exclusive of tramps. New York alone of the Atlantic ports exceeds this in number. Montreal has five regular lines to Liverpool and the same number to London, two lines to Glasgow, and two to Hamburg, and one each to Bristol, Manchester, Belfast and Antwerp. Baltimore has twelve regular lines of steamships to Europe, Boston nine, and Philadelphia eight. No doubt all these Atlantic lines exceed Montreal in number and tonnage of vessels, as well as in cargo carried. They have twelve months' navigation against seven for the St. Lawrence. The real significance of Montreal's eighteen regular lines of steamships is the demonstration that, in spite of climatic drawbacks, or inferiority in other respects, the St. Lawrence is the route towards which northern exports will gravitate during its open season.

PORTLAND TERMINUS OF THE GRAND TRUNK.

From Chicago on the west, to Portland on the east, change and improvement everywhere meet the eye of the traveller on the Grand Trunk Railway System. In all these changes nothing has been done for mere display or whim, but in every case money has been spent to give increased comfort and safety to passengers or to afford increased facilities for transportation of freight. An instance of the latter may be cited at Portland, where every provision is being made for the winter traffic, which the company will need to provide for at this terminus. Nature has marked out Portland as one of the great sea-ports of the United States in the future. Possessing a wide and deep harbor, well protected from storms by its archipelago of rock-ribbed islands across Casco Bay, of which Portland Bay is an arm, it is not only a safe winter port, but is so guarded by islands and capes as to be easily made a station of immense strength in time of war. Along this harbor the Grand Trunk owns a sea front of nearly a mile, and during the past two years the present management, foreseeing the needs of the sea-borne traffic of the port, have prepared to provide what the steamship companies are even now demanding, for arrangements are concluded which will make Portland the winter port of call of steamship lines, enough to give it practically a daily service to Europe. These contracts include a weekly boat each by the Allan and Dominion lines to Liverpool, a weekly boat to London direct by the Thompson line, fortnightly boats to Glasgow by the Allan and Donaldson lines each, fortnightly boats to Bristol by the Elder-Dempster line, to Hamburg by the Hamburg-American line, while there are reports of a fortnightly service to Antwerp by the Leyland line, and to Manchester by the Manchester line, though the last two proposals have not yet taken shape. To meet this traffic, which will be inaugurated in November, the Grand Trunk recently joined hands with some Portland capitalists in building a second grain elevator, the new one having a capacity of a million bushels, and being provided with three conveyors running direct to their own wharves, so that three or more steamers can take in grain at the same time. Ten cars can unload grain at one time in this elevator, which is provided with all the latest machinery for quick work, being able to deliver 30,000 bushels per hour. While the grain trade has been well looked to, other merchandise is amply provided for by four new freight sheds, each about 500 feet long and 100 feet to 120 feet wide. This gives six sheds alongside of which tracks are laid, and from which seven or eight ships can load at a time. In fact, ten vessels have been loading or discharging cargo at a time at the G.T.R. wharves, which can accommodate vessels of 500 feet length. There are also two coal wharves owned by the company, having ample capacity for present needs. Last year new tracks were laid in the company's yards to accommodate 1,500 cars, and this has been followed by the erection of new stock yards to accommodate the growing export cattle trade. The city of Portland, which has now a population of about 60,000, including the suburbs of Deering and South Portland, and which has an active board of trade, with a membership of over 300, appears to be fully awake to its opportunities. Its suburbs and the islands of Casco Bay are every year being resorted to more by Canadians, who always meet with a hearty welcome from the hospitable people of the Maine coast, and who find in the temperate climate and bracing sea breezes of this region an ideal summer resort.

THE CEMENT INDUSTRY.

The great increase in the production of Portland cement in Canada is causing considerable remark among those interested in engineering and the building trades. There does not appear to be a corresponding expansion in the business of the producers of the natural rock or hydraulic cements, and these latter complain that there is a prejudice growing up which is against them, and in favor of Portland cement makers.

The peculiar qualities of Portland cement, as distinguished from the natural or rock cements, are: A very much higher strength at early dates; greater uniformity in manufacture, due to the constituents being brought together artificially and therefore being controlled with ease. It can be laid in frosty, even winter weather, with safety; it will stand wear of pavements, etc.

The characteristics of natural or rock cements, which commend them to use, are: Their continually increasing strength, by which in time they are nearly equal to Portlands; safeness, as they are not over-limed; cheapness, near point of manufacture, where early strength or frost proofness are not requisite, and where concretes are not to be immersed in water for several months.

THAT "COMPRESSED AIR" FIZZLE.

Readers of The Canadian Engineer will remember our discussion on some of the auto-car schemes exploited in the United States, and particularly the Croker-Leiter scheme, relating to compressed air auto-trucks. Complete verification of our prophecies is to hand, in the form of an announcement that all the compressed air companies and affiliated concerns—nominally capitalized at about forty millions—are all to be merged into one central corporation, with H. Payne Whitney, son of William C. Whitney, as president of the new company, which will have a nominal capital of one hundred millions. Does this mean that we are to see the auto-trucks by hundreds doing work in our streets? Not at all; for, as the Cycle Age well says, "Nothing has as yet transpired in the way of inventions or tests that would make compressed air appear as

available for ordinary motor vehicles. The compressed-air motor is chiefly adapted for street railway power and for heavy freighting over very short routes." But the compressed air exploiters started in to revolutionize all traffic in the big cities, and cartage companies and all haulage vans were to be done away with. Is there nothing left, then, for the compressed air magnates to exploit? Yes; electricity! It is soberly stated that "the American rights, under the Krieger electric patents, are reported to have been purchased by them, and they are known to be pursuing further investigations into motive powers." This statement is corroborated by the fact that the word "air" has been dropped from the title of the new company, which is "The International Power Company." The Horseless Age remarks: "Putting two and two together, therefore, it looks as if the sceptics were right, and we should not be afflicted with these barbarous 'auto-trucks' after all. Perhaps when the company really gets down to business we shall have good, common, everyday motor trucks propelled by steam, gasolene, kerosene, or anything but compressed air." Now we will be prepared for the collapse of the Whitney-Elkins-Widener windbag.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS TENTH ANNUAL CONVENTION.

Berlin, Ont., had the honor of entertaining the members of the C.A.S.E. for their tenth annual convention, and she proved a worthy hostess. The convention opened on the 15th August, and ended with a banquet on the evening of the 17th. The delegates, who were accompanied by their wives, made the Brunswick Hotel their headquarters. The executive and the balance of the delegates were assigned to the American House, and the banquet took place in the hall of the Walper House. The convention held their business meetings in the Christadelphian Hall.

Tenth Annual Convention Canadian Association Stationary Engineers

It was nearly noon on the 15th when President Bro. W. F. Chapman, in the chair, supported by Vice Pres. Bro. R. C. Pettigrew, opened the session with the following opening charge from the C.A.S.E. ritual: "Brothers—It is my duty to rule with justice, promptness and forbearance, and it is your duty to make our meetings entertaining and instructive, avoiding all useless discussions and personalities, upholding your obligations by using toward each other brotherly love and kindness. Thus securing the great object for which we are organized, that of meeting together socially for mutual improvement and discussing the best methods of managing the world's greatest motor, steam, and its appliance to power. I hope each brother will be decorous and attentive to the business of the evening. I now declare this association open for its legal business."

The following committees were selected by the president, the first named in each case being chairman:

Committee on Credentials—Bros. Edkins, Marr and Turkington.

Committee on Finance—Bros. Webb, Wickens and Pettigrew.

Committee on Mileage—Bros. Bain, Ironsides and Jamieson.

Good of the Order—Bros. Dixon, Wickens, Oelschlager, Moseley.

The following answered the roll call: Executive—Bro. W. F. Chapman, president; Bro. R. C. Pettigrew, vice-president; Bro. G. C. Mooring, treasurer and acting secretary; Bro. W. Bear, conductor; Bro. J. Wendell, door-keeper. The delegates from branch associations were: A. E. Edkins, J. D. Moseley, J. W. Marr, W. J. Webb, J. G. Bain, of Toronto No. 1; John M. Dixon, Toronto No. 18; Jos. Ironsides, Hamilton No. 2; J. Ogle, J. Forsyth, Brantford, No. 4; W. Jamieson, Dresden No. 8; W. Oelschlager, Berlin No. 9; R. Turkington, Brockville No. 15; F. A. Pflug, Waterloo No. 17. Other members present were, A. M. Wickens, E. J. Philip, J. G. Bain, Jas. Bannan, of Toronto; R. W. Greene, Guelph; Nathan Uttley, Waterloo; W. Liedt, J. Schneider, G. Steinmetz, W. Oelschlager, of Berlin; Jos. H. Walker, of Kincardine. Among the visitors present at the meetings were T. J. Halsey, of the Fairbanks Co. of Montreal, and his samples of valves, asbestos-packed blow-off cocks and asbestos ring gate valves, interested the members very much. W. V. Uttley, of Berlin News-Record, was unwearying in his attendance, and coming of an engineering family took an active interest in the meeting.

Welcome to Visiting Delegates by President Oelschlager, C.A.S.E., No. 9.

On behalf of the Berlin Association No. 9, I have great pleasure in extending to you, Mr. President, and delegates of the Canadian Association of Stationary Engineers, a hearty welcome to our town, on this the 10th annual convention. The growth of the association here has been slow but sure. The members of the Berlin branch, realizing the benefit of the meetings, are good in attendance. In conclusion we welcome you collectively and individually, and trust that your stay in this German city will be most pleasant and profitable.

Annual Address of President Chapman.

Brethren—I have the honor to welcome you to this our tenth annual convention. I am aware that in selecting you as delegates, our various branches have sent their best men. Consequently, I am confident that your deliberations will result in the advancement of our organization, and that in dealing with the various subjects brought before you, the one and only aim sought shall be the greater good of the C.A.S.E. I am sure that naught but good will shall prevail, indeed, such is one of

the cardinal principles of our order. I need not ask for your hearty support, as this has always been given to the occupant of the chair. We have not increased the membership during the past year, only one new association organized, and very few new members added to replace those who withdraw and those taken by death. But brethren, I have the pleasure of saying that we have received into the C.A.S.E., out in Calgary, a lot of energetic members, that in the near future will have their subordinate lodge second to none in our fair Dominion. I have also in my possession a letter from Bro. Wm. Cross, also one from a Mr. Cook, chairman of a committee appointed by the engineers out at Rossland, asking information as to the starting of an association in that place. So you see if we have lost in the east we have gained in the far west, where everything grows in abundance, and to an enormous size. You will be asked to look over a bill drafted by a committee appointed by the Ontario Association, also to give your opinions and co-operations, that a greater effort may be put forth to have the bill become law, at the next meeting of the Local House. In this connection I should say that in this movement, not only are the members of the two associations a unit in favor of such a law, but I might add, almost all the qualified engineers of this country are with us, as well as most of the steam users. It may be necessary at the present convention to again take up the matter of bi-annual conventions, with a view to the curtailment of the expense necessary for an annual meeting. Steps should also be taken to arouse the engineers of the Dominion to the loss they sustain in not being of our membership. I regret very much the steps taken by our secretary, also by Montreal No. 1. I presume most of you have seen the item in The Canadian Engineer, that Montreal had moved to withdraw from the executive. For what reasons? Because they did not get from the executive the results desired in accordance to what they pay in, also that the cost of attending the convention was too great. Now, brethren, do you think that is the object? They have had for the past two years the executive secretary, a man possessed of good ability, and I consider it the most important office in the executive. So if they have not obtained what they want in the way of information it is their own fault. I think it would be wise to appoint some good past president to the secretaryship, and keep him for a term of years, and have him devise some scheme whereby the subordinate associations will be drawn in closer touch with the executive head. For instance, he might send out problems to the different lodges, for them to work out and return, and any errors they might make could be rectified by him, whereby keeping up a correspondence, and making the executive head a medium of instruction. These are a few points I have brought out for your consideration, and I feel satisfied that your best judgments will be used in dealing with them. The finances will be dealt with by the executive treasurer, therefore I will not touch on them. Brethren, in conclusion, I desire to express to you my deep sense of gratitude for the great honor you conferred on me a year ago, when you elected me to the high and honorable position of president of this association, and for the loyal manner you have stood by me. In closing I will only add it is my heartielt wish that your deliberations at this convention may be so conducted towards each other that everything we shall do will redound to the benefit and honor of our good association.

Moved by Bro. Wickens and seconded by Bro. Pettigrew, that the president's address be handed to the Committee on the Good of the Order for discussion.

The minutes of the last meeting were then read by Treasurer and Acting Secretary Bro. G. C. Mooring, who was handicapped badly, owing to the poor notes of last meeting, and press of business coming on him in his dual capacity; he regretted that they had not been put into proper shape. They were adopted on a motion by Bro. Dixon, seconded by Bro. Edkins. The president informed the married men accompanied by their wives that carriages would be ready for the ladies at 2.30, for the purpose of giving them a drive round the twin cities. On a motion by Bro. Marr, seconded by Bro. Ironsides, and carried unanimously, it was decided to adjourn until 3 p.m.

At the afternoon session Bro. Oelschlager introduced Mayor Eden, and several of the councillors, and the delegates and visiting engineers listened with great pleasure to the following speech, in which the mayor gave them welcome:

Address of Welcome by Mayor Eden, of Berlin.

It affords me very much pleasure to meet the delegates of the Canadian Association of Stationary Engineers, and especially is it a pleasure to greet you in our town of Berlin. I am glad to see that a number of the delegates have brought their wives with them, for I feel satisfied that they will retire much earlier in consequence. The stationary engineer fills a most important position in connection with the welfare of the country. In the first place, they virtually hold the key to our manufacturing industries, whereby the trade and commerce of the land is very much increased. They also control to a great extent the labor employed in cities and towns, and without this employment, the cities and towns of our country would be very much reduced in prosperity and population. This must show to the engineers the necessity of each of you being intelligent and ingenious. A man to-day to be of any use in any profession must be more than a machine. You are showing your wisdom in forming yourselves into an association and meeting regularly to discuss new requirements in your particular lines. No doubt many of you are clever individually, but all can learn from one another. It should be your object to try and benefit your employer by giving him as much power as possible with the least expense. Now as mayor of this town, I extend to you all a hearty welcome to our town of Berlin—a town which we boast of as being the best in this fair Dominion—a town which employs to-day more stationary engineers than any other town its size in Canada. I understand that only a few of our engineers have as yet joined the association, but I trust your meeting here will act as a stimulus and result in having all our engineers identify themselves with the organization. Our town is known as a most hospitable one, and I can assure you the freedom of the city wherever you go. No doubt you will be most interested in our manufacturing establishments, and I can assure you from what I know of our manufacturers, it will be a pleasure for them to show you through their factories. I trust you will enjoy your visit here in such a way that you will see fit to meet here again in the near future, at which time we will have all our streets fixed up in keeping with the rest of the town. I again extend to you, friends, the freedom of our town.

Reply to Address of Welcome from Mayor Eden, of Berlin, by President Chapman.

Mr. Mayor and Aldermen:—

On behalf of the delegates here present, attending our tenth annual convention, I thank you for the honor you have done us in welcoming us in such a handsome manner to your beautiful town, noted not only for the proverbial hospitality of its citizens, but also for their well known go-aheadativeness and public spirit. We join with you, Mr. Mayor, in pride of the beautiful cities, towns and waters of this Canada of ours, and not only those are we proud of, but we are proud of our fair Dominion at large, believing that it is bound to become one of the greatest and grandest countries on this earth. And, Sir, appreciating this truth, it becomes us as engineers, to sow the seed of theory and practice combined, which are the fundamental principles of our order. I am sure the delegates, one and all, appreciate as highly as I do your presence amongst us. We have come together to combine business with pleasure. The object of our association is to help one another, not only in a social and brotherly way, but chiefly to educate ourselves in our calling, thus benefiting our employers as well as ourselves; and I am sure we are more than pleased to hear from the eloquent welcome you have tendered us, that you thoroughly understand our aims and objects. I feel sure that our sojourn in your town will be most agreeable and pleasant for us all, and that we shall return home carrying with us happy recollections of our stay in the beautiful town of Berlin. Our branch here is composed of energetic citizens, as is evidenced by the programme of entertainment provided for the entertainment of their visitors. When we add to this the hearty co-operation with them of the Chief Magistrate, and citizens generally, we have indeed reasons to approve of the decision of last year's convention, in deciding to come to Berlin. I need hardly say, Mr. Mayor and Gentlemen that during the proceedings of this convention, we shall at all times be pleased to have you attend our sessions when you feel disposed to do so. We have met with cordial receptions wherever the conventions of the association have been held, but

nowhere has it been more generous and hearty than in Berlin. Again Mr. Mayor and Aldermen, on behalf of the delegates here assembled, I thank you for your welcoming us to your town.

Bro. G. C. Mooring, in his capacity as acting secretary, then read the annual report, and his report as read brought member after member to their feet. It was certainly incomplete in many details, and it looked at one time as if the executive were somewhat to blame. Secretary Robertson had, according to his letter of explanation, met with various and trying accidents, and other experiences, which had all tended to a complete abandonment of his official duties, and the report was finally referred, on a motion by Bros. Dixon and Moseley, to the Finance Committee for analysis. Bros. Wickens, Webb and Pettigrew demanded an investigation, and were answered by Bro. Edkins, who said it would not help matters any even if the executive were dragged into the matter; he was followed by acting secretary Mooring, who explained matters from his standpoint as acting secretary, and had done all he could to give them facts. For a few minutes the executive had a busy time answering questions, which came thick and fast, and the atmosphere cleared only when Bro. Mooring read a private letter to himself, and in which the secretary took all the blame. It was a revelation to the representative of The Canadian Engineer how such matters could be discussed in such a fair manner, and how straight questions such as were asked could be answered calmly and without any show of personal feeling. It speaks well for the manliness of the individuals composing the C.A.S.E., and many executive heads could get good pointers from our C.A.S.E. in convention. The matter, however, was finally referred to the following special committee, consisting of Bros. Webb, Wickens, Pettigrew, Edkins and Dixon.

Forwarded to the Committee on the Good of the Order for a report on same, and moved by Bro. Edkins, seconded by Bro. Pettigrew, that the committee be given until Thursday a.m. to prepare their report. The treasurer, Bro. G. C. Mooring, then read his report for the year.

The following notices of motion were then given:

That our conventions in future be held every alternate year or bi-annually, instead of annually as at present.—John M. Dixon

That the per capita tax be reduced from 70c. to 50c. per year. —Chas. Moseley.

That two days session in future be the limited time apportioned conventions.—John Marr.

The report of the Credential Committee was on motion by Bro. Dixon, seconded by Bro. Wickens, accepted and referred to the Mileage Committee. Bro. Dixon, who is an indefatigable worker, and one of long experience, then read the report of the Parliamentary Committee. A discussion followed the reading of this, led off by Bro. Ironsides, and participated in by Bros. Wickens and others, and after being fully discussed and ample explanation given it, was received by Bro. Edkins and seconded by Bro. Bain, and the committee was dismissed. In connection with this report it might be said that last year a committee was formed, and Bro. Dixon was the convener. The members of the committee were stationed far apart, and as a result no concerted action was possible, so they had failed in their object. It was brought out in the discussion, before referred to, that to be a success the new committee would be chosen differently.

A copy of the new bill, which is proposed to be submitted to Parliament, was distributed at this stage of the proceedings, and after a motion had been made by Bro. Mooring, a committee of one, Bro. Oelschlager, was appointed to have badges made for the delegates. Meeting adjourned.

The programme for the evening was varied, and it was thoroughly enjoyed by all. At 9 p.m. special trolley cars supplied by Manager McLelan of the Street Railway Company carried the executive, delegates and ladies to the Zimmerman House at Waterloo, where a reception was tendered them by Waterloo Association No. 17. A pleasant time was spent. Bros. John M. Dixon and J. W. Marr supplying the vocal music, and the variety of the contributions was very great; many of the choruses were taken up by the crowd, and Bro. Dixon gave a creditable exhibition of the duties of a chorus leader, his invariable good nature and sympathetic remarks lifting the chorus singers far above the plane on which they had started and the presence of a number of German friends did not deter him in achieving his object. The gentlemen friends of the party having received an invitation to a German supper from Mr. Wegener, the party left for Berlin about 10 p.m., and soon afterwards were enjoying this unique feast of pretzel, Limburger cheese, brown bread, weiners and other delicacies of the Fatherland. Past President E. J. Philip put in an appearance, having travelled from Toronto in his automobile, accompanied by his mother, an old lady of 74 years of age. Toronto was left at 11 a.m. and Berlin was reached at 8 p.m., having travelled 70 miles. This was the first auto-mobile to enter Berlin, and attracted great attention. Bro. Philip was the centre of attraction for the newspaper men, and the fact really was, he was the most talked of man in town. He introduced his brother, G. O., who is one of Berlin's successful merchants, the manager of the Opera House, and a liberal-minded citizen. Songs and stories helped pass the time, and the host sang several German songs, his rendering of the well-known "Der Wacht Am Rhine," being particularly enjoyed by the English members of the party. The inn, which is named the "Progress," is a fac-simile of the German style.

Handsome mural paintings adorn the walls, and scrolls containing mottoes similar to the following are entwined with the figures: "First weigh, then risk it;" "Love what is rare," "Drink what is clear," "Speak what is fair," "Eat what is pure." Needless to say this supper was a grand success and was one of the most pleasant experiences of the Berlin meetings.

The convention re-assembled at 10.30, Wednesday morning. The first business attempted was the reading of Finance Committee's report. It was adopted and the committee discharged on a motion of Bros. Moseley and Webb. Next came the report on the Good of the Order, and it was decided to take up the report clause by clause. Bro. Dixon read the report through and then submitted

Clause 1. Resolved that the president's address contains much that is essential to the vitality of the association. His references regarding our development has a slightly regretful tone, but the causes certainly cannot be laid to our charge; they rather lie at the doors of those associated with us at the time, whom it was impossible to control, much less coerce into activity. Adopted on a motion by Bros. Wickens and Moseley.

Clause 2. Resolved that the outlook for our extension in the near future has a hopeful aspect, inasmuch as enquiries have reached us from the Pacific Coast, requesting organization under the C.A.S.E. charter, wishing to enroll themselves as comrades in the march. We suggest that all such enquiries be closely attended to by our incoming executive. Adopted on a motion by Bros. Ironsides and Oelschlager.

Clause 3. Relative to Bill proposed at last session of 1898 convention. Your committee formed at last convention found it impossible to take action for the following reasons: The O.A.S.E. took up the matter enthusiastically, and obtained an interview with the Hon. John Dryden, M.L.A., and at his suggestion they amended the Bill, and intend presenting the new version at the next session. We, your committee, desire to impress upon the individual members the necessity of supporting this association in their efforts on your behalf. Amendment to Clause 3, proposed by Bro. Moseley and seconded by Bro. Pettigrew, That the committee should recommend that a special committee be appointed to act in conjunction with the O.A.S.E., as a further means of support, also that funds be placed at its disposal to help in the forwarding of their object, and that they be realized by a special appeal through the executive to the primary associations. The amendment was incorporated with the original and adopted.

Clause 4. Resolved that president's suggestion that a past president be elected to the office of secretary is a wise one. We wish to add the following, that said office of secretary be held for a term of not less than two years, and the official be eligible for re-election at the pleasure of the convention. Adopted on a motion by Bros. Pettigrew and Mooring.

Clause 5. This clause after a great difference of opinion was withdrawn. It provided for the holding of the C.A.S.E. convention bi-annually. Since the subject was first brought forward some years ago, no method of coming to an agreement had been proposed. The general opinion in former conventions was against it. Converts, however, have been made, and yet many of the delegates had come unmstructed as to how their

vote should be cast. Interesting discussion for and against resulted. Bros. Pettigrew, Dixon, Bain and others spoke against the change, and argued strenuously for an annual meeting. Some of the speakers demanded a live, working executive as a cure for the apparent waning of interest. Bro. Dixon, in a fair, impartial manner, took up both sides of the question, and left it in the hands of the individual members, by suggesting a plebiscite vote, and wished to move an amendment to that effect, which was done, and the amendment carried by a majority of three. In connection with above Bro. Pettigrew advanced an argument, which, perhaps, was not noticed much at the time, but was discussed freely outside the convention. It was argued by him that the Canadian Electrical Association was a competitor of the members individually of the C.A.S.E. Now the Canadian Electrical Association is composed altogether of electrical experts and employers of labor in plants operated primarily by steam power or water, and it does not appear reasonable to consider them in the light of competitors of an institution which exists chiefly for the education of steam producers.

Clause 6. Notice of motion by Bro. Moseley, that per capita tax be reduced from 70c. to 50c. Adopted on a motion by Bros. Pettigrew and Edkins.

Clause 7 was withdrawn. It dealt with the time limit of conventions, and it was found that the constitution had covered the ground fully.

Clause 8. Resolved that the executive be reminded that a motion stands on the books regarding the issuing of instruction papers. So far no course of instruction has been brought to our notice which would be so effective in retaining the interest of our members and to enable them to come in closer touch. Your committee begs leave to emphasize this present motion and suggests that strong pressure be brought to bear on your executive in regard to the preparation of these question and answer papers, of such paramount importance to our individual members. Adopted on a motion by Bros. Edkins and Ironsides. All of which is respectfully submitted. Bros. Dixon, Oelschlager, Moseley, Wickens, committee.

The president received a telegram from Goldie, McCulloch Co., inviting the delegates to visit their works in Galt, and it was decided unanimously to accept the invitation for the afternoon. The convention at 12.30 decided to adjourn until 9.30 a.m., Thursday.

After dinner the train was taken for Galt, and the trip down was very enjoyable. In fact beautiful weather during the whole convention was the order. Just a short distance from Berlin we ran quite close to the sewage farms, and so far the disposal of their sewage has been accomplished successfully by this system.

The C.P.R. bridge at Galt was also an object of interest, particularly because the bridge has been raised some few feet without in any way interfering with the traffic. At last Galt was reached, and as it was the first visit of many to this thriving and pretty city of factories, many were the exclamations of interest as delegates recognized the familiar names of machinery manufacturers whose products they had used. Easily the largest of them all was the immense stone block of their hosts, and as they filed into the office of the firm Mr. A. R. Goldie met them and personally conducted them through the different departments. Mr. Goldie has the faculty of conveying very much information in few words, and is perhaps the youngest man in Canada occupying such a responsible position, being general superintendent of the entire works.

It is needless to say that the visitors were very much interested, they having no idea that the Goldie & McCulloch establishment was so large. They were much interested in the engine department; the immense floor of the erecting room was completely filled with engines in different stages of construction. Some of these were as large as 400 and 500 h.p.; there were Wheelock slow speed engines, and Ideal high speed engines, the latter suitable for direct connected electric lighting. After visiting this shop they went into the machine shop where the very latest improved lathes, planers, etc., were all busily engaged turning out work for these engines and other machinery. System and good management were apparent on every hand. The very best facilities for handling heavy work are placed for the convenience of the workmen all through the shops. The writer noticed that the most modern of machinists' tools were used by the workmen, and it might be of interest to lathe and planer users to know that Goldie & McCulloch Co. was the first in Canada to install the patent tool holders and boring bars manufactured by the Armstrong Bros. Tool Co., of Chicago.

If these two shops were of interest, perhaps the moulding shop proved even more interesting. This immense department is 100 feet long by 90 feet wide, equipped with all the very latest appliances for handling ladles and heavy castings. There is one Whiting travelling crane, entirely operated with compressed air, the capacity of which is 40,000 lbs. In addition to this are six hydro-pneumatic swinging cranes, placed on each side of the floor, making it possible to pass ladles and castings from one end of the shop to the other. The cupolas, of which there are three very large ones, are placed at one end of the shop, as are also three great core ovens; at the other end is the cleaning room, which has cranes and compressed air appliances of all kinds for cleaning castings. The brass foundry is in this same building, but separated from the moulding shop proper. After visiting the shops mentioned above the visitors were taken through the other departments, the wood working machinery, the gas engine and the flour mill machinery department, the safe works and the boiler and other shops. While these different departments were of much interest to the engineers, of course it cannot be expected that they took the same interest here that they did in the engine construction department. President W. F. Chapman, in a few well chosen words before the delegates left, tendered a very hearty vote of thanks to Mr. Goldie for his kindness and courtesy in showing them through the works, and Mr. Goldie fittingly replied, after which three hearty cheers were given for the Goldie & McCulloch Co., Limited, of Galt, Ont.

The balance of the time in Galt was spent in sight-seeing and visiting the many friends of the delegates, and at 7.30 all arrived back in Berlin, the evening being spent in visiting Victoria Park and other points of interest.

The final session commenced at 9 a.m., Thursday. The Mileage Committee read their report and it was adopted on a motion by Bros. Edkins and Pettigrew. In consideration of his long services and ever ready assistance, Bro. A. M. Wickens' name was added to the list, on a motion by Bros. Dixon and Moseley.

Report of special committee was then read by Bro. Dixon. They had the difficult duty of analysing the reports and letter of the secretary. After deliberation they had drawn up a letter which was deemed satisfactory, and to show their good-will to the members of the Montreal branch, which had withdrawn, it was embodied in the letter that the C.A.S.E. ask them to accept as a gift the charter, by way of a practical illustration of the good will extended.

The new Bill occupied the attention of the meeting for a short time, and on a motion by Bros. Moseley and Pettigrew a new Parliamentary committee was formed, Bro. Dixon, convener, and Bros. Edkins, Webb, Moseley and Mooring members. The sum of $50 was put at their service for contingencies. A motion was also carried to the effect that the incoming secretary be requested to purchase a new supply of by-law and constitution books, and was adopted unanimously.

The election of officers was the next order of business. Two scrutineers were appointed, Bros. Walker and Bear. For president, Bro. Pettigrew, acclamation; vice-president, Bro. Mooring, acclamation. Bro. Dixon was also nominated but refused to stand. The secretary, under the new law, was to be selected from the past-presidents, and Bro. A. M. Wickens was elected on his past record, unanimously. The treasurer's position was the first to require a vote, and Bro. Moseley was the choice. The position of conductor also required a vote, and Bro. Oelschlager was declared elected. The position of doorkeeper was the most exciting and last official voted for. Three candidates offered were Bros. Bear, Turkington and Dixon, and Bro. Bear was the fortunate one. Past President Chapman then installed the new officers; Bro. Webb acting as conductor for the occasion. A vote of thanks was tendered the scrutineers. Toronto was selected as next place of meeting. The new president presented the retiring president with the handsome past president's jewel, and the few words spoken by Bro. Chapman were full of feeling, and expressed his deep gratitude for the honor done

him, marking the cessation of duties as the representative head of such an honorable body of men.

Votes of thanks were passed to the Berlin association and the chairman of the Reception Committee for his arduous and successful work, which had made their visit so pleasant, to which Bro. Oelschlager replied; the ladies of Berlin for their hospitality in entertaining the visiting ladies, and Bro. Steinmetz was appointed the bearer of this vote to them. The acting secretary, Bro. Mooring, was voted a sum of money as a slight acknowledgment of his services, and his reply was an expression of his desire to reach the highest office in the C.A.S.E., and he thanked them for placing him a step nearer his goal. Bros. Wickens and Moseley also expressed their thanks for the honors tendered them. A vote of thanks was tendered the local press, The Berlin News-Record being mentioned in particular. The Canadian Engineer was also tendered a hearty vote of thanks. President Pettigrew then delivered the closing address, and intimated his desire to build up the association. He was proud of the executive chosen, and the election of a past-president to the position of secretary would do much to strengthen his hands, and could only lead to the best of results. He prophesied a great future for the C.A.S.E. The present convention had done much to clear away the obstructions hindering their progress, and the next convention would prove what he said. The National Anthem was sung heartily, and the convention was over.

THE BANQUET.

The convention was brought to a close by a banquet in the dining hall of the Walper House. The attendance was good, and the Berlin association could be congratulated on the manner in which everything was arranged. Bro. Oelschlager acted as chairman, and was supported at the head of the table by the officials and prominent guests. The chairman read letters of regret from Mayor Eden; Goldie, McCulloch Co., Galt; J. J. York, Montreal, and others.

The toast of the Queen brought into evidence the patriotic spirit of the guests, and the National Anthem was sung heartily. "Canada Our Home," was responded to by L. J. Breithaupt, M.L.A., and in reviewing the history of Canada the speaker made the statement that the diamond jubilee was the means of making Canada better known than any other event in her history. As an employer of labor he dwelt on the dignity of labor, the great future in store for us, the increase of the exports from Berlin and her sister city. He said much had yet to be done in the making of Canada's great and unbounded possessions known. Great ignorance of the actual condition of affairs in Canada at times came to his notice, whether feigned or not he could not say, but he did not think our resources were realized by the nation to the south of us. He believed that there was no reason why in course of time Canada should not develop her resources so as to rival the progress of the United States. In the unavoidable absence of Mayor Eden, Dr. Bowlby, deputy reeve, spoke to the toast of "Mayor and Council. The trade and commerce of Berlin was his subject. The great manufacturing concerns were fully described, and the speaker informed them that they were there to stay. Messrs. Rumpel and Hagen also spoke a few words in their position as aldermen. Mayor Diebel, of Waterloo, although far from being a well man, made a pleasant speech, and his jocular references to the leading products of Waterloo were fully appreciated. The executive head and delegates came next. President R. C. Pettigrew lauded the C.A.S.E. for their efforts along educational lines and considered them the greatest educational body in Canada, outside the Public Schools. Education and progress were the corner stone and motto respectively of the society; although only in existence for a little more than twelve years, having had great difficulties in its path, and many prejudices to overcome, it kept steadily advancing, and now numbered over 20 branches, and if legislation such as they asked for was granted they would feel as if they had accomplished something. Vice President Mooring and Treasurer Moseley followed with remarks of gratification suggested by the good time they had enjoyed in Berlin. Manufacturing Interests was responded to by Samuel Rogers, president Queen City Oil Co. Mr. Rogers is a self-made man, and in his remarks connected with reminiscences of the winter of 1844 his experiences are typical of the hard road to success travelled by the farmer's son in the early days of a new country. At that time his sole ambition was to own a farm; however, when that object was gained, his ambition was still far from satisfied, and up through the years he kept advancing until his present position rewarded him. Canada's great wealth and the great future were subjects upon which the speaker spoke eloquently. His advice to the Canadians was to keep their resources and young men in Canada, particularly referring to the eagerness with which young men from our country were sought after by the business men of the neighboring Republic. Mr. Rogers concluded his speech with a detail of figures, and a very interesting account of the savings made in the oil factories from the utilization of the by-products. Mr. Anthes, a prominent manufacturer of Waterloo, also spoke. Educational interests were ably championed by Hugo Krantz, and his remarks were interesting in the extreme. With Germany as an example he related how she had taken steps when her trade was small, compared with other nations, to find out what she lacked. The establishment of technical schools and polytechnic institutions marked the beginning of a new era in her affairs of commerce, and to-day she stands in the front rank of the manufacturers. He made a strong plea for education of the practical man, and has worked for years on these lines, and the material in Canada, and the men were the equals of Germany, and Canada would prosper if that same idea that was embodied in the German manufacturing circles of training the working man first practical, then theoretical, was adopted. Sister associations were ably spoken for by E. J. Philip and A. M. Wickens, and their endorsation of the demand for legislation was strongly put, particularly by the last named. The Press were well represented, and as the hour was late their remarks were short. Messrs. Motz, Journal; Lutz, News-Record; Young, Electrical News, and Arch'd W. Smith of The Canadian Engineer, all replied to the toast. The Ladies were well cared for by D. B. Dover of the G.T.R. and G. O. Philip, both of whom spoke as if the subject was a pleasing one. Our Host and Hostess—in the absence of A. Walper, G. O. Philip spoke in his place, and the meeting dispersed with the familiar strains of "Auld Lang Syne," and "God Save the Queen."

Amongst the guests present were: H. D. McConochie, Galt; A. F. Masters, Detroit; Otto Werner, Sebastian Englert, R. Cossey, Aurcleas Moses, Alfred Vice, Albert Arndt, D. B. Doar, J. P. Wegener, Conrad Gildner, J. E. Belger, John Schneider, of Berlin; R. W. Turkington, Brockville; J. H. Clappison, Hamilton; G. Byers Towers, Jas. Bannan, Jas. Bain, A. E. Edkins, Toronto; H. A. Simpson, John L. Wendell, M. D. Caldwell, A. Stockfisch, Nath. Beam, John Nihell, Gideon Beam, F. A. Pflug, Jno. R. Uttley, of Waterloo; W. Mielke, New Hamburg.

W. OELSCHLAGER.

W. Oelschlager is of German descent, and was born in Waterloo county, Ont., in 1857. He learned the machinist's trade with J. Bricker & Sons, of Waterloo. Had two years' course in Worcester School of Technology, Mass., and graduated with honors. Was employed in the following shops: Chicago, West Michigan Railroad shops, Muskegon, E. P. Allis Co., Milwaukee, Chicago, Milwaukee and St. Paul railroad shops, Milwaukee, A. O. Pray & Co., Minneapolis, C.P.R., Winnipeg, and E. E. Gilbert & Sons, Montreal; was with this firm for three years and had charge of their machine shop for

two years, and left them in 1884 to start a shop himself in Port Elgin. Mr. Oelschlager carried on the shop for ten years, and five years ago removed his shop to Berlin. He has been a member of C.A.S.E. No. 9 for four years, and holds O.A.S.E. first-class certificate.

CHAS. MOSELEY.

Chas. Moseley, the newly elected treasurer of the Canadian Association of Stationary Engineers, was born at Chart, near Sutton, Eng. At the age of 11 he began his mechanical education by entering the machine shop of Steaven, Hooker & Co., and at 16 had charge of their steam plant. In 1884 he left England and sailed for Canada. Arriving in Toronto, he secured a position with John Fletcher, builder and contractor, as engineer. He remained with Mr. Fletcher for six years, leaving to accept a position with the Mail Publishing Co., Toronto, but after six months returned to his former employer, for whom he worked one year. Later Mr. Moseley secured the position of engineer of the North Toronto Electric Light and Waterworks, and in August, 1893, he accepted his present responsible position as chief engineer of the Incandescent Toronto Electric Light Co., on Terauley street, Toronto.

The portraits and biographical sketches of the other officers have already appeared in former issues of THE CANADIAN ENGINEER.

DRAFT OF BILL.

An Act for the protection of Life and Property in the use of Stationary Boilers and Engines, and the Examination and Licensing of persons in charge of them.

Whereas special provisions have been made by law for inspecting marine boilers and engines, and, as a result, the precautions made necessary by the owners in complying with the said law have had the effect of reducing accidents by boiler explosions to a minimum; and whereas the boiler explosions in the use of stationary engines and boilers have of late years increased alarmingly and been the means of destroying a large number of lives, and a great amount of property, through defective plant, the carelessness of owners, and the lack of knowledge of the men in charge; and whereas it is expedient in the interests of the public that the like means of prevention of such explosions and accidents should be applied to stationary boilers and engines, as to marine boilers and engines;

Her Majesty, by and with the advice and consent of the Legislative Assembly of the Province of Ontario, enacts as follows:

1. This Act may be cited as An Act for the Protection of Life and Property in the use of Stationary Boilers and Engines and the Licensing of Engineers in charge of them.

2. In this Act unless the contents otherwise requires.

(1) The expression "Boiler" does not include boilers used for heating water for domestic purposes or low pressure steam heating boilers, unless the pressure exceeds fifteen pounds per square inch, or railway locomotive or steamboat boilers, but means and includes all other steam boilers and every part thereof, or thing connected therewith, and all apparatus and things attached to or used in connection with any such boiler.

(2) The expression "Owner" means and includes any person, firm or corporation, the owner or lessee of the boiler, and the manager or other head officer in charge of the business of any such firm or corporation.

(3) The expression "Engineer" means any person having charge of or operating a steam boiler, under the provisions of this Act.

(4) The expression "Inspector" means any inspector of steam boilers appointed by the Lieutenant-Governor-in-Council under the provisions of this Act.

3. The Lieutenant-Governor-in-Council shall appoint an inspector or inspectors of steam boilers for the province, for the purpose of carrying out the provisions of this Act, and may fix the remuneration to be paid such inspector or inspectors, and may divide the province into districts, and appoint one or more inspectors in each district. Such inspectors shall constitute a board of boiler inspection, who shall meet from time to time as may be required, and who shall have power to formulate uniform rules and regulations for the inspection of boilers, and the examination of candidates for certificates of fitness as engineers under the provisions of this Act, and upon the approval of same by the Lieutenant-Governor-in-Council, such rules and regulations shall have the same force as the provisions of this Act.

4. No person holding the office of inspector under the provisions of this Act shall be either directly or indirectly interested in the sale of boilers or steam machinery, or any kind of supplies used in connection therewith.

5—(1) Every inspector appointed under the provisions of this Act shall, before entering upon the performance of his duties, take and subscribe an oath that he will faithfully and impartially perform the duties of his office, and also give security for the due performance of his duties in the sum of $2,000. He shall have had at least five years experience as a practical engineer in charge of a steam engine.

(2) Every inspector appointed under the provisions of this Act shall be practically conversant with the manufacturing and working of boilers, and shall also be a competent and practical engineer, especially conversant with the manufacturing and working of steam boilers, and shall hold the highest grade of certificate granted by the Ontario Association of Stationary Engineers, or a first-class engineer's certificate from the Minister of Marine and Fisheries, under R.S.C., chapter 78, section 41.

6. The inspectors appointed under this Act shall, under the direction of the Lieutenant-Governor-in-Council, make such rules for the uniform inspection of all steam boilers coming within the provisions of this Act, as will ensure the careful, thorough and systematic inspection of all boilers once, at least, in every year.

7. The provisions of this Act respecting the inspection of boilers shall not apply to any boiler insured and inspected by a duly incorporated or duly licensed boiler insurance company, legally doing business in Canada, if the owner or owners of such boiler shall, when required by an inspector appointed under the provisions of this Act, produce the certificate of inspection from such a company.

8. The inspectors shall examine all persons applying for certificates under this Act, and shall have power to issue certificates of competency according to the experience, knowledge and qualifications, subject to the rules and regulations made and approved of by the Lieutenant-Governor-in-Council, from time to time.

9. All certificates shall be exposed to view in a conspicuous place in the engine or boiler room.

10. Every engineer or fireman, or holder of a special certificate who undertakes to operate or take charge of any steam plant, requiring a higher grade of certificate than he possesses, shall be liable to a penalty not exceeding Fifty Dollars, and not less than Ten Dollars, upon the conviction of the same offence, and the inspector may revoke his certificate.

11. Every person who has charge of an engine or boiler to which this Act applies at the time of the passing thereof, shall upon the payment of a fee of two dollars to the inspector, be entitled to receive a permit to operate such steam plant for the term of one year, and every such engineer or fireman who applies for a renewal or higher grade of certificate, may procure the same by passing the necessary examination before the inspector, and shall pay for the certificate the sum of five dollars.

12.—(a) Every person to whom the provisions of the next preceding section does not apply, who presents himself for ex-

amination, shall pay the sum of five dollars for such examination. Each certificate shall have force and effect for the term of one year, unless sooner revoked for cause, and for each renewal the sum of one dollar shall be paid. The inspector shall not issue in any case a certificate to a person of intemperate habits, however skilful he may be.

(*b*) Every person who has had charge of an engine or boiler to which this Act applies at the time of the passing thereof, for the period of ten years prior to the time of the passing hereof, shall upon the payment of a fee of five dollars to the inspector, and upon furnishing proof of such service and of good character from his employers, be entitled to receive a second class certificate.

13. Every inspector appointed under this Act shall have power to revoke the certificate of any engineer in his district, if the person holding the same shall have committed any act or acts that shows him to be unworthy, incompetent or intemperate; but such person may appeal from the decision of the inspector to the Minister of Agriculture.

14. No person shall employ another as engineer, and no person shall serve as engineer unless the person serving or as employed as engineer is then licensed by an inspector as aforesaid, and any one who violates any of the provisions of this section shall be liable to a penalty not exceeding two hundred dollars, and not less than fifty dollars.

15. All moneys collected for certificates or renewals under this Act shall be paid to the inspector who issues the certificates, and who shall remit the same to the Provincial Secretary, together with a statement showing the names and addresses of the persons paying the same.

16. All prosecutions under this Act may be brought before any of Her Majesty's justices of the peace in and for the county in which the offence was committed, and in cities, towns and incorporated villages where there is a police magistrate, before such magistrate.

17. Every inspector shall keep a true record of all boilers inspected, and all repairs ordered by him, of all boilers condemned by him as unsafe, of all accidents to boilers in his district whether by explosion or otherwise, of all casualties in connection with boilers in his district.

18. Whenever any licensed engineer or inspector shall discover that the boiler he is operating has become weakened or unsafe, he shall at once notify the proprietor, owner or manager of the fact, and demand that they be repaired and made safe. If the owner, proprietor or manager shall refuse or neglect to have the needed repairs made, the engineer or inspector shall at once notify the board of inspectors of such refusal or neglect.

19. The board shall thereupon order a thorough inspection to be made, and, if said boiler proves on inspection to be unsafe, the proprietor or manager shall forthwith have the needed repairs made, and any owner, proprietor or manager who shall attempt to operate any boiler after such inspection, before having the needed repairs made, shall on conviction be fined not less than $ nor more than $

20. Any boiler operated at a pressure of fifteen pounds or less to the square inch, shall not come under the provisions of this Act, except those under sidewalks in cities or towns.

21. On the occurrence of an explosion from any boiler to which this Act applies, notice thereof shall be sent within twenty-four hours thereafter, to the inspector within whose jurisdiction the explosion took place, by the owner or by the user, or by the person acting on behalf of the owner or user.

22. The notice shall state the precise locality, as well as the day and the hour of the explosion, the number of persons injured or killed, in addition to the purposes for which the boiler is used, and generally the part of the boiler that failed, and the extent of the failure, and such other particulars, if any, as the Lieutenant Governor in Council may from time to time require.

23. If default is made in complying with the requirements of this section, the person in default shall on summary conviction be liable to a fine not exceeding one hundred dollars.

24. On the receipt of a notice of a boiler explosion the inspector shall fully investigate the causes and circumstances attending the explosion, and such investigation shall be held at or as near the place of such explosion by the said inspector, in such a manner and under such conditions, as the Lieutenant Governor-in-Council may from time to time deem most effectual, for ascertaining the causes and circumstances of the explosion, and for enabling the said inspector to make the report hereinafter mentioned.

25. The inspector making such investigation with respect to any boiler explosion shall present a full and clear report to the Minister of Agriculture, stating the cause of the explosion, and all the circumstances attending the same, as shown by the evidence, adding thereto any observation thereon, or on the evidence, or on any matters arising out of the investigation, which they may think right to make.

26. In the case of an explosion taking place on any stationary boiler for which the owner or user has not obtained a certificate of fitness, from an inspector under this Act, or from an inspector of a duly incorporated boiler insurance company, and any persons killed or injured thereby, or any property destroyed or injured, the owner or user of such boilers shall prima facie be deemed guilty of negligence, and liable for any injury occasioned by such explosion, and the onus shall be on the owners or users of the said boilers, to show that all reasonable and proper precautions had been taken to prevent such explosion or accident.

27. Provided that no part of this Act, except section 26, shall be deemed to apply or to affect the operations of steam engines or boilers, upon any farm for threshing, or other agricultural purposes.

28. For every inspection and certificate thereof under the provisions of this Act, the inspector shall be entitled to receive from the owner or user of a boiler a fee of five dollars. If two boilers are inspected at the same time a fee of eight dollars, and if three boilers are inspected at the same time a fee of ten dollars, and for each additional boiler inspected a fee of two dollars more.

MCLACHLAN ELECTRIC AND GASOLINE MOTOR CO., TORONTO.

Users of power do not need to be introduced to J. C. McLachlan, formerly of the Toronto Electric Motor Co., Ltd., and will be interested in the departure which he has made by adding the manufacture of gasoline engines, both marine and vehicle types, to the electric motors which he has successfully supplied for many years. The vehicle shown in the illustration is equipped with one of these motors and weighs complete less than 500 lbs. These engines can be applied to owners' traps. When equipped with base this motor is valuable for use as a small stationary engine. The marine type is very light, and weighs under 175 lbs. for 3 h.p. It has been installed in a launch 21 feet by 5 feet, for T. E. Caffe, of the Empire Cloak Co., Toronto, and is said to afford the most complete satisfaction in every way. All particulars may be had of the builders, The McLachlan Electric and Gasoline Motor Co., 94 Adelaide street west, Toronto.

C. F. McGill, mechanical superintendent of the Canadian General Electric Co., Peterborough, Ont., has moved his family from Schenectady, N.Y., to Peterborough.

REFERENCES.

In using the statistics in the foregoing tables, reference should also be made to the detailed tables under the respective captions further on in this volume, where many explanatory notes as to the statistics will be found. The following notes refer to the four preceding tables: *(a)* Except where otherwise specified. *(b)* Not enumerated. *(c)* Amount or value of crude mineral. *(d)* Partly estimated. *(e)* Estimated. *(f)* Amount recovered as a by-product. *(g)* Barrels of 300 lb. *(h)* Barrels of 400 lb. *(i)* Includes manganiferous iron ore; this is not duplicated in the report of iron ore. *(j)* Value per square, i.e., 100 sq. ft. lapped and laid; the weights are calculated on the basis 3 squares = 2,000 lb., but these figures are only approximately correct. *(k)* Kilograms or per kilogram. *(l)* Reduced to a basis of 66° B. *(m)* Average market price at New York. *(n)* Nominal. *(o)* Value before grinding. *(p)* Includes ocher, umber, sienna, and oxide of iron. *(q)* Includes salt used for the manufacture of alkali; the barrel of salt weighs 280 lbs. *(r)* Reduced to a basis of 58 per cent ash. *(s)* Includes a small amount made from spelter. *(t)* Average value of lake copper at New York, less 0.25c. per lb. *(u)* Includes spiegeleisen, though the total value is reckoned as if the whole product were ferromanganese. *(v)* Average market price at Pittsburg. *(w)* Troy oz. *(x)* Flasks of 76.5 lb. *(y)* Barrels of 42 gal. *(z)* Includes a comparatively small amount made directly from ores. *(aa)* Not included in the preceding tables.

Abbreviations: Sh. T., short tons (2,000 lb.), L. T., long tons (2,240 lb.); M. T., metric tons (2,204.6 lb.).

UNITED STATES MINERAL AND METAL PRODUCTION IN 1898.

The statistics of mineral production in the United States, as furnished by the producers and others for The Mineral Industry, Volume VII., compiled by Richard P. Rothwell, editor of the Engineering and Mining Journal, have now been completely collected and arranged, and are presented in the accompanying tables. These show a production which, in nearly all the more important substances, is the greatest ever recorded. The United States was, in 1898, by far the largest producer of iron and steel in the world; was second only to Great Britain—and then by a very small quantity—in the production of coal; and furnished more than half of the total copper supply of the world.

In accordance with the usual practice there is added to the columns containing the customary measures, others giving the weights, in metric tons, or other measures. Comparison with foreign reports is then easy, and the statements are recorded in a form which will be of still greater value hereafter. Mr. Rothwell hopes that, in a very few years, we may be able to dispense altogether with the column of "customary measures," and that the metric measures will then be the customary ones also. The figures in the table and the brief notes which follow will fully explain the course of the mineral production during the year 1898. The total value of the mineral production of the United States in 1898 was $700,816,750, against $648,804,899 in 1897. Of the production in 1898, $314,255,620 was the value of metals against $272,178,392 in the previous year, and $433,659,141 ores and minerals, against $407,913,912 in 1897. The values given for ores and minerals include $38,098,011 in 1898 and $31,287,405 in 1897 for bauxite, manganese and iron ores, which were used for making aluminum, ferromanganese and pig iron. These duplications were deducted in the aggregate values stated above. Eighteen secondary products for which statistics were collected, derived from some of the ores included in these totals, had an aggregate value of $49,432,829 in 1898, against $41,718,420 in 1897. There was also a production of copper, lead, silver and gold from foreign ores and bullion, valued at $58,948,125 in 1898, against $47,127,174 in 1897. In the preparation of the statistics for this volume the figures previously reported for 1897 have been revised in the light of later and more minute investigation.

THE LATE J. H. KILLEY.

The name of the late J. H. Killey, of Hamilton, Ont., was very familiar to the readers of The Canadian Engineer two or three years ago, when he was a frequent contributor to its columns. Mr. Killey died very suddenly from heart failure, August 10th. Just before retiring he complained of a slight cold, but about 2 a.m. he awoke Mrs. Killey, telling her that he had a choking sensation in his throat. Within a few moments he fell back on his pillow, expiring before medical aid could be procured. He leaves a widow and three sons, the latter being Wm. Killey, of Hamilton, Ont.; James, of British

Columbia, and Joseph, of Liverpool, Eng. The late Mr. Killey was born in Castletown, Isle of Man, on April 24th, 1824. He studied in the Grammar School in that town, and received a general commercial education. He had had from his earliest years a great love for machinery. His parents purchased for him "Lardner on the Steam Engine," and this he mastered before he was 12 years old. At 14 he constructed a crude model engine and boiler, and so excited was he when it was nearing completion that he could not sleep for thinking of it. His parents about this time determined on sending him to Liverpool, to one of the large foundries there, and prepared him for the foundry business by sending him for a couple of years to cabinet-making. There was great difficulty in getting the position of apprentice at Liverpool, as many parents at that time wished to have their sons learn engineering. He eventually entered the Brunswick foundry, and ended his apprenticeship in the Vulcan iron works, then owned by a cousin of the late W. F. Gladstone. Mr. Killey afterwards became foreman of a large foundry and later mechanical manager and partner in the Windsor machine works, near Liverpool. The American war, however, interfered with business to such an extent that he left England with his brother and came to Canada in 1864. He obtained employment with F. G. Beckett & Co., Hamilton, and later was foreman of the St. Lawrence Foundry in Toronto. He repaired, while in this firm's employ, the steamer "Rothsay Castle," a blockade runner, which had been brought up from Halifax by Captain Leach, after she had run one season. He was appointed engineer of this boat, which position he held for three years, until the Fenian raids were threatened. He was then appointed engineer of the gun boat "Prince Albert," which was engaged in guarding the river and lake coasts. She took troops and munitions of war from Collingwood to Sault Ste. Marie during the first Red River rebellion. Mr. Killey left the boat to build an oscillating marine engine and boiler which he had designed for the composite steamer "Adelaide Horton." The engine was built in Hamilton and the hull in Goderich. After this engine was completed, Mr. Killey began business in 1870 in a small way in Hamilton, but it soon increased to an important industry. In 1884 the business became the Osborne-Killey Manufacturing Company, and turned out steam road rollers, boilers, engines, and sewer pipe machinery. Since the winding up of this company, Mr. Killey was associated for some time with the late F. G. Beckett, and latterly has been employed as a consulting engineer.

ONTARIO VOLUNTEER FIREMEN'S ASSOCIATION.

At a convention of the Ontario volunteer firemen, held August 31st, in Toronto, a permanent organization was formed, and the following officers were elected: R. C. Clarke, chief of Merritton, president; F. F. Earl, Milton, first vice president; J. H. G. Horey, Merritton, financial secretary; Dr. Creegan, of Thorold, corresponding secretary, and William Miller, of Smith's Falls, treasurer. Executive Committee: George

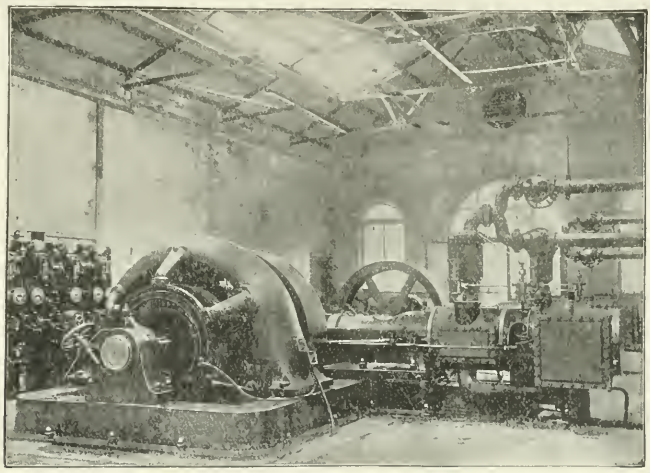
Johnston, Woodstock; Geo. Turner, Thorold; W. Smith, Trenton; A. Sargent, Toronto; and W. A. Thomas, Niagara Falls. Committee on By-laws: Riddell, St. Catharines; Skinner, Niagara Falls; J. H. Luscombe, Simcoe, and Tait, Alvinston. The next meeting will be held at Niagara Falls, Ont.

ISLE OF MAN TRAMWAYS.

The Isle of Man is the gem of the Irish Sea. It is only about 33 miles long and 12 miles wide, but every acre of its green, gorse-grown hills and rugged coast line is beautiful, and the quaint Manx language and customs which still survive make it doubly interesting to the visitor. It is situated almost in the centre between England, Ireland and Scotland, and being within easy reach, by swift steamers, of Manchester, Liverpool and Glasgow, has become a favored summer resort. Douglas, the principal town, situate on a beautiful bay, has a fixed population of about 30,000, which in summer rises to about 50,000. Every steamer from Liverpool, and other ports, of which there are several daily, bring hundreds who spend a few hours, days or weeks in this lovely spot. One of the chief attractions is the beautiful glens which indent the coast line, running up into the interior of the island between the hills. The Isle of Man Tramways Co., which operates an extensive system of cable and electric tramways in Douglas, has recently extended its electric line from Douglas to Ramsey, the next largest town in the island. The tramway runs around the precipitous cliffs overlooking the sea, skirting the beautiful Groudle, Laxey and Ballaglass glens. This drive, about 14 miles in length, winding in and out in full view of the sea, in an open electric car on a bright summer day, is very beautiful and most invigorating.

The recently completed extension of the I.O.M. tramways is a fine example of modern railway building and electrical construction. It is double tracked throughout, the roadbed is rock ballasted, and the bridges and culverts are of solid masonry. The over-head trolley is used, all the details of electric work being of the latest and best design and construction. Two large accumulator stations are used to equalize the load and assist the cars over the steep grades.

The motive power of the tramway is supplied from five power stations placed at various convenient points throughout the extensive system. The illustration represents the interior of the new power station at Ballaglass; it contains two 150 k.w. electric generators, manufactured by the Electric Construction Co., of Wolverhampton, England, directly connected to two 250 h.p. tandem compound condensing Robb-Armstrong engines, manufactured by the Robb Engineering Co., Amherst, N.S., Canada, for Dick, Kerr & Co., of London, who were contractors for the equipment. The station is also provided with two standard Galloway boilers and Ledwards electrically driven ejector condensers. Adjoining the power station is a large accumulator house, the whole making one of the most complete railway power houses in Great Britain. All the work of the Ramsey extension, including road-bed, electric lines and power stations, was done by the company's engineers.



Interior of Power Station, Ballaglass, I.O.M.

RAILWAY SUBSIDIES.

(Continued from last issue).

For a line of railway from Paspebiac, Quebec, to Gaspe, in the said province, not exceeding a distance of 82 miles.

Lake Erie and Detroit River Railway Company, for a line of railway from Ridgetown, Ont., to St. Thomas, a distance not exceeding 44 miles, this subsidy to be payable only in the event of adequate running rights over the Canada Southern Railway, between the two points above mentioned not being granted to the first-mentioned company on terms to be approved by the Railway Committee of the Privy Council.

Kingston and Pembroke Railway Company, for the construction of branches from the Company's main line to the iron mine at Bluff Point, and to the Martele mine, in the County of Renfrew, not exceeding five miles.

For a railway from Parry Sound extending northerly towards Sudbury, not exceeding a distance of 20 miles.

Resolved, That it is expedient to authorize the Governor-in-Council to grant the subsidies hereinafter mentioned toward the construction of the railways, also hereinafter mentioned, that is to say: The Ontario and Rainy River Railway Company, for a railway from Stanley station, on the Port Arthur, Duluth and Western Railway, to Fort Francis, for a distance of 140 miles, at $6,400 per mile, not exceeding in the whole $896,000.

To the Quebec Bridge Company, towards the construction of a railway bridge over the St. Lawrence river at Chaudiere Basin, near Quebec, one million dollars, payable 40 per cent., on monthly progress estimates approved by the Government engineers of materials delivered and work done.

To the South Shore Railway Company, towards the restoration and renewal of the railway bridge over the Yamaska river at Yamaska, Que., $50,000—Re-vote.

Towards the construction of a bridge over the Richelieu river at Sorel, 15 per cent., upon the amount expended thereon, not exceeding $35,000, re-vote, $35,000.

Towards the construction of a bridge across the St. Francis river, 15 per cent. of the amount expended thereon, not exceeding $50,000.

Towards the construction of a bridge across the Nicolet river, 15 per cent. upon the amount expended thereon, not exceeding $15,000.

To the Midland Railway Company, Limited, towards the construction of a bridge across the Shubenacadie river, 15

per cent. upon the amount expended thereon, not exceeding $33,750.

To the Great Northern Railway Company towards the construction of a bridge across the St. Maurice river, 15 per cent. upon the amount expended thereon, not exceeding $16,425.

Also towards the construction of a bridge across the Riviere du Loup, 15 per cent. upon the amount expended thereon, not exceeding $15,000.

Also towards the construction of a bridge across the Lac river, 15 per cent. upon the amount expended thereon, not exceeding $15,000.

Resolved, That the subsidies granted to the Ontario and Rainy River Railway Co., the Canadian Northern Railway Company and the Edmonton, Yukon and Pacific Railway Company, are granted upon the condition, and if received and paid under the authority of this Act, to the above-mentioned companies, respectively, shall be received upon the condition, that the said companies shall not, nor shall any of them, at any time amalgamate with any other railway company, or lease its line to any railway company; nor shall any of the said railways be leased to or operated by any other company; nor shall any of the said companies make an agreement for a common fund or for pooling its receipt with any other railway company, and any such lease, amalgamation or agreement shall be absolutely void, excepting in so far as such agreement may extend to traffic or running arrangements, which have been approved by the Governor-in-Council. Resolved, That the subsidies herein before mentioned, as to be granted to companies named for that purpose, shall, if granted to companies named for that purpose, shall, if granted by the Governor-in-Council, be granted to such companies respectively; the other subsidies may be granted to such companies as shall be approved by the Governor-in-Council, as having established to his satisfaction their ability to construct and complete the said railways respectively; all the lines for the construction of which subsidies are granted, unless they are already commenced, shall be commenced within two years from the first day of August next, and completed within a reasonable time, not to exceed four years from the said first day of August, to be fixed by order-in-council, and shall also be constructed according to description and specifications, and upon conditions to be approved by the Governor-in-Council, on the report of the Minister of Railways and Canals, and specified in an agreement to be made in each case by the company with the Government, which agreement the Government is hereby empowered to make; the location also of every such line of railways shall be subject to the approval of the Governor-in-Council. Resolved, That the granting of such subsidies, and the receipt thereof by the respective companies, shall be subject to condition that the Governor-in-Council may at all times provide and secure to other companies running powers, traffic arrangements and all other rights as will afford to all railways connecting with those subsidized, reasonable and proper facilities in exercising such running powers, fair and reasonable traffic arrangements with connecting companies, and equal mileage rates between all such connecting railways, and the Governor-in-Council shall have absolute control at all times over the rates and tolls to be levied and imposed by any of the companies, or upon any of the railways hereby subsidized. Resolved, That the said subsidies respectively shall be payable out of the consolidated revenue fund of Canada by instalments, on the completion of each section of the railway of not less than ten miles, proportionate to the value of the portion so completed in comparison with that of the whole work undertaken, to be established by the report of the said Minister, or upon the completion of the work subsidized, except as to subsidies with respect to which it is hereinbefore otherwise provided. Resolved, That every company receiving a subsidy under this Act shall each year furnish to the Government of Canada transportation for men, supplies, material and mails over the portion of its line in respect of which it may have received such subsidy, and whenever required shall furnish mail car properly equipped for such mail service, and such transportation and service shall be performed at such rates as may be agreed upon between the Minister of the department of the Government for which such service is being rendered, and the company performing the same, and in case of disagreement, then at such rates as may be approved by the Governor-in-Council, and in or towards payment for such charges the Government of Canada shall be credited by the company with a sum equal to three per centum per annum on the amount of subsidy received by the company under this Act.

THE INFLUENCE OF MECHANICAL DRAFT UPON THE ULTIMATE EFFICIENCY OF STEAM BOILERS.*

(Concluded from June issue).

RELATIVE COSTS.

2,800 NOMINAL H.P. PLANT, WITH CHIMNEY DRAFT.

2 additional boilers	$ 6,167
Settings, etc., for two boilers	1,250
Addition to building, etc	2,700
	$10,117

2,400 NOMINAL H.P. PLANT, WITH MECHANICAL DRAFT.

Fan, dampers and ducts	$ 1,500
Saving by using mechanical draft	8,617
	$10,117

Considering the matter of increased output solely in the light of comparative cost between the introduction of more boilers or the introduction of mechanical draft, and disregarding any possible cost of change in the chimney, we may again take for illustration the plant of 2,400 rated h.p. Suppose it is desired to increase its capacity to 2,800 h.p. or by 16 2-3 per cent. Then the relative costs under the two conditions will appear as here indicated.

We may now turn to that portion of our discussion which relates to the quantitative efficiency of a boiler plant. No greater waste occurs in modern steam boiler practice than that which is inherent in the employment of a chimney for the production of draft, namely, the loss of heat in the escaping gases. As the chimney depends for its action upon the maintenance of a temperature difference between the internal gases and the external air, it is manifest that with a chimney this waste can never be eliminated. It may be palliated, it is true, by the building of higher chimneys so that the same intensity of draft may be obtained with a lower stack temperature. But such means of providing for the utilization of the otherwise waste heat is expensive. In the case of a fan, however, the power expended as measured in heat units necessary to produce the same results, may, under ordinary conditions, be only abont one-seventy-fifth of that necessary with a chimney. In other words the fan renders available for utilization, practically all of the heat wasted by the chimney, while it possesses the further advantage of readily creating the additional draft required when heat abstracting devices are introduced. Donkin and Kennedy in seventeen independent boiler tests found the heat lost up the stack, when no economizer was used, to range between 9.4 per cent. and 31.8 per cent. of the total heat of combustion. As it is not practicable to cool the gases to atmospheric temperature it is evidently impossible to utilize all of the heat, but the ordinary economizer should, with mechanical draft, show a saving of between 10 and 20 per cent.

The importance of mechanical draft in the adoption of means for utilizing the waste heat, is well exemplified in the introduction of retarders and of ribbed tubes. Both of these increase the resistance and almost invariably require fan draft to enable them to create the saving of 5 to 10 per cent., which may be thus secured. The facility with which the intensity of the draft, and the volume of air supplied can be regulated when a fan is employed for draft production, has always been recognized as one of the most valuable characteristics of this method. Such regulations makes possible the most perfect distribution of the air, and its reduction to the minimum amount which will produce satisfactory combustion. For the mere chemical requirements of the combustion of one pound of ordinary coal, about 12 pounds or 150 cubic feet of air is required But under the conditions of chimney draft this amount is greatly exceeded. Donkin and Kennedy showed in the results of 16 tests that the air supply ranged from 16.1 pounds to 40.7 pounds.

*From a lecture by Walter B. Snow, before the Applied Science Graduate Society, McGill University.

As the gases pass onward through the tubes they become cooled, but those of higher temperature part most readily with their heat, and at the same time their volume and consequent velocity are reduced, still further facilitating heat transmission. On the other hand the gases of lower initial temperature transmit their heat less rapidly and the final result is that within practical limits the temperature of the escaping gases is least with the greatest excess of the air supply. The fact just presented points toward the economy to be secured by comparatively high rates of combustion, when the proper rate of heating surface to grate surface is provided. A high combustion rate manifestly requires a thicker fire, which in turn presents a better opportunity for contact between fuel and air with consequent economy in the supply of the latter. Less air results in a more intense fire, a higher furnace temperature, a greater transmission of heat to the water within the boiler, and a resultant higher evaporative efficiency. But a thicker fire requires a greater intensity of draft to overcome the increased resistance, while the relatively smaller area for passage of air necessitates a higher velocity of that air, and furthermore, the increased intensity to produce this velocity must be proportional to the square of the rate of flow. This condition is most readily met by the fan, which, under normal conditions, produces an intensity exceeding that of an ordinary chimney, and which can without trouble maintain the highest practicable rate of combustion.

The loss resulting from the formation of smoke is absolute, for it is equivalent to directly robbing the fire of a part of the fuel from which not only has no heating effect been secured, but upon which heat has actually been wasted in raising it to the temperature of the escaping flue gases. For the prevention of smoke, sharp, intense draft is necessary, properly regulated and capable of furnishing the required amount of air, both below and above the coal at the very moment when it is most needed. This result can be best secured by the introduction of mechanical draft which is ordinarily so regulated that the decrease in steam pressure resulting from the opening of the fire doors, the charging of the furnace, or the clearing of the fires, instantly causes an increase in the speed of the fan and in the intensity of the draft and the volume of air. A loss incidental to poor draft is that due to the formation of carbonic oxide. The formation of this gas instead of the complete product of combustion, carbonic acid, results from a lack of air. Sufficient air can best be secured by some means like the fan, which under automatic regulation increases both the intensity of the draft and the volume of the air when required. As a result, the pressure forces the air in sufficient quantity to all spaces between the fuel, and renders the combustion practically perfect.

By far the most important of the factors connected with the operating expense of a boiler plant is the cost of the fuel. When burned under suitable conditions, the decrease in its cost far outstrips its decrease in efficiency, so that the solution of the problem involves itself with the provision of the proper conditions. As a rule the cheap fuels, like the fine anthracites, require for their combustion an intensity of draft which the ordinary chimney is incapable of producing. The draft actually required under given conditions is clearly shown by these results of tests by Coxe:

RESULTS OF TESTS OF PEA AND BUCKWHEAT COAL.

Kind of Coal	Rate of combustion per square foot of grate per hour.	Pounds of water evaporated from and at 212° per pound of coal.	Air pressure in inches of water.	Maximum limit to size of coal in inches.
Oneida Pea Coal.	13.63	8.56	0.375	7-8
Oneida No. 1 Buckwheat	13.58	7.94	0.5	9-16
Oneida No. 2 Buckwheat	11.40	8.60	0.625	3-8
Oneida No. 3 Buckwheat	11.34	8.65	1.04	3-8
Eckley No. 3 Buckwheat	9.44	8.75	1.125	3-16

These coals, which are among the smallest in size, were burned on a special form of traveling grate, and the air pressure was maintained in the chamber beneath. It is noticeable that with practically constant combustion rate and evaporative efficiency, the draft increases very rapidly as the size of the coal decreases.

RELATIVE EFFICIENCIES OF VARIOUS COALS.

Kind of Coal	Water evaporated from and at 212° by one lb of Dry Coal.	Relative efficiency in p.c. Cumberland =100.	Cost of coal per ton	Fuel cost of evaporating 1,000 lbs. of water from and at 212°.	Relative efficiency in per cent measured by cost to evaporate 1,000 lbs. Cumberland = 100.
Cumberland	11.04	100	$3.75	$0.1698	100
Anthracite, broken...	9.79	89	4.50	0.2297	74
Anthracite, chestnut.	9.40	85	5.00	0.2660	64
Two parts Pea and Dust and one part Cumberland	9.38	85	2.58	0.1375	123
Two parts Pea and Dust and one part Culm	9.01	82	2.58	0.1432	119
Anthracite, Pea.....	8.86	80	4.00	0.2259	75
Nova Scotia Culm..	8.42	76	2.00	0.1187	156

The comparative efficiency of various coals as determined by Barrus is indicated in the accompanying table, which speaks for itself. The evidence in favor of burning low grade fuels is conclusive. Such results can, however, only be secured by positive and intense draft. It is true that as the quality of coal grows poorer and the size of the particles less, it becomes more necessary to provide some special form of grate or stoker for its proper burning. But even without an economizer to utilize the waste heat, the burning of cheap fuel by mechanical draft will, under perfect conditions, show a decided saving, after due allowance is made for fixed charges on the special furnace arrangements and for the cost of operating the fan:

Water evap. from and at 212° per lb. of coal.	ANNUAL SAVINGS RESULTING FROM BURNING CHEAP FUEL—COST PER TON.															
	$0.50	0.75	1.00	1.25	1.50	1.75	2.00	2.25	2.50	2.75	3.00	3.25	3.50	3.75	4.00
11.00											4,892	3,669	2,446	1,223	0,000
10.50										5,474	4,193	2,912	1,630	349	
10.00									6,115	4,770	3,424	2,079	734		
9.50							8,240	6,823	5,407	3,991	2,575	1,159			
9.00						9,105	7,610	6,115	4,621	3,126	1,631	136			
8.50					10,074	8,491	6,909	5,326	3,743	2,160	578				
8.00				11,180	9,478	7,797	6,115	4,433	2,752	1,070					
7.50			12,393	10,509	8,805	7,012	5,218	3,424	1,630						
7.00	15,724	13,803	11,881	9,959	8,037	6,115	4,193	2,272	350						

The possible savings with low grade fuels and mechanical draft are still further evidenced by the accompanying tables, which show for a 1,000 h.p. plant, the annual saving, based on 312 days of 10 hours each, which would result from the substitution of a cheaper fuel for say Cumberland coal, costing, in round figures, $4 per ton, and evaporating 11 pounds of water from and at 212° per pound of coal. Under these conditions the annual fuel expense would be $19,568. If the assumption be made that a coal costing $2.50, and evaporating only 9 pounds of water is substituted, the annual saving would be $4,621. The cost of operating the fan even if the exhaust steam was not utilized, and it required 1½ per cent. of the total coal burned, would be only $224, and if this were charged against the saving it would still amount to $4,397, a sum sufficient to show a most

creditable reduction in operating expenses, even if there was also charged against it any additional labor and the fixed charges on a complete equipment of the special appliances for burning the lower grade fuel. A reduction of over $125 per week, equivalent to $6,500 per year, has been made in actual practice in the case of a boiler plant of 1,000 h.p., by the introduction of mechanical draft and the burning of yard screenings with a slight mixture of Cumberland.

Of the advantages of mechanical draft which are purely qualitative in their character much might be said, but time will not permit. It must suffice to merely refer to the more prominent points of advantage. When the fan is employed for draft production, the steel plate construction, the comparative lightness, the portable character and the absence of heavy foundations, render extremely simple its adaptation to the exact requirements. Being portable it is also salable, and hence an asset of real value as compared with the chimney. It may be used either for forced or induced draft, and placed where it will occupy no valuable space. It may be operated by direct-connected or belted engine or motor, and so proportioned as to produce any desired draft pressure. In operation, the fan is both positive and flexible, independent of the weather but capable of regulation to the finest degree, and of adjustment to the necessities of the fire at any particular moment. A mere increase in the cut-off of the fan engine brings about a result only secured with a chimney at the expense of adding to its height, while a change in the fan speed alters both the volume handled and the intensity of the draft produced.

If this discussion of the influence of mechanical draft on boiler efficiency has rendered clear the factors concerned, it has with equal force shown that this influence is beneficial—in many ways markedly so. In the light of this fact the present active interest in the subject points to the future general substitution of the fan for the chimney.

THE CANADIAN BICYCLE COMBINATION.

A combination has been effected, which includes four of the leading bicycle makers in Canada, the Massey-Harris Bicycle Co., H. A. Lozier & Company, Toronto; the Goold Bicycle Company, Brantford, and the Welland Vale Bicycle Company, St. Catharines. The leading members of the new firm are: Geo. A. Cox, Toronto; Warren Y. Soper, Ottawa; W. E. H. Massey, Toronto; E. R. Thomas, Toronto, and Hon. Lyman M. Jones, Toronto. The probability is that W. E. H. Massey will be president of the company. There will be a general head office in Toronto, but the manufacturing will be done at the places where the present plants of the different firms of the company are located. The company will be a joint stock company, with a capital of six million dollars, so that the concern will have ample capital in its business; it has cost now several millions of dollars to buy these firms out. The name of the new company has not yet been chosen, but at once will make application for incorporation, either by obtaining a provincial charter, or by making special application to the Dominion Parliament for the charter. This year the output of these four firms has been more than 30,000 wheels, and with such excellent plants will not be compelled to have a new one for the manufacture of the automobiles. The firms mentioned are the only ones who were asked to deal in the matter, and it is the intention of the company to employ the same men on each staff as are now in the employ of the several companies. The new company will also build autocars.

LITERARY NOTES

Fox and Melben, of 40 Taylor street, Springfield, Mass., U.S.A., have put a new nipple holder on the market. Some of the reasons why this "Fox" nipple holder should be used are given on a neat blotter, the title of which is "Ten Reasons," and parties interested in the cutting of pipe nipples, either plain, brass or nickel plated, should investigate this matter.

The Toronto Brass Manufacturing Co. issue a handsome 20 page catalogue, beautifully printed and illustrated, showing display stands in great variety, paper mache figures, etc. One of their specialties is the manufacture of brass hand railings for engine rooms, stair rails; one of their latest contracts called for 600 feet of brass railing 2½ inch diameter, for new hall in exhibition grounds, Toronto.

Catalogue No. 3 of the Toronto Electrical Works Co., Ltd., manufacturers of electrical supplies, has reached us. It is unique in its construction; perforated ends in the place of binding allow the insertion of new sheets illustrating new goods added from time to time, and also allow of the dropping out of discarded lines. A glance through shows the different lines to which they give prominence. They manufacture the "American Watchman's Time Detector," which won the only medal for its class awarded at the Chicago World's Fair. The "Toronto Time Register" is a new time check, and is of unique construction, and they claim that it is the only time register which will not allow errors to creep in through mistakes made by the time clerk. A complete line of electrical supplies and tools, pole and line fittings, telegraph instruments, battery motors, lamps, cord tips, electro-magnets, lightning arresters, blow lamps, long and short line telephones, etc., all of which are profusely illustrated and described. Catalogue sent on receipt of enquiry.

The past decade has witnessed a great advance in the art of catalogue making, particularly in the machinery trades. The modern catalogue must not only be attractive, and this seems to have been the sole idea in some recent publications, but it must above all serve in the best manner possible its primary purpose of furnishing information. Illustrations must be clear, explanations explicit, and all information concisely given. The substantial character of most machinery demands similar character in the make-up of the catalogue describing it. Bold, clear type, black ink, good cuts, simplicity in composition, and first-class paper of good weight, all have a subtle influence in impressing the reader with the idea of the high quality of the article described. An excellent example of good catalogue making, in which this is the controlling idea, is presented by the B. F. Sturtevant Co. Their publications are of two classes. First, those which are purely educational in their character, comprising treatises on various special applications of fan blowers, reprints of lectures on similar subjects, leaflets regarding the attendant advantages, etc. Second, the regular trade catalogues of the standard dimensions, 6½ inches by 9 inches, each devoted to a specific line of manufactured goods. Separate catalogues in the same class bear the same cover design, but are printed and bound in different colors with proper titles, so that they may be readily distinguished. All catalogues are designated by individual numbers, the latest being No. 110. The most recent products are immediately presented by bulletins (designated by letters), preliminary to the issuance of complete catalogues regarding the given machines. Loss of time is thereby avoided, and the new designs can be sooner placed before the public.

The Journal of the Western Society of Engineers for June contains some specially interesting papers as "Experiments to Determine the Effects of Freezing on Concrete," by W. A. Rodgers, and the "Preservation of Timber," by S. M. Rowe.

We are in receipt of a copy of the fifth edition of the Slide Rule, a practical manual by Chas. N. Pickworth, Wh. Sc., which is a valuable aid to the use of this necessary instrument.

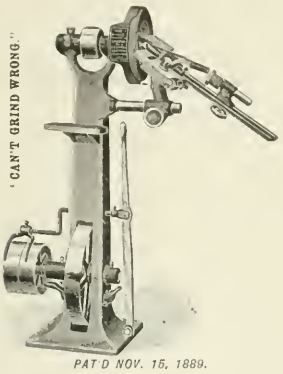
The Indicator Handbook is a practical manual for engineers, by Chas. N. Pickworth, editor of The Mechanical World. This book contains chapters devoted to the construction of the indicator, errors of the indicator, attachment of the indicator, indicator reducing gear, use and care of the indicator.

The new Canadian school songs have been composed for school celebrations by J. M. Harper, Ph.D., for many years rector of the Boys' High School, Quebec. They are "Hail to the Land," dedicated to Sir Wilfrid Laurier, and "Our Flag and Empire," dedicated to G. W. Ross, LL.D. The music is by F. C. Robinson and H. O'Connor Budden.

A feature of the National Export Exposition at Philadelphia will be an exhibit by the International Correspondence Schools, Scranton, Pa., illustrating their method of teaching by mail. The bound volumes of their instruction and question papers, as well as work done by students, including numerous drawing plates, will be shown.

THE YANKEE DRILL GRINDER.

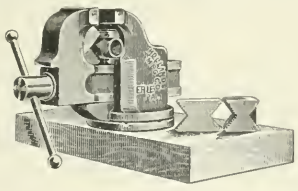
"Can't Grind Wrong." This suggestive heading has been used by the manufacturers of the Yankee Drill Grinder, with great success. As everyone knows that a twist drill badly ground will not bore true, nor will it bore a hole the exact size



of drill, it goes without saying that a grinder which does grind right is a great addition to any machine shop. The illustration printed herewith gives a good idea of the style of the machine. The Fairbanks Co. of Montreal is sales agent for Canada of this machine.

HOUGH'S EXTRA HEAVY COMBINATION PIPE VISE.

This combination vise is of inestimable value to engineers in mills, mining plants, steamboats, or to plumbers requiring a heavy vise. The makers claim that the castings used are of the highest grade, careful selection and the proper and intelligent mixing of the component materials, all tending to great strength. The workmanship is of the very best. The steel jaws firmly welded and finely tempered; the whole vise scientifically proportioned for strength and durability as well as convenience in use, and have no parts to get out of order. The particular vise illustrated is also fitted with reversible pipe jaws, giving prac-



tically two sets of jaws, as they can be turned end for end. Width of filing or plain jaws 4 inches; weight, 63 lbs. Swivel base, allowing the operator to work in any position, holds pipe from ⅛ to 2 inches, the larger vise holding ¼ to 3 inches. They also make a stationary base vise; capacity ½ to 4 inches.

The Hollands Manufacturing Co., of Erie, Pa., is not only vise manufacturer, but in their complete catalogue show planer chucks ranging from 6 inches to 30 inches capacity, "Acme" pipe tongs, Trimo & Stillson wrenches, roller and three-wheel pipe cutters, cutter wheels, pipe stocks and dies, also ratchet screw cutting stocks.

RAILWAY ENGINEERING.

Biggar, Samuel & Co.,

Gentlemen:—I received the copy of "Railway Engineering," by Prof. Smith, and while I was very pleased with the articles as they appeared in the "Canadian Engineer," I am more pleased with them in book form. I have read the book with interest, and often find it useful for reference, although I am not engaged in railroad work now. Wishing you success, I remain, yours truly,

F. W. Salmon.

Burlington, Iowa, August 6th.

Industrial Notes.

E. F. Munroe is building the new town hall in Windsor, N.S., at $8,286.

Macdonald Manufacturing Co., Stratford, Ont., is about to greatly enlarge its premises.

Jos. Orr, Stratford, Ont., furniture manufacturer, is installing a new Leonard engine.

J. S. Hogg is now manufacturing peat on the patented compression system near Galt, Ont.

Workman & Ward, London, Ont., iron founders and agricultural implement builders, are about to build new buildings.

Crescent Mill and Timber Co., London, Ont., is now completing its new factory, which is almost ready for the machinery.

W. W. Ogilvie will establish a 25,000 barrel mill and an elevator of 500,000 bushels capacity at Fort William, Ont., shortly.

R. S. Portuous, Stratford, Ont., is starting up a furniture factory for export trade in buildings formerly occupied by John Becker.

W. Partlo & Son are equipping the King mill at Ingersoll, Ont., as an oatmeal mill, and will put in new machinery, including steam plant.

The Toronto Cold Storage Co., Ltd., now has its plant in operation. The capacity is 80 tons per 24 hours, and is operated by a 150 h.p. engine.

J. W. and J. B. McManus, Memramcook, N.B., have a contract for Provincial Government on Tobique Narrows bridge substructure, and two highway roads.

Willis Chipman, who was the engineer for the Petrolia waterworks system, now has a similar position for the town of St. Mary's, where a $150,000 system is being put in.

J. W. Walters has started a machine and blacksmith shop in Dawson City, Yukon, and is going to turn out engines, boilers and mining machinery. During a recent visit to Montreal he bought supplies amounting to $30,000.

The shareholders of the Hamilton Steel & Iron Company have elected the following officers and directors: A. T. Wood, M.P., president; C. E. Doolittle, vice-president; A. E. Carpenter, C. S. Wilcox, John Milne, A. M. Wilcox and Wm. Southam. Robert Hobson is secretary.

The Massey-Harris Company is completing plans for the erection of a fine club house and library for the use of their employees on the north side of King street, opposite their premises in Toronto. The building, which will probably cost from $50,000 to $75,000, will include baths, reading room, library and social rooms, with a fine hall for public recitals.

Daniel and Ira Jacobs of Winona, Ont., narrowly escaped death, near Basingstoke, Ont., by the explosion of a traction boiler. The water tank became detached from the engine, and the Jacobs stepped down on the road to connect them. A few seconds later the boiler exploded, and scattered sections of the engine over the countryside; but, rather strangely, the Jacobs were not hurt in the slightest.

The Carter-Crume Company, check book manufacturers, Niagara Falls, N.Y., has been reorganized with a capital stock of $2,000,000. The new directors are: W. Caryl Ely of Buffalo, president of the International Traction Company; J. L. Morrison, S. J. Moore, W. E. H. Massey, president of the Massey-Harris Company of Toronto; J. W. Flavelle, president of the National Trust Company of Toronto, and Robert Kilgour, Toronto. S. J. Moore will be general manager.

The Fairbanks Company of Montreal has just furnished the Ontario Rolling Mills Co., of Hamilton, with an improved furnace charging scales of the suspension pattern. In this scale all the levers supporting the load are over head, thus leaving all the working parts free for inspection, and making them all the more durable. The scale has six beams to indicate the various required amounts of different material necessary for the proper composition of the product of the furnace. The scale is built of steel and iron throughout.

The income from Woodstock's waterworks this year amounts to $9,200.

A $35,000 waterworks by-law will be submitted to the ratepayers of Medicine Hat.

J. B. and J. W. McManus are to build the Burnt Church, N.B., wharf at $13,000.

The Hamilton, Ont., Bridge Co., is to build the Appleton, Ont., bridge; price, $2,500.

R. Grant, contractor, Toronto, is building the waterworks dam, London, Ont., at $40,000.

Hunter Bros., Kincardine, Ont., have finished the bridge over the Grand River at Elora, Ont.

Campbell Reeves, Montreal, has bought a controlling interest in the Canadian Locomotive works at Kingston, Ont.

The business of the Tingley & Stewart Manufacturing Co., Toronto, rubber stamps, dies, etc., has been bought by Bernard Cairns.

Willis Chipman, C.E., is superintending the construction of waterworks for St. Mary's, Ont., for which the council recently appropriated $25,000.

Leamington, Ont., has a tax rate this year of 15 mills. The town owns the water and gas plants, and the profits from these permit of this low rate.

C. W. Cadwell, of the Cadwell Silex Stone Co., has been appointed by the Amherstburg, Ont., Quarry Co. to take charge of the whole quarry output.

The Goldie-McCulloch Co. has recently been given an order for $4,000 worth of sugar making machinery by a company doing business in the city of Mexico.

The contract for supply of lumber and timber for the construction of the Dominion Iron and Steel Co.'s works at Sydney, C. B., has been awarded to A. F. Bury Austin, Montreal.

The Montreal Rolling Mills Co., has secured a site comprising about sixteen acres from the Dominion Iron and Steel Company, near the southern boundary of their works at Sydney, Cape Breton.

McManus and Lowe, contractors, of Halifax, N.S., have the contract for the foundations of the works of the Dominion Iron and Steel Co. at Sydney, C.B., the price being $150,000. Two years will be required to complete the plant.

The drilling of artesian wells for the Waterloo, Ont., waterworks by Leaper Bros., of Hawkesville, Ont., has been successful, as not only is the flow abundant, but the water is of excellent quality. The supply from the three wells sunk will be in the neighborhood of 750,000 gallons in 24 hours, at least five times the quantity consumed at the present time.

The Trent Valley Peat Fuel Co., Peterborough, Ont., has placed an order with the F. D. Cummer & Son Co., Cleveland, O., for a Cummer Dryer. The dryer will be used for drying peat preparatory for pressing into briquettes. The dryer will have capacity for evaporating 2½ tons of water hourly from the wet peat, which would give about 60 tons of dried peat per day of 24 hours.

A prophet is not without honor, etc. The aphorism would seem to apply to City Engineer Jones, who visited London, by invitation, a short time ago, to advise the aldermen how to stop damage from flood in West London, while Brantford city council consults a Hamilton engineer to devise means to prevent West Brantford from being flooded.—Brantford Expositor.

The Alberta Railway and Coal Co., Lethbridge, N.W.T., has ordered two 150 h.p. Mumford improved boilers from the Robb Engineering Co. It has had three of them in use for about a year, and this order speaks well for the satisfaction they have given. The makers of these boilers claim they are more efficient than any other type in use, while they cost less than a water tube boiler.

The Hamilton Bridge Works Company is rushed with orders, and is said to have work enough ahead for eighteen months to come. Its premises are too limited to permit of increasing its facilities on the site now occupied, but negotiations are proceeding through R. Maclay, for a five acre site in the northeastern part of Hamilton, Ont., where a considerable extension of the works would be made.

The Revelstoke, B.C., council has appointed S. L. Saunders chief of the fire brigade at a salary of $80 per month for the balance of 1899. The council will establish an electric fire alarm system at an estimated cost of $600.

Frederic Duclos, plumber, 78a Inspector street, Montreal, has assigned at the instance of the Star Iron Company, with liabilities of about $25,000. The chief creditors are: Dame F. Duclos, $9,000; Royal Institution for the Advancement of Learning, mortgage, $8,700; Walter Andrews, mortgage, $3,500; D. Nicholson & Co., $1,333; Star Iron Co., $859; A. Prudhomme et Frere, $614; T. H. Goulet, $520; Chas. Depocas, $600; J. Douglas, $500; S. A. Phillips, mortgage, $1,250.

The Maritime Stove Foundry Association was in session early in August in St. John, N.B. Halifax, Yarmouth, Moncton, Sackville, Amherst and St. John makers were present. A satisfactory agreement as to prices of hollow ware was reached. It was determined to increase the price of repair castings to six cents per pound and to increase the price of stoves and other foundry products five per cent., the change to take effect at once. A resolution was adopted urging retailers to form local associations to overcome the evil of price cutting.

The Hoepfner Refining Company, Ltd., Hamilton, Ont., has been granted letters of incorporation. Carl Hoepfner, of Frankfort-on-the-Main, Germany, doctor of philosophy, is at the head of the undertaking. The company purpose "to mine smelt, refine, manufacture and sell zinc, lead, copper, nickel and other metals." The share capital of the company is placed at $600,000. The provisional directors are Messrs. Carl Hoepfner, David Maclaren, Ottawa; Andrew T. Wood, John M. Gibson, John Moodie and John Patterson, Hamilton, and Nathaniel Dyment, of Barrie.

The McEachren Heating and Ventilating Co. had a very prominent exhibit of their fans, blowers and valves at the Toronto Exhibition. One feature was a handsomely decorated 24-inch fan in operation. There was a stock of blowers ranging from 30 inches to 90 inches in diameter; a boiler feed pump, and samples of the firm's new back pressure valve, ranging from 2 inches to 6 inches, and which can be used on either horizontal or vertical pipe. The firm's hot water heater "Little Wonder," was also shown in the stove building. This firm has the contract for the heating and ventilating plant of Prince of Wales College at Charlottetown, and the P.E.I. hospital of the same city. The 90-inch steel-plated fan shown at the Exhibition has been sold to the Granby Rubber Co., to be used for drying rubber.

Electric Flashes.

D. F. Whidden has bought out the Antigonish, N.S., electric light works.

The Kay Electric Motor Company has assigned to Sheriff Middleton, Hamilton.

At a recent directors' meeting the Royal Electric Co. declared a quarterly dividend of 2 per cent.

The electric light building at Wolfville, N.S., which was destroyed by fire a short time ago, will be rebuilt at once.

A project to put in an electric street railway will probably come before the Chatham, Ont., council in the near future.

The electric plant at Petty Harbor, Nfld., is now under construction. A head of 200 feet is being made available.

The Rossland Sentinel has installed in its printing establishment one of the Royal Electric Co.'s S.K.C. two-phase motors to drive the presses.

A project is mooted to connect the various small towns along the Rideau canal and lakes by means of a trolley line. A very large water power is available at Jones' Falls, Ont.

Frenyear and Batmeyer of the Westinghouse Electric Co., Buffalo, and E. Baxter, Fort Erie, Ont., propose to build an electric line from Fort Erie to Chippewa, Ont.

It is said that the Royal Electric Co., of Toronto, has made application for a franchise for an electric railway between Barrie and Allandale, a distance of about a mile.

T. W. Clark, Bridgewater, N.S., has the contract for constructing a power house, wheel pit, conduit and tail race at Milton, N.S., for Liverpool's electric light system, at $2,750.

The several companies that control the pulp mills, the electric plant and water mains, the carbide and iron works at Sault Ste. Marie, Ont., have been consolidated and capitalized at $6 000.000.

It is stated that the two electric companies of St. Hyacinthe, Que., may soon pass into the hands of M. Dubrocard, Lyons, France. It is said that the price to be paid is in the vicinity of $175.000.

The name of the Cataract Power Company of Hamilton has been changed to the Hamilton Electric Light & Cataract Power Company, and the capital is permitted to be increased from $250,000 to $3,750,000.

An action for $10,000 damages has been entered against the Royal Electric Company by J. Cyr, father of the boy who was killed on St. Louis street, Montreal, a few weeks ago while trying to catch a bird on the branch of a tree.

We understand that the Cleveland Seed Co., Picton, Ont., has placed an order with the Royal Electric Co. for a complete electric lighting plant for its warehouse. The dynamo is of 200 light capacity, and about 100 lights wired up.

The city of Hamilton has received $3,789.55 in street railway percentage for the last three months. The city of Toronto has received $12,721.03 from the same source for the month of July alone. The city of London has just paid out $3,400 for militia expenses on street railway account.—London Advertiser.

J. C. Clark, Ayr, Ont., is promoting an electric railway from Berlin to Port Dover, Ont. No bonus is asked, only the right of way through the towns. The road starting from Berlin is to pass through Waterloo, Ayr, Paris, Brantford, Boston, Waterford and Simcoe, to its terminus at Port Dover.

A number of the electrical men employed by the Electric Light & Power Company and Bell Telephone Company met at the Victoria Hotel, Hamilton, Ont., and discussed the advisability of forming a local branch of the International Electrical Association. Another meeting will be held shortly, when the electrical workers, including linemen, etc., may organize.

The Central Manufacturing Co., Chattanooga, Tenn., has furnished materials for the power plant at Ogden, Utah, U.S., and the plant of the Telluride Power Co., Salt Lake City, U.S. The Central Manufacturing Co. makes a specialty of yellow pine cross-arms, oak and locust insulators, pins and brackets.

The Renfrew Electric Light Company is being organized with a proposed capital of $50,000, of which about one-half has been already subscribed. The new company will embrace at least one of the existing electric lighting companies, and will undertake to supply power as well as light. It is an outcome of the development of the water power of the Bonnechere river, at Renfrew.

Thos. Vaughan, a young man employed in the Royal Electric Co.'s works, Montreal, was seriously injured, August 30th. He was working at one of the dynamos, and turned the wrong switch, with the result that he received a current of 10,000 volts. He fell unconscious, but when taken to the hospital revived, and is recovering.

Users of electric lights in Parrsboro, N.S., pay 19 cents for 10, and 30 cents for 16 candle power, with an all night service. Until lately, although the streets are well lighted with 28 arc lights, enough profit was made out of the incandescent services at the prices charged to pay for the street lighting, which in many towns would cost between two and three thousand dollars.

At a recent meeting of the directors of the Lachine Rapids Hydraulic and Land Company the statement of the company's business for the half year ending June 30 was very satisfactory, showing a gain of a hundred per cent. over the corresponding period last year. The directors declared a half-yearly dividend of 2 per cent. on the paid-up stock of $1,250,000. This dividend was earned after paying 6 per cent. interest on $600,000 worth of bonds. It was also stated that W. Davis & Son, contractors, had been paid in full; and that satisfactory progress was being made at the new works.

The Hamilton street railway has been taken over by a syndicate representing the Cataract Power Co., composed of Hon. J. M. Gibson, J. Dickenson, J. Moodie, Hamilton, and J. A. Kammerer, Toronto.

The Aptus Veneer Company, Albert, N.B., has placed an order with the Royal Electric Co. for a complete electric lighting plant for its works, the plant to be in operation within four weeks of date of order.

Bennett Bros., who own and operate a flour mill at the corner of Parke and Market streets, Hamilton, Ont., are installing in their premises a 40 h.p. S.N.C. motor to drive their mill, power being supplied by the Cataract Power Co.

The Willson Carbide Works Co. has orders much in excess of its capacity. When the new works at Ottawa are completed the company expects to be better able to keep up with this enormous and growing demand for calcium carbide.

Work has been begun on the development of the Shawenegan Water and Power Co.'s plant at Shawenegan Falls, Quebec, and is being pushed night and day. The Royal Electric Co. has installed for the contractors one of their 15-light T.H. arc machines and lamps, lighting the entire work.

The Hamilton screw works of the city of Hamilton are another of the converts to electric power, having shut down their steam plant, and are now being supplied with power from the wires of the Cataract Power Co. The Royal Electric Co., of Montreal, is installing a 40 h.p. S.K.C. two-phase motor. This adds another smokeless chimney to the many now in Hamilton.

Henry T. Duck, Toronto, of the Engineering Contract Company of New York, has just been awarded a contract by the Canadian Electric Light Company of Quebec for a large concrete dam, with sluiceway and bulkheads, the foundations of power house, supports for flume pipes, tail race, etc., at the Chandiere Falls. The contracts for the power house, the hydraulic and electric machinery and the transmission line will be awarded in a short time, and it is expected that the company will have power to dispose of in this city within some nine months. T. Pringle & Son, of Montreal, are the engineers in charge.

Liverpool, N.S., is installing a complete electric plant to furnish arc and incandescent lights for the streets, and incandescent lights for indoor use. The by-law was voted on some time ago, and an order has been given to the Royal Electric Co. for a complete electrical equipment, consisting of one 75 k.w. S.N.C. two-phase alternating current generator, with exciter and switchboard complete, also a complete switchboard and regulating apparatus for twenty-five 2,000 C.P. enclosed alternating arc lamps for the streets, as well as the necessary transformers and materials for installing 2,000 incandescent lamps, the whole plant to be in operation within six weeks.

Contracts have been let for the construction of a building to be temporarily occupied by the Edgerton Storage Battery Company, Hamilton, Ont. The building will be 75 by 125 feet, one story high. As soon as the building is in running shape another building will be erected for a main factory, and this one will be used as a storehouse. It is said the company will shortly be capitalized at about half a million dollars, and has work now ahead sufficient to guarantee its success. It is the intention of the company to use the Hamilton works for its export business. The zinc that will be used in the construction of the batteries will be supplied by the Hoepfner Refining Company.

The new steam plant power house of the Metropolitan Street Railway Co. at Bond Lake, has been equipped by the Goldie & McCulloch Co., of Galt. There are two cross compound condensing Wheelock engines, 17½ inches and 32 inches by 42 inches, and supplying 1,000 h.p. The fly-wheels are 18 feet diameter and 44 inches face. There is a battery of four boilers, each 73 inches diameter and 16 feet long. The electrical equipment is of the Westinghouse type, the order having been placed with W. A. Johnson, under whose superintendence the plant was installed. There are two 275 k.w. generators at Bond Lake, and two 250 k.w. generators at the sub-station at York Mills. The plant is arranged so that alternating and direct current can be used interchangeably.

One man was instantly killed and another seriously injured by coming in contact with a live electric wire at Sherbrooke, Que., August 26th. Louis Benoit, whose home is near Waterloo, Que., was killed, and Simeon Roy, of Sherbrooke, seriously injured. They were in the employ of the Gas and Water Company, and had been instructed to remove a certain arc lamp. Not having a crank to the windlass by which the lamps are lowered, Roy took hold of the cable which runs up the pole, and to which the lamp is suspended. In lowering the lamp in this way he pulled this wire to one side, and it came in contact with the electric light wire above. When he felt the shock he shouted to Benoit to cut the wire. The latter seized his pliers in one hand and with the other grasped the deadly wire above the place where Roy held it. The result was that the full current of 2,000 volts passed through Benoit, and Roy, who held the wire lower down, was relieved and fell to the ground unconscious, but alive. Benoit was dead before help reached him. Roy will recover.

Railway Matters.

The C.A.R. train between Montreal and Ottawa, Ont., jumped the track August 9th and seven persons, including the engineer, were killed.

Two locomotives for the Quebec & Central Railway are being built at the Kingston Locomotive Works. The boilers for these two were tested recently.

The Hull City Council has decided to give H. J. Beemer a $30,000 bonus towards the erection of railway shops, etc., in Hull. A by-law will be submitted to the people.

C. R. Reid is building the stations on the Coast Railway, N.S., at Lower East Pubnico, Wood's Harbor, Upper Wood's Harbor, Shag Harbor, and Barrington Passage.

In anticipation of an extraordinarily large grain crop in the North-West and Manitoba, the C.P.R. has this season added 2,000 box cars, making 6,500 available for handling the present crop.

E. Berryman, C.E., has completed the exploration survey of the Atlantic & Lake Superior Railway Company, between Port Daniel and Gaspe Basin. The railway will reach Gaspe Basin by the valley of the York river.

A new station building at Rat Portage, and a twenty-stall roundhouse with turntable, for the Canadian Pacific Railway, together with rock excavation for extension of tracks to company's yards at Rat Portage, is now going on.

It is said that after many months of surveying and the expenditure of much money, the C.P.R. engineers have at last discovered a feasible route for a railway over the divide between the Kettle and Okanagan River valleys, and to the south of Camp McKinney.

Wm. Mackenzie has closed contracts in five-mile sections of the Rainy River railway with John C. O'Neill, of Kemptville; John R. Turnbull, Winnipeg; McGillivray and Gleeson, Hugh Mann, and Luke Madigan, aggregating fifty-five miles to be finished before winter sets in. John R. Turnbull also received a contract for building all bridges and trestles between Stanley and Fort William.

Notice is hereby given that an application will be made to the Parliament of Canada, at the next session, for an act to incorporate a company under the name of the Deutsche Klondeik Gesellschaft to construct a railway from Dawson City in the Yukon Territory, along Bonanza Creek and across the Dome to Dominion Creek, covering a distance of about fifty five miles, with power to build branch lines, etc.

A horse and carriage containing five passengers made a trial trip across the new Victoria Jubilee bridge last month from the Montreal side, and returned. The occupants of the carriage were G. B. Reeve, general traffic manager; F. H. McGuigan, general superintendent; J. M. Herbert, superintendent of the eastern division, R. P. Dalton, superintendent of Montreal terminal, and F. H. McGuigan, son of the general superintendent.

The mammoth new round house of the Grand Trunk Railroad at Sarnia has been turned over to the company. It is one of the finest of the kind on the Grand Trunk System. The round-house, which is situated about a half mile west of the depot, is built of white brick, with stone foundation and gravel roof. The total length is about 760 feet, the depth 76 feet, and the height 20 feet. There are 30 engine stalls, each accommodating one locomotive. The foundation of these stalls is composed of four feet of brick, and two feet of cement. They have been thoroughly tested and have proved entirely satisfactory to the company's inspector. In addition to the round-house proper, there has been constructed an office and machine shop building, 56 feet by 32 feet, and a 70-foot turntable.

Mining Matters.

A single crystal, weighing over half a ton, was taken from the Tett Bros'. mica mine, near Westport, Ont., recently.

T. B. Caldwell has sold his iron mine at Calabogie, on the K. & P. railway, to the Hamilton Steel & Iron Co., Limited, Hamilton.

George E. Vickers, vice-president and manager of the Canadian-American Oil and Natural Gas Co., is boring for oil near Belleville, Ont.

Natural gas has been discovered at Clarkson, between Toronto and Oakville, Ont. But as yet the quantity available has not been determined.

The British Columbia Southern Mine, Ltd., operating the Gertrude mine in Rossland, B.C., has ordered a complete lighting plant from the Royal Electric Co.

A rich find of free gold is reported as having been made near Wabigoon, Ont., north of Dinoric, in the neighborhood of Lake Minnistuttle, by Jos. Bouston, a prospector.

Nichols & Son, of New York, have secured an option on the George McIlraith iron mining property on the fourth concession of Darling, Lanark County, Ont., and will develop it in the next few months.

It is reported that a large vein of copper has been discovered, extending from White Horse Rapids, on the Yukon, to a point on the Dalton trail forty miles from the Lynn canal. It is said to be exceedingly rich.

Near Cascade, on the Columbia and Western railroad, which the Canadian Pacific is building from Rossland into the Boundary Creek district, McKenzie & Mann, contractors, have discovered ore, running high in copper, gold and silver. Assays have shown as high as $50 to the ton.

The Coleraine Chrome Mining Company has been incorporated with an authorized capital of $300,000, and headquarters at Montreal. The incorporators are: Hanson and Ferguson, brokers; R. Wilson Smith, Hon. A. A. Thibaudeau, W. E. Blumhart and Honore Favreau, Montreal, and Hon. A. Desiardins, Maisonneuve.

Paul Johnson, M.E., a graduate of the Royal Technical High School and Mining Academy, of Stockholm, Sweden, is to superintend the building of the smelter of the British Columbia Copper Smelting Co., at Greenwood, B.C., together with John Norborn, of the Union Iron Works, San Francisco, which company has the contract for the iron work.

The Sultana mine, Lake of the Woods, has been sold by J. F. Caldwell, the sole owner, to an English company for $750,000. The mine comprises about 70 acres, with a vein about 30 feet wide on the surface, and running about $7 to the ton in gold. Its gross output for three years, with a ten stamp mill, averaging $3,000 per week, and with the thirty stamp mill put in last fall the earnings have been at the rate of $151,000 per year.

James P. Howley, F.G.S., geologist to the Government of Newfoundland, has recently presented an official report on the mineral exports of the colony from 1888 to 1898, inclusive which will shortly be published. In regard to the copper ore Mr. Howley gives a list of figures showing the export of

copper each year from 1888 to 1898; the value of which he finds to be $5,907,638. The value of iron pyrites, mainly shipped from Pilley's Island, during the same period, was $1,522,250. Chrome iron was shipped to the value of $70,890, mainly from Port-au-Port. The value of iron ore shipped from 1895 to 1898 was $200,140. The total value of all minerals exported, 1888—98, was $7,829,158. Of slate, $1,350 worth was shipped in 1898, and of the last-named article Mr. Howley states that some of our deposits are equal in quality to the best Carnarvon slate in England, and better than any used in the United States. Of the petroleum wells at Port-au-Port, Parsons' Pond and other places, Mr. Howley speaks in favorable terms. Indications of petroleum have been found over large areas on the west coast.

Personal.

S. S. Glass has been appointed to the charge of the electrical and steam plant in the Victoria Hospital, London, Ont.

E. I. Sifton, manager of the Electrical Construction Company, London, Ont., was married a short time ago in that city to Miss Kate Kelley.

J. J. York, engineer, in charge of the plant in the Board of Trade Building, Montreal, has resigned, and accepted a similar position in the St. Lawrence Sugar Refinery.

Arch. Rankin, marine architect, who formerly practised in Toronto, and is now chief architect to the American Shipbuilding Co., a combination of shipping interests recently effected at Cleveland, was recently in Toronto on a visit.

J. A. Calder, of Halifax, N.S., and member of the well-known firm of Wm. Muir & Sons, spent a day in Toronto on his way west. Mr. Calder was taking estimates for a cornmeal plant he proposes to install at Dartmouth, N.S.

H. P. Archibald, engineer, formerly of Antigonish, N.S., has been appointed superintendent of the Lethbridge, N.W.T., Waterworks & Electric Light Co., Ltd., and has now taken over the charge of these works.

W. A. Peck, representing the O. W. Bullock Co., of Springfield, Mass., was in Toronto for a few days last month. Mr. Peck is a well posted traveller, and has been engaged in the tool supply trade for some years past.

W. B. McLean, a graduate of McGill College, Montreal, for the last three months employed in the drafting room of the Robb Engineering Co., Amherst, N.S., will continue his technical studies in Manchester, England.

John Bosence, locomotive fireman, Fairville, N.B., was seriously injured in a very unusual way. The water glass on the boiler exploded and the shattered tube flew, one piece striking with great force in the young man's back, entering on the right side near the border of the shoulder blade, penetrating right through the right lung and then striking a rib.

Archibald McBride, Kingston, Ont., died after a short illness August 6th. He came from Ireland 60 years ago with his parents, settled in Kingston, and has lived here ever since. During that time he was continuously employed by the Richelieu & Ontario Navigation Company, as engineer, serving on all their boats. His last boat was the "Corsican," on which he was working till within three weeks of his death. He was a brother of Robert McBride, engineer on the R. & O. steamer "Bohemian," and Samuel McBride, carpenter at the Royal Military College, Kingston.

Four of a gang of 16 men engaged in laying the foundation of a pier of the Midland railway bridge across the Shubenacadie river, Nova Scotia, were drowned August 20th in a caisson sunk to the bottom of the river. It was supposed to be air tight, the pressure of air from a plant on the shore keeping the water out. Through some blunder the safety valves were opened and the air rushed out, and the water rushed in to take its place. The men scrambled for the ladder in the narrow air shaft. Twelve ascended in safety and four perished in the rising flood. Their names were Luke Peters, James Wilkes, William Donegan and James Donahoe, of New York.

William Power, a veteran shipbuilder, died in Kingston, Ont., August 29th, after a prolonged illness. He was 78 years of age, and was born in Prince Edward Island. He was engaged in shipbuilding at Quebec, Montreal and Kingston, and many famous craft were of his handiwork.

Three research scholarships of £150 a year, tenable for two years, have been granted by the Exhibition of 1851 Commissioners to W. B. McLean, McGill University. Scholarships have been continued for a second year to W. G. Smeaton, Toronto University, and E. H. Archibald, Dalhousie University, Halifax.

W. F. Pike, M.A., Ph.D., for twenty years professor of chemistry at Toronto University, has resigned, and will remove shortly to England, where he has purchased an estate. He had a private mechanical laboratory, which he equipped at an expense of about $20,000, which was acknowledged to be the most perfectly appointed machine shop in Toronto.

While raising one of the trusses for the roof of the new Methodist church building at Fergus, Ont., John Moffat, contractor for the woodwork, was almost instantly killed. The truss was being hoisted with block and tackle, and was almost at the required height when one of the guy-ropes broke. Mr. Moffat saw what had happened, and was running to avoid the falling timber, when he was struck between the shoulders and died almost immediately.

Marine News.

P. Griffith, St. James street, St. John, N.B., boat builder, has received an order from the Fishery Department, Ottawa, to build a 20 foot gasoline launch, for use at the biological station, St. Andrew's, N.B.

A despatch from Halifax, N.S., states that the barque "Strathome," Maitland, N.S., now at Cork, Ireland, has been sold on foreign account for $14,000. She was built in 1883, and is 1,098 tons register. This is said to be the fifth large Nova Scotian ship sold within a month to Italians. Within the past twelve months there has been a demand for wooden ships of this class, and prices have advanced materially.

There is considerable speculation going on in marine circles over the rumor from Ogdensburg that in all probability the five large steamers of the Ogdensburg line will be made passenger boats by the opening of next season. Plans, it is said, have already been approved of. This, if it goes into effect, will give Chicago direct communication with the lower lakes.

The Allan Line steamship "Sicilian" has been launched. The "Sicilian" is of 5,000 tons, and is especially intended for freight service, but will have accommodation for about 60 first cabin as well as for a number of steerage passengers.

The Lake Erie Navigation Co., Ltd., $40,000 capital, has been incorporated by E. C. Walker, Walkerville; F. H. Walker and J. H. Walker, Detroit; S. A. King, M.D., Kingsville, Ont.; W. Woollatt, Walkerville.

The item in the estimates of $350,000 for Port Colborne is "on account." The plan now in the department contemplates, the Minister of Public Works states, not only the deepening of the harbor, but the erection of berths and slips for the mooring of ships as well as the construction of breakwaters.

At a meeting a short time ago of the promoters of the Quebec, Hamilton & Fort William Navigation Company it was understood that R. A. Lucas, Hamilton, Ont., would take the place of the late Senator Sanford as one of the incorporators of the company. It is the intention to have two new boats built this year, in readiness for next spring's business.

The R. & O. Navigation Co. made a service test of the speed and coal consumption of the new steamer "Toronto" the other day. The builder's guarantee was a speed of 17 miles per hour on a consumption of 2 lbs. of coal per h.p. per hour. On the test made she attained an average speed of 17 1-3 miles per hour on a consumption of 1.76 lbs. of coal per h.p. It is said that the best record hitherto made by a side-wheel steamer having a triple expansion engine, and showing a like speed, is a consumption of 1.80 lbs.

FIRES OF THE MONTH.

August 1st. Electric light plant, Wolfville, N.S.; damage, $8,000.——August 14th. Monty's planing mill, Roxton Pond, near Granby, Que.; damage, $15,000; insurance, $4,500.——August 14th. Monson & Boright's saw-mill, Magog, Quebec; damages, $5,000; insurance, $1,000.——August 14th. James Robson & Son's tannery, Oshawa, Ont.; loss, $4,500.——August 18th. St. Ferdinand d'Halifax, Que., convent of the Sisters of Charity; damage, $50,000.——August 20th. Ontario Box Co., Hamilton, Ont.; damage, $40,000.——August 24th. Scarfe & Co., Brantford, varnish factory; damaged slightly.——September 5th. Power house of the Niagara Falls Park & River Railway; loss on plant, $75,000; building, $10,000.

THE ASPHALT BLOCK.

BY C. BAILLAIRGE, C.E.

The new asphalt block pavement, so-called, is new to Canada, though known and used in a few places in the United States for some time. It is now being laid along the Grande Allee, or St. Louis road, Quebec, extending from the Gate to De Salaberry street, a run of 3,700 feet; and the width being 47 feet from curb to curb. The area, including crossings, will be some 20,000 yards, which at 25 bricks to the yard (the blocks being 12 x 4 x 4 inches), will require half a million blocks. The writer was not slow to recommend their use; as, before he ever heard of them, he had urged on the city council in his yearly reports, an addition of grit or crushed quartz to the powdered rock asphalt, to suit it to grades where the ordinary sheet asphalt would be dangerous. An English engineer named Livingstone had also, after an exhaustive visit to United States, reported favorably on the use of the asphalt block; his report appearing at length in The London Surveyor, an engineering journal highly thought of by the profession.

The asphalt block we are using is made at Hastings on the Hudson, some 30 miles from New York, by the Hastings Paving Company, 66 Broad street, New York. The block or brick, as it may be called, is made up of some 87 to 90 per cent. of crushed quartz, granite or trap rock, reduced to the consistency of coarse sand or fine gravel, in a matrix or binding mixture of Trinidad asphalt, heated to a temperature of 250° to 300° F., the two thoroughly mixed and forced into and out of steel moulds several inches in thickness to stand the stress, under a pressure of 5,000 lbs. to the square inch. This statement is exact, the writer having visited the company's premises and witnessed the process; while he also saw the paving being laid by the company at 183rd street, New York.

There is no doubt but what the mixture of gritty matter with the asphalt or bitumen is the only thing capable of rendering the material suitable to certain grades of roadway. A portion of 183rd street, New York, falling towards the Hudson, has a grade of nearly 1 in 7 or 8, and will, I believe, prove to be too abrupt a one for such material; granite setts being better adapted to such inclines as in Mountain, Palace, Canotterie, Dambourges and Genevieve street hills, Quebec. Neither is the scoria brick suited to such slopes, as witness the upper portion of Mountain Hill, Quebec, where against the written opinion of the city engineer, they were laid, instead of continuing the stone paving to the north side of the electric railway track, at the corner of the postoffice and presbytery, where the outer rail at curve had to be laid to grade of inner rail at least, and should be even higher to guard against derailment by centrifugal action.

The paving on Grande Allee is laid on a bed of sand about half an inch thick or more, overlying a foundation of 5 inches of concrete. This is laid on the old bottom on which the tamarack blocks were laid some 12 years ago. This foundation is composed of two thicknesses of inch boards at right angles, each to the other. The boards are still in a sound state of preservation, as wood generally remains when removed from atmospheric influences, and especially when in or under water, or in wet or moist soils; while wood laid in dry sand or loam does not endure beyond a few years comparatively. I should have preferred, nevertheless, having the wood removed and replaced by so much concrete; but the extra cost would have been some 25 to 30 cents a yard or more and reasons of economy prevailed, as it was held that the boards having already stood good for twelve years would hold out indefinitely; timber underlying old macadam having been taken up in other parts of the city, which had been there for over 50 years, and still as sound and clear of discoloration as the day it was laid.

The 4-inch concrete, as stated, was laid direct on the wooden flooring, where the height of the electric track allowed of no intermediate material; but where the rails are laid at a higher level to rectify grade of roadway, the concrete is laid on a 2 to 3 inch bed of broken stone—that is, of the old macadam picked from between the tracks and rails and spread over the boards, after removal of the old wooden block pavement—the portion thereof occupied by the tracks having been taken up two years ago, when they were laid, and the levelling made up of broken stone.

And just here it may be well to state with regard to the life of a wooden pavement of round tamarack blocks, that while that laid on the Grande Allee, twelve years ago, as stated, was found to be in a dilapidated condition from dry rot, blocks are now to be found in the sample room, city engineer's office, city hall, Quebec, which on the occasion of laying water and drainage in Couillard street, were taken up after being there for more than thirty years, and which though worn down by traffic some 2 to 3 inches, or whole height of block reduced from 8 to 6 and 5 inches, were found to be, and are to this day as perfectly sound as when laid some fifty years ago. The reason for this is that the Couillard street blocks were cut and laid green, or with the sap in them, and which under the influence of moisture from rain and the subsoil retained their sap, keeping the wood green and wet, and thus preventing dry rot; whereas, due to the grub epidemic of 1885 to 1889, the worm feeding on the needle of the tree, killed the tamarack, and this sapless wood being used on the Grande Allee instead of the live material, decay set in and dry rot ensued. The life of a wooden pavement is quoted at only seven years, except when creosoted or infiltrated with some antiseptic, while I had in my sample room, already mentioned, specimens of Australian hard woods, "Tallow" wood, "Mahogany," "Blue Gum" and Jarrah, which to test their comparative endurance under similar circumstances of traffic and exposure, were laid in one and the same street at Sydney. They were taken up after being there eleven years, and show only from ⅜ to ⅝ of an inch reduction in height during the interval, and are still absolutely sound to the very heart, though slightly discolored.

Returning now to the asphalt block, which may either be laid on a bed of sand overlying the concrete, as stated, or preferably on a coating of half an inch of cement mortar; the blocks are laid close jointed, and are well fed to the layers, at the rate of 10 to 15 yards per man per hour (100 to 150 yards per day of 10 hours), but exclusive of closers along curb stone, which require another man or two to cut them to length and lay. The overlap of the brick as laid in New York is 4 inches (1-3 of the whole block), and thus the opposite joints occur at only every third course; but as laid here, the lap is 6 inches (half of the block), the joints thus breaking at every second or intermediate course instead of at every third, engineers differing as to which is preferable. The whole is intelligently carried on under the foremanship of — Watson of New Haven, on recommendation to E. Parent, the contractor, by the Hastings Company. The next operation is ramming down, which is done by two men with a heavy beetle (some 90 lbs.), while a third drags a half-inch plate of steel about 10 inches wide and a foot and a half long, thus always embracing more than a brick in length and two in width, and this is moved backwards and forwards along the pavement in a way always to overlap the last portion receiving the impact or the already consolidated surface.

Following this is the sanding of the joints; for though the blocks are said to touch, there are always interstices of 1-16 to ⅛ of an inch due to roughness of surface, which allows fine dry sand to percolate the joint and fill it. This sand filling was a matter of anxiety to me, as I feared that during rainy weather water might get at the foundation layer of sand and cause the blocks to settle; but no such settlement has occurred anywhere, even after a continuous and heavy two days rain. This non-percolation of surface water into the joints between the bricks I attribute to the bricks' antipathy for water, the oily and greasy nature of the bitumen being antagonistic; or may be water percolates the broader of the joints to a certain depth only, due

to the repulsion referred to, and then acts as a bridge over which the rain water passes on and down the roadway.

When thoroughly sanded, or supposed to be, to all appearances, the paving is opened to traffic. Then a slight tremor of the bricks causes the sand to settle in the joints and the sanding process is repeated to satiety; the sand requiring to be screened fine and absolutely dry (sun or fire dried), without which it will not run into the narrower interstices. It is said, though I was not long enough in New York to notice the thing, that under traffic the edges or arris of the brick gives, due to its plastic nature, and that thus the joint becomes filled in and absolutely impermeable to water.

The cost of the blocks is some $80 per 1,000, delivered at the mill or factory. Thus for transportation to Canada, some $2 per ton has to be added for freight, or $17 per 1,000, the blocks weighing about 8½ tons to the thousand. Again, there is 20 per cent. duty to pay, a toll at Rouses' Point of say $1 to $1.50 per large load, wharfage, harbour dues, etc., cartage to site of paving at say 100 blocks or 4 yards sup., per cart load (1,700 to 1,800 lbs. with us). Now add taking up and removing old pavement, grading, levelling, concreting, sand foundation and laying, and a minimum is arrived at, allowing 10 per cent. profit, of about $3.37 per yard sup. of finished paving; while the tenders for the work ranged up to $4.27 per yard.

Certain precautions are to be observed in the delivery or rather before delivery, or until the blocks have sufficiently cooled down to allow of handling, piling and rough usage in barging and unloading. The bricks to prevent sticking or adhering should be sanded between the layers, and especially on board the barge, where during the hot weather of July and August, and due to superincumbent weight, they are liable to cling together, but can be easily separated with the chisel and hammer. I have also found some of the blocks (very few) to be slightly curved, as if under pressure of overlying load, urged to hug the curved outline of the containing vessel.

The blocks, to save handling and hauling, are piled along the sidewalks on either side. It requires about three or four laborers, according to width of street, to keep the pavers or layers supplied. The brick cuts well, and square, and easily under a blow or two of the hammer, with a chisel 4 inches wide on edge, or wide enough to cover the whole breadth of block.

Between the track rails a row or course of bricks is first laid longitudinally within the rail on each side. This border course is laid to enter an inch, or as far as it will go under the upper flange or projecting head of the rail; tilting it the while to about the camber required (a quarter of an inch), when four stretches just fills the remaining space between the opposite border courses, and the underlying sand bed is, by the use of a mold or template run along the track, resting upon the rails, cambered up in a way to cause the paving between the rails to crown at level, or a quarter or half inch over it, as may be desired; while the border courses so tilted and put in under the top of rail afford the space necessary for the car wheel flange to run in; and again, the sloped groove or depression thus left along the rail, instead of being square, which would catch and hold the wheels of vehicles, allow the wheel to move out sideways without, as in the case of the square groove, tending to haul the paving after it.

Where the fish plates and connecting wires occur (at every 30 feet or length of rail), some of the border bricks inside the rail have to be cut longitudinally, which is easily and neatly done by jumping the chisel along the brick, back and forth, as in splitting a stone parallel to its length, or along the line of proposed fracture.

When the roadway is double tracked, the space between the tracks is filled in flush with top of rail, or, as outside the tracks, a quarter of an inch higher to allow of settling by ramming and under traffic; and as laid here, it takes just three and a half bricks or stretches to reach from rail to rail. This space is also cambered up by a sand template to half an inch additional above the concrete; as any pavement laid flat always looks hollow, and any such hollow in a roadway looks as bad as would a hollow floor or deck, instancing at the same time a want of forethought by the engineer or architect against settlement. To ensure uniformity of curve or camber in cross section of roadway from the curb to curb or curb to rail, when the paving goes on along one side of the street, while the other remains open to traffic, the best, easiest and quickest mode is to measure down from a line held taut across the roadway and resting on curb and curb or curb and rail. It requires two hands to hold the line, but where only one is available, the string at one end can be tied to a peg or to a brick left hanging in rear of curb stone, or in rear of rail before the track is paved or sidewalk laid. This line is successively held at distances of 3 to 4 feet along the roadway—when ordinates or vertical offsets are measured down from it to level of top of concrete—the ordinate along the rail being 4½ inches, or the thickness of the brick plus that of the sand-bed (less, if you wish, a quarter of an inch to allow for settlement by ramming and traffic); at or along the curb, the ordinate is say 9 to 10 inches, including depth of paving and height of curb there; over half way or thereabout (the eye will do) between these extreme points another or third offset is taken, and two more, a fourth and fifth at points again half way (by eye) between the others.

To regulate height or level of pegs to be driven for top of concrete, Mr. Watson has an ingenious mode of offsetting by means of a stick with a notch in it at 4½ inches from level of string, one at 9 inches, and three others at intermediate heights as required and calculated in advance, or measured from a template cut to camber of roadway. He then sets and drives his peg home, or until the top of it is just at proper level to suit offset. These five offsets have of course to be repeated for as many pegs on the other side of the roadway, when in turn that side is being paved, and the paved side handed over to traffic.

To form the sand-bed, strips or templates ½-inch thick are laid at distances along the road of 8 to 10 feet; when two men, one at each end of a straight edge, move it and the sand with it along the templates in a direction parallel to rail and curb and back and forth until the sand is worked down to proper level. I had omitted to say that the paver or layer, instead of, as usual, standing on the unpaved portion, keeps on the portion already laid; as standing on the sand-bed when prepared as above stated would altogether jeopardize the regularity of the work.

This asphalt block pavement is certainly an improvement on the sheet asphalt as far as durability is concerned, it being 4 inches thick, while the sheet is but one to one and a quarter inch. Again, the grit in it suits it to ordinary grades where the sheet would prove slippery and dangerous. Neither will this asphalt block be suitable for heavy traffic or for quick or steep grades or inclines, where nothing but granite setts should be used. The sheet has been laid, against my advice, in such narrow and trafficy streets as St. Paul and St. Peter, Quebec, where on account of wheels travelling constantly in same line, the asphalt will soon be worn into ruts and hollows. The sheet is suitable for residential streets, and especially where there are no rails, as in some of the streets at Westmount, Montreal, where, after, they say, nine years laid, it shows no sign of failure; but in St. James, Notre Dame and other streets, where the traffic is comparatively heavy and tracks exist, the asphalt begins to give a quarter of an inch at a time along the rails under the erosive action of the wheels of vehicles, and then it goes on crumbling, a fraction of an inch at a time, until wide ruts are formed, which have to be repaired.

The Hastings Company also manufacture hexagonal blocks for sidewalks. They make them about 2¼ to 2½ inches thick, which is too heavy and expensive. I have advised the company to reduce these to 1¾ inch, or even 1½ inch, as sufficiently thick to stand foot passenger traffic for years to come. We are about laying a quantity of sidewalks in Quebec with these, which on account of the greater measure of grit in them will prove preferable to the "mastic," as laid hot and rolled or smoothed with wooden pallets. The latter becomes somewhat disagreeable to walk on during hot weather, and especially while the sun shines hot upon it, when it almost instantaneously softens to the consistency of putty or of soft or kneaded clay puddle, and the foot actually sinks into it, perceptibly, or say a sixteenth of an inch or so, though it immediately hardens again the moment the sun is obscured.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports from Great Britain of interest to the metal trades in July, 1898-99, and the seven months ending July, 1898 and 1899:—

	Month of July.		Seven Months to July.	
	1898.	1899.	1898.	1899.
Hardware	£2,190	£1,695	£12,502	£11,145
Cutlery	11,301	3,497	30,798	29 617

SAND FILTRATION OF PUBLIC WATER SUPPLIES.*

BY R. S. LEA, ASSOC. M. CAN. SOC. C. E.

(Continued from last issue).

The layer of gravel serves to support the sand and to conduct the water horizontally to the under-drains. The excessive thickness used in some of the old filter beds is not at all necessary, 12 or 15 inches being quite sufficient. It should consist of three or four layers of graduated sizes, the top one being fine enough to support the sand without any liability of the layers getting mixed. Around the openings into the underdrains the separate stones should be carefully placed so as to avoid any possibility of movement when the water begins to flow. If necessary the gravel must be thoroughly washed before being put in place.

In arranging the underdrainage system of a filter, which includes the gravel bed, the object to be aimed at is to cause the water to sink vertically through the sand, and as nearly as possible at a uniform rate in all parts of the bed. In order to effect this it is evident that the resistance to horizontal motion in the underdraining system must be everywhere nearly the same. Attempts have been made to calculate the proper size of the underdrains, using formulae for the flow of water through gravel and sand of various sizes. A discussion of the matter will be found in the Report of the Mass. State Board of Health for 1892, and also in Allen Hazen's book on the "Filtration of Public Water Supplies," pp. 32-41. With round tile drains, and a daily filtration rate of 2.57 million gallons per acre, Mr. Hazen suggests the following limits to the area which pipes of the different sizes should be allowed to drain:

Diam. of drain.	To drain an area not exceeding	Corresponding velocity of water in drain.
4 inches	290 square feet.	0.30 ft. per sec.
6 inches	750 square feet.	0.35 ft. per sec.
8 inches	1,530 square feet.	0.40 ft. per sec.
10 inches	2,780 square feet.	0.46 ft. per sec.
12 inches	4,400 square feet.	0.51 ft. per sec.

and a cross-sectional area for the larger and main drains of at least 1-6000 of the area drained. With the rate mentioned this would give a maximum velocity in the drain of 0.55 feet per second. These underdrains are variously constructed of open jointed channels of stone or brickwork, or of tile pipes with perforations or open joints. There is no advantage in spacing the laterals more than about 16 feet apart, as the extra quantity of coarse gravel necessary would cost more than the saving in the pipe. In some filters the underdraining has been accomplished by means of a double bottom of open brickwork supported on arches or other arrangements of the same material. The lateral drains usually rest upon the bottom of the basin, but the main drain is often placed lower. If the top of the drain is higher than the coarsest layer of gravel, that part should be closed to prevent the entrance of the fine gravel. In several of the old filters vertical ventilating pipes extend from the under drain above the surface of the water on the bed. These are for the purpose of allowing the escape of air from below, so as not to cause disturbance by passing through the sand. They are not used in the latest filters, as it was found that they were of no advantage, but rather a source of trouble, through the formation of channels between them and the sand, which allowed water to pass without filtration.

The basin which encloses the filtering materials must of course be water-tight; and in that respect the same care must be experienced in its design and construction as would be necessary in the case of any reservoir for holding water. Its depth will depend upon the thickness of the bed and the height to which the water is to be allowed to rise, but does not usually exceed 10 or 12 feet. The bottom is usually level, or perhaps with slight depression for the lateral drains. The walls may be either vertical or sloping, depending upon the material used. Taking into account the necessity of uniformity in the filtration rate at different points of the bed, vertical sides are probably preferable to sloping. Local circumstances will as a rule, determine the best method of construction and the material to be used. The latter may include stone masonry, brick, concrete, earth embankments, puddle, etc. Concrete is a very satisfactory, and in most cases an economical material to use for any part of the structure.

If a roof is required it should consist of groined arches, supported on pillars, preferably of brick. Care is necessary to obtain a solid foundation for the latter, as the form of roof will not admit of much unequal settlement. A good plan is to form the bottom of flat inverted arches, which will give a firm and even support for all the pillars; and the lateral underdrains will then lie along the hollows midway between the rows of piers. With a roof of this kind, vertical side walls will be more economical than sloping ones. But the plane surface between the wall and the bed must be broken by projections, in order to prevent the liability of unfiltered water passing along the junction; which remark also applies to the piers. It is to prevent this same contingency that the gravel layer is only carried to within 2 or 3 feet of the walls, its place being filled by the sand which here composes the whole depth of the bed. Around the inlet and outlet chambers there should be no gravel within 5 or 6 feet of the walls.

Manholes must be constructed in the roof for the admission of light and air. Also a "run" for entering and removing the sand scrapings, etc. With piers spaced 14 or 16 feet on centres a light and strong roof can be built of concrete at a very moderate cost. When the roof is finished it is covered to a depth of two or three feet with earth surmounted by a layer of loam, which may be seeded down or laid out in flower beds, etc. For open filters the sides may be of earth embankments, made water-tight by a layer of puddle or concrete. If of the former, a paving of brick is necessary, which must be of sufficient strength to withstand the action of the ice where it is exposed.

Before proceeding with the methods of operating a filtration plant we will discuss it with reference to these important features, the inlet, outlet, underdrains, etc. With a given flow of water through the bed, the vertical distance H represents the head required to force this quantity through the surface film, the sand, gravel and underdrains. It is variously termed "loss of head," "head on the filter," "filtering head." The depth of water in the majority of European filter beds is usually from 3 to 4 feet, with the full depth of sand. In some of these filters it was allowed to rise and fall according to fluctuations in the removal of the effluent. Such variations in depth, however, are found to have an injurious effect upon the surface layer, and on the efficiency of the filtering process; in the newer plants, therefore, they are provided against by an apparatus on the mouth of the inlet pipe, by which the water when it reaches a certain height automatically closes the inlet. These consist usually of some form of balanced valve worked by a float. In connection with an open filter, such an arrangement must be protected from frost. The inlet opens into a small chamber at the side of the bed, from which it is separated by a wall. The water flows over the wall on to the bed, and is prevented from disturbing the surface of the sand by paving it for a short distance from the chamber. Sometimes the water enters by overflowing an open masonry channel extending across the surface of the bed. The loss of head, corresponding to a given rate of flow of water through the filter, will depend upon the extent to which the surface film has formed, and the friction in

*From a paper read before the Canadian Society of Civil Engineers.

the sand, gravel and underdrains; but under any given conditions it varies (within practical limits) directly as the rate. In some of the old filters, the outlet was connected directly to a clear water basin, or pump well; and the difference in level between the surface of the water in the filter and of that in the well was, of course, equal to the loss of head. Fluctuations in the draft upon the well produced corresponding fluctuations in the filtering head, and therefore in the rate, which was thus automatically adjusted to the demand. In others, however, some sort of apparatus was placed between the filter and the clear water basin by which the rate could be kept constant. This is now considered to be of the greatest importance for the reason that bacterial tests of the effluents have shown that marked deterioration invariably follows fluctuation in the rates. This is probably caused by the mechanical disturbances produced in the sand-bed and surface film. For details of such tests, see Report Mass. State Board of Health for 1894.

In the newest plants, therefore, some kind of an arrangement is always provided for the regulation of the flow. Since the rate varies directly as the loss of head, it is immaterial which is regulated. Some of these devices, therefore, regulate the flow directly, while others accomplish the same result by the indirect method of regulating the loss of head. In order that the former may be kept the same from one day to another, the latter must be gradually increased as the period of service of the bed extends, so as to correspond with the increasing resistance of the surface layer. This is effected automatically in the device which was designed by Lindley for the filters at Warsaw. The apparatus is contained in a water-tight chamber, connected on one side with the filter, and on the other with the clear water basin. The rate at which the water can pass from one to the other depends upon the depth to which the slits in the sliding pipe extend beneath the surface of the water. This is adjusted by weights at the other end of the chain which passes over a pulley. Thus the rate can be kept constant; and as the resistance of the bed increases the level of the water in the chamber will automatically adjust itself to produce the necessary differences in level or loss of head.

In the method of regulation devised by Gill for the Tege works of the Berlin water supply, the outlet from the middle chamber is through a weir; and the depth of water on its crest, and, therefore, the discharge, is indicated by the height of the float read on the scale. This is kept constant by means of the gate. The corresponding loss of head is shown by the difference of the readings on another scale. Keeping the water in the filter always at the same level, a constant rate can only be maintained by the gradual falling of the level in the right hand chamber and a consequent wider opening of the gate.

As to the limit beyond which the loss of head should not be allowed to go, the general opinion seems to be that it should not be greater than the depth of water on the bed, though the Lawrence experiments have not shown any bad effects from exceeding this limit. As a general thing it may be stated that, everything else being equal, the higher the rate the poorer the quality of the filtrate. But with fairly low rates this deterioration is slight, so that entirely satisfactory results can be obtained with rates up to 3 or 3½ million gallons per acre per day. Probably higher rates could be safely employed if very great care were exercised in the operation of the filter. The relative effects of high and low rates from a financial point of view are discussed further on.

When the clogging of the filter bed has become such as to require a loss of head greater than the prescribed limit, the inlet is closed and the water allowed to drain away until it has sunk some distance below the surface of the sand. When this has become sufficiently firm, workmen enter the bed with planks wheelbarrows and broad flat shovels. With these they carefully remove the suraice layer and pile it up in little heaps, which they afterwards remove with the barrows. The depth removed varies from ½ to 1 inch, and averages about 8-10 of an inch. The surface of the sand is then raked to loosen up the packing caused by the boots of the workmen, and after smoothing down any irregularities the planks are removed and the filter is ready for another period of service. The refilling begins from below by admitting through the underdrains filtered water from another bed in action. The object of this is to drive out the air from the pores of the sand, where its presence in the form of bubbles would cause considerable unnecessary friction. When the water has risen a few inches above the surface of the sand, the lower connection is shut off, and the refilling is completed by means of the surface inlet. Before filtration proper begins the water should be allowed to stand on the bed for several hours; or the first million gallons or so should be wasted. The amount wasted can be reduced by beginning the filtration at a low rate, and gradually increasing it to the maximum. When the scrapings have reduced the sand-bed to the minimum allowable thickness, the total amount removed, which has in the meantime been thoroughly washed, is replaced at one time. Before doing so the surface of the permanent layer, which is never removed, should be loosened up by being spaded over to a depth of six inches or so. If this is not done, there is a liability of sub-surface clogging at its junction with the clean sand. When the filter is started again, it is, except for the permanent layer, in the condition of a new filter, and so requires extra care in operating it, and the filtrate should be wasted for a much longer time than is required after the scrapings. Piefke of the Berlin waterworks places this period at six days. Considering the labor necessary, and the time the bed is out of use, this replacing of the sand is an expensive operation, and should not occur oftener than can be avoided. In most plants the usual period is about once a year.

Sometimes it is possible to obtain new clean sand at less cost than is necessary to wash the old. But this is rarely the case; hence an important part of the equipment of a fair-sized filtration plant is the apparatus for the washing of the sand. The simplest of the methods employed for this purpose consists of a broad shallow box, which is set in an inclined position. The dirty sand is thrown into this box, and a jet of water played upon it from a hose. The water overflows from the lower end of the box and carries the dirt with it. This is continued until the water runs off clean. The more elaborate methods employ mechanical means to force the water through the sand. Drum-washers, operated by horse or steam power, are largely used in Germany. They are set in an inclined position, and the sand, with streams of water playing upon it, is forced from the lower to the upper end by means of revolving spiral blades. Various other methods more or less on the same principle are employed.

The "Ejector" washer is probably the most efficient of all the methods employed. It consists of a series of conical hoppers arranged in a row. At the bottom of each hopper is an ejector through which a stream of water passes under a pressure of 15 or 20 lbs. The dirty sand is thrown into the first and largest hopper. From this it is ejected through a vertical pipe into a trough, from which it falls into the next hopper. Here the same thing occurs; and the process is repeated until the water, which is continually overflowing from the hoppers, comes off clear. The whole arrangement must be enclosed in a masonry pit, from which the dirty water is conducted by drains. Six or eight hoppers are required for each machine, which will have a capacity of from 5 to 6 cubic yards per hour. Sand washers of this type are used in the new filters at Hamburg, and are to be used in the plant now under construction at Albany, N.Y. Details of the latter are given in Engineering News, February 10, 1898. The volume of water required in sand-washing varies, according to the method used, from 12 to 20 times that of the sand; the ejector machines apparently requiring the most. The question of cost will be referred to under maintenance.

(to be continued).

The annual summer class in practical surveying in connection with the faculties of applied science of McGill University, began September 1 Carillon, P.Q., is the headquarters of the class this year, and here a series of practical surveys of prospective railways and a continuation of the partial survey of the Ottawa river are being carried out. Upwards of forty-five students, who intend entering upon the courses of architecture, mining, and civil and electrical engineering, are attending the class, which will continue until the session of the Faculty of Applied Science opens. C. H. McLeod, professor of surveying and geodesy; J. G. G. Kerry, lecturer in surveying, and R. S. Lea, assistant professor of civil engineering, are in charge of the work of the class.

Price Bros. & Co.'s saw mill at Amqui, Que., was burned down Sept. 5. The loss will amount to about $100,000.

Abraham Leyer, contractor, of Montreal, has assigned at the instance of Ovid E. Galarneau, with liabilities of about $20,000.

Bylaws to raise $18,000 for a new central school and to raise $4,000 to extend the waterworks system were both carried in Owen Sound recently.

The industries at Deseronto, Ont., are in a very flourishing condition, both the cement works and the new charcoal iron smelter being ordered many months in advance.

Darling & Pearson, architects, Toronto, have been asked to prepare plans for a large hotel in Muskoka, Ont. This hotel will accommodate 500 people. Hamilton capitalists are interested.

The flour mill and shingle mill of Mills Bros., Merrickville, Ont., was destroyed by fire Sept. 5th. The flour and oatmeal mill belonging to H. Easton was also burned, and Watchorn & Co.'s woolen mill was damaged.

Inspectors Noxon and Christie, and Architect Heakes of the Ontario Government staff, are preparing plans for the reconstruction of the Penetanguishene Reformatory into an asylum. The Government has decided to build a new reformatory in Oxford county.

A bylaw was passed at Vancouver, B.C., recently, giving council power to raise a loan of $150,000 for the purpose of extending and improving the city sewage system. At the same time a bylaw to raise a loan of $20,000 for the purpose of acquiring certain lands fronting on English Bay for a public bathing beach and recreation grounds was lost.

The city of Winnipeg has decided to purchase a softening plant for its new waterworks, the plant to cost $17,430 and the installation work $12,500, or a total of about $30,000. The Pittsburg Testing Laboratory, Pittsburg, Pennsylvania, has been awarded the contract for the plant by the fire, water and light committee subject to the approval of the council.

The Ottawa Electric Company has forwarded to Ald. Campbell, acting Chairman of the Civic Railway and Lighting Committee, the following letter, which sets forth the liabilities which the city will have to assume in case of its purchasing the entire plant and equipment of the company: "In compliance with your request I beg to submit the following to enable you to arrive at the amount that the city would be required to assume to take over the business, franchises, etc., of this company, as set forth in our letter of April 27th last. I might add that the figures are taken from our statement of April 30th last, the date of last closing of books:—Capital stock, fully paid up, $765,000; debentures bearing interest at 5 per cent., $320,000; accounts owing, bills payable, $155,940.41; total, $1,241,740.41. I might further add with reference to the item of $155,940.41, that this is about offset by such assets as accounts due to the company, merchandise, stores, etc., on hand. Trusting that this information is satisfactory. (Signed) D. R. Street, Secretary-Treasurer."

WANTED—Young man familiar with installing and repairing electric recording meters. Give particulars of experience. Only hustlers and first-class penmen need apply. Advancement if satisfactory. Address "WATT," Canadian Engineer, Montreal.

WANTED—A First-class Mining Foreman, who has had experience in Galena, Zinc and Silver Mining. Send references and rate of wages expected to P. W. RESSEMAN, 31 Central Chambers, Ottawa, Ont.

FOR SALE

A good Water Power, 500 horse, situated one-half mile from railway, every facility for making siding to power. Address
J. D. THEUNISSON, Cookshire, Que.

—Dr. Andrew MacMeans, of Mexico, a native of Toronto, and a graduate of Trinity University, was in the city recently, spending a few days. Chatting with a Toronto World reporter, Dr. MacMeans said: "I paid my first visit to Mexico ten years ago, and was highly pleased with the progress that country was making, in fact my expectations were surpassed. The vast improvement Mexico has made in the last quarter of a century is almost phenomenal. Twenty years ago there was hardly a railroad, to-day the country possesses over 12,000 miles, and 18 miles of street railway. He further states that the exports of Mexico are the imports of Canada, and the imports of Mexico are the exports of Canada. There is a very great hatred in Mexico for the United States, and everything coming from that country and Canada should profit by this.

—The discovery of the extent and importance of the hematite or limonite deposits in the Michipicoten district seems to promise an enormous development in the iron smelting industry of Ontario. A realization of the immense area and valuable nature of the deposits has been obtained by the receipt of a 43 lb. sample of brown hematite at the Bureau of Mines, accompanied by an explanatory letter from Prof. A. P. Coleman, Provincial Geologist, who has been spending some time in the Michipicoten region. The ore specimen in question contains 60 per cent. of iron, and it was taken from a deposit on the claim of Mr. E. V. Clergue, of Sault Ste. Marie, which is about ten miles north of Michipicoten Post.

ACETYLENE... THE FUTURE LIGHT

THE PERFECT LIGHT for Public Buildings, Offices, Stores and Dwellings.

The Kerr Acetylene Generator

Patented in Canada, Great Britain, United States, France and Germany. Other Canadian and foreign patents pending.
The only perfect apparatus for the generation of Acetylene Gas from Calcium Carbide. Neat, compact and durable.

SIMPLE, SAFE AND RELIABLE

No Valves or complicated Mechanism to mystify and confuse. No Copper, Brass, or other dangerous element used in its entire construction. Write us your requirements and obtain prices.

KERR ACETYLENE GAS GENERATOR CO.
Box 24, NIAGARA FALLS, Ont.

Water, Article IV.	151

For THE CANADIAN ENGINEER.

WATER, ARTICLE IV.

BY W. M. WATSON.

The readers of the Canadian Engineer would understand the subject discussed in the present paper better if they will refer to the articles published in the issues of June, 1897, and of May and June, 1899. In the articles named, I tried to explain how necessary it is to be careful to lay down water mains straight, parallel, and carefully graded, having cutoff and washout valves properly placed, so that every section can be well controlled and thoroughly emptied and washed out, when required. Also, that the arrangement of street mains should be such, that when all are in full working order, the water the street mains contain is always on the move, and that in no part of the system can the water be motionless for days together.

During the fifteen years I have been in Canada, I have observed that waterworks are usually laid on what European engineers call the temporary system, that is in a zig-zag or snake fashion, laying them over hills and dipping the pipes down under valleys and gullies or culverts, paying no regard whatever to the depressions made in the pipes, that will form receptacles for dirt and poisonous matter, or to the air pockets that will hinder the flow of water and cause water hammer and damaging commotions to exist in the pipes, which start leakages and cause over 100 gallons of water to be pumped per head of population per day in Canadian waterworks, when the quantity actually used does not amount to over 40 gallons per head per day. In fact, as far as I can make out, the health of the public, who have to drink, wash, and cook, with the water carried to them by the street mains, receives very scant consideration, and the fearful cost of repairs and management, after the construction is completed, appears not to weigh one feather weight, I am told on all hands that the country is rich, and can stand it, though I know by experience that my taxes alone are nearly as much as both my taxes and rent were together when living in Great Britain I also know that the state and local bodies have mortgaged the property so well that our very clothing fits as if they are in the grip of the money-lender, yet money is wasted on public works just as if it were as plentiful as sand. The purest water can be fouled and badly contaminated during its passage through the water mains to the consumer, by allowing it to have a sluggish flow, and stand motionless for long periods in the pipes; also by allowing the minute particles of vegetable or other foreign and objectionable matter to remain in the pipes, and cause to incubate and multiply, at the rate of, often, millions an hour, poisonous microbes, which afterwards find their way to the taps and get mixed with the people's food. Experience has proved that all such objectionable matter lies in deep depressions, or is forced to the dead ends, and such street mains as are extended the furthest from the intake end of the supply. On that account it is absolutely necessary that washout valves be provided at such points of the water mains, so that the pipes can be thoroughly cleaned about once a month, without wasting much water. Some two years since, I saw in the newspaper that the Toronto analyst had been analyzing the city water, drawn from taps near the centre, and he reported the result to be good. On the same day, I was engaged unstopping a blocked water service in one of the side streets, about two miles west of where the analyst got the water he analyzed. On cutting and dividing the pipe, I found a frog's leg, a few small bones of a fish and some vegetable debris. Afterwards I allowed the water to run to clear it, and the quality that the pipe delivered was far from being fit for use for domestic purposes, and the analyst would certainly have said the same had it come under his notice. All the houses in that street are subject to periodical stoppages, on account of the water main in the street being dirty, and no proper means to clean it out being provided. The water at the intake pipe of the city of Toronto is excellent, but the distributing mains appear to have been laid without any thought of cleaning them out.

There has been said sufficient to show how the health of the people largely depends on the laying of the public water mains and service pipes, and may pass on to the costly damages and inconvenience of frozen

water mains and service pipes which are the outcome of poor construction. I have heard people say that freezing of pipes cannot be avoided, but I do not believe such statements, and if reasonable care is observed, there need be no difficulty of that kind. Since 70 per cent. of the water pipes laid never freeze, then why cannot the balance of 30 per cent. be made to resist severe weather. In several newspapers we have read during the last very severe winter that a fire occurred in a town and the firemen were badly hampered because the fire hydrant was frozen. After large sums of money have been spent to ensure security, the article is useless at the very moment its services are necessary. The citizens are living in false security, and their property may be all consumed and even their lives may be sacrificed because it takes time, a long time, to thaw out the fire hydrant before it can be used to quench the fire, and in that case the coroner would say that it was accidental death and no enquiry necessary, when the fact of the case would really be that the person had come by his or her death on account of the carelessness or want of knowledge of the person who set the hydrant. If the party who was responsible for properly fixing the hydrant were committed for manslaughter, there would be very few frozen fire hydrants. Every winter a large number of families suffer, because the private pipe supplying their dwelling is frozen solid, and to relieve them and thaw out their pipes small boilers on wheels are supplied, probably by the ratepayers, and a staff of men takes them from house to house, and thaws the pipes out by dividing the pipe at some convenient point, and working a small copper tube into the interior of the affected pipe, and blowing in steam, until the blockage is removed; but if the pipe fitter has laid the pipe in a snake fashion, and the small tube cannot be forced round the bends, then the services of the steam boilers are useless. We should insist that work be done by persons who thoroughly understand their business, and make them responsible for the work they do, or have a fully-qualified official to inspect the work and pass it, and thus avoid the necessity of thawing appliances, and the heavy expense of repairing damages done by frost to pipes containing water.

Perhaps a few suggestions and some practical examples of how to ensure pipes from freezing and the causes of freezing may be interesting. Water attracts frost, as well as other things, and the slightest dampness will carry a current of frost down to a metal pipe. By placing an open vessel of water in a room it will attract and absorb the frost, and in this way frost can be kept out of cellars.

By keeping this in mind when laying pipes and fixing hydrants, we may prevent the risk of freezing if reasonable judgment and care be afterwards observed in the management. I believe brass and copper will convey and carry frost along quicker than other metals; this is proved, because it is found that in most of the street mains that freeze and crack, the freezing first began at the brass bend, screwed into the crown of the main pipe, and attached to the private service pipe, and when water once begins to crystallize, it increases the crystallization right and left in the main pipe quickly, drawing the frost by way of the brass bend, similar to the tree getting its nourishment through the small rootlets; on this account we should endeavor when fixing water pipes containing water to disconnect the pipe from frost currents in a similar way, that electricians prevent electricity from being wasted or coming in contact with foreign bodies. This may be done in various ways, first by encircling the metal pipe with stagnant air completely void of circulation, because air is an excellent non-conductor; second, by burying in pitch, rosin, brimstone or wax, or covering the pipe with an air-tight stocking of rubber, gutta percha or dry paper with a waterproof coat of varnish on the outside, to prevent it becoming damp. If a pipe is properly insulated it will not freeze. Another important point is not to fix a pipe in a position where a strong current of air, however small the current may be, can strike it direct, especially at a bend or coupling; for instance, a house pipe is often brought up through the kitchen floor from the cold basement; if the hole in the floor is a little larger than the pipe, the chilled air will rush through the aperture round the pipe, and freeze it. Pipes will stand a considerable amount of cold without crystallizing the contents, if the air that surrounds them is nearly motionless. They always freeze first where the currents of air are the most rapid, however small a stream the current may be; so if it is possible to lay a main or a service pipe so that it cannot be approached by dampness, or where a circulation of air cannot come in contact with it, then it must be safe from frost. Some engineers will not allow the filling over a water-pipe to be pounded down solid, except the traffic of the road demands solidity, because the air between the particles of earth placed loosely over the water main forms a non-conductor, and cuts off the current of frost from descending to the pipe. Even in well pounded earth, that covers the water mains, there is some air, and no doubt it prevents the frost from descending to the pipes a little, and together with the heat that is absorbed from the earth that is attacked with frost by the lower stratum immediately under the frosted surface, is no doubt the cause why the dampness in the soil cannot convey the current of frost down to the main water-pipes if laid at a suitable depth.

It is unwise to allow a metal pipe containing water to touch other metal or damp stone or brick, if such metal, stone or brick communicates in any way with the cold atmosphere outside, because such metal will convey the frost similarly to a wire that conveys electricity. I think that the custom of fixing a bent brass union on the crown of a water main, to deliver a private supply, might be done away with, with advantage, and in the place of tapping the pipe at the crown, the pipe main might be tapped on one side, and in place of using copper bends and connections, annealed or malleable iron fittings should be used, because they cannot attract the cold so quickly as brass, and it is often the case that the water in the mains is constantly on the move forward, therefore cannot readily be attacked by frost; while the water in the brass bend and service pipe only moves when water is drawn into the house, and the contents of the pipe being afterwards motionless, is easily crystallized, and then starts the water in the main crystallizing, and in that way great mischief is done. This method would lower the house service connection as much below the crown of the water main, as the brass bend extends above the water main, under the present rule,

which would be right, because the house service needs more protection than the water main. The objection that the services would break away from the main, on account of expansion and contraction, when iron or brass pipes are used for service pipes, can be overcome by using two English slow bends, keeping them sufficiently apart to allow enough movement to take place that will overcome any expansion or sudden jars that might occur. I also consider the custom of putting a separate service pipe to each house, however small that house may be, or however many small houses are grouped together, is unwise. Water rapidly deteriorates when lying idle in pipes; not only do the friendly microbes in the water die off for want of air, but the water sets up a chemical action with the metal of the pipe. The public health demands that water pipes should, wherever possible, be worked to their fullest capacity, on that account the shortest length possible of service pipes should be used between the street main and the house taps, and as many as can conveniently be served from one pipe should be. Water mains are laid down considerably larger than is needed for domestic or trade supply, as a rule. First, because they may be called upon to furnish several streams at any moment to extinguish a fire; second, because a small cast-iron pipe, placed under a road, is easily broken by heavy traffic passing over it. So we see that it is necessary to prevent the water deteriorating or freezing in winter, to so arrange them that the water at all points is kept, if possible, constantly on the move or circulating, besides having plenty of proper provision for emptying and cleaning them out. There is a service pipe made that will resist frost; also preserve the purity of the water it contains, so far as to prevent the water from setting up any chemical action with the metal. It is made of common wrought iron pipe, having a thick, hollow core, or lining, of pure tin, forced into the interior of the iron pipe, and when forcing the tin into the inside of the iron pipe, a thin rubber cloth or other non-conducting material is placed between the two metals, which insulates the pipe, and prevents the frost having any action on the water it contains. Thus, by using that kind of pipe, the purity of the water is maintained, and the chance of freezing is nil, because it is impermeable to frost, on account of the insulator placed between the two metals, and being lined with pure tin, it is impossible for the water to set up any injurious chemical action.

To make the causes of freezing very plain, I will here relate a few of my own personal experiences. Last winter I was obliged to carry a small water pipe over a roof, and I knew the water would only move about twice each day, and there was a great difficulty presented against the pipe being boxed, so I simply insulated it by placing three-ply rubber hose over it, carefully sealed it at both ends to prevent any circulation of air between the iron and the rubber stocking, and the pipe did not freeze last winter, though the weather was severe and the pipe elevated high in the air. Frost will run down a pipe however well insulated, if the end is exposed to the air, because the frost will travel down the metal forward along the inside of the insulated covering. A customer of mine being troubled with mice, that ran along the pipe line of the water pipe placed under the floor boarding, crossing the joints, from the kitchen boiler to his bathroom, took up a board and encircled the lead pipe with a small piece of tin to stop the mice from passing over the joists alongside of the pipes. The house every year was kept so well heated that the pipe had never been known to freeze, but the small piece of tin made it freeze, at the point where the tin touched the lead pipe, because the tin attracted the little frost that was in the air between the floor and the ceiling, and drew it or focused it on to that part of the pipe that the tin touched, and just there I found the stoppage. Some twelve years since, the Grand Trunk Ry. offices, Montreal, were thrown in the dark by a stoppage of their gas supply. I found the defect was caused by the gas being frozen in the ¾" supply main place in the false roof, where the atmosphere never was less than 50 degrees of heat, therefore nowhere near the freezing-point, but a nail had fallen out of a shingle in the roof, and the heat of the false roof being near the seventies, and the outside being about 30 degrees below zero, there was a rapid ingress of cutting cold air through the small nail hole in the roof, into the false roof, which made a bee line to one of the ventilators placed in the ceiling to ventilate the office below, and on its passage forward it struck the gas pipe about the one-eighth of an inch in width, and crystalized the damp gas at that point, cutting off the supply.

There are many waterworks' fittings that have been carelessly constructed, and to rectify the injury done would cost a great deal, therefore if anyone can come forward and show how such badly-laid pipes can be prevented from freezing and bursting, or show us an easy way of thawing them out when they are frozen, they will be public benefactors and deserve commendation. Town councils and private individuals have had to part freely with their money, and suffer much inconvenience on account of shoddy work that could not be prevented freezing in past years. Electricity, which has a close similarity in its actions and methods of travel with frost, is proved by Professors Wood and Jackson to be able to thaw frozen pipes, small or large,

Hundreds of frozen pipes were thawed out last year by the electrical method, both quickly and at a far less cost than when the dirty steam kettle is used, and I cannot do better than repeat the report Mr. Hiem publishes of Messrs. Wood and Jackson's successful work in the thawing out by live electric currents. The attention of Mr. Wood was drawn to a service pipe that could not be thawed out by a steam boiler, nor could the kink in the pipe that was frozen be reached any other way until warmer weather should set in, so Professor Wood consulted with Professor Jackson, and both together they tried to thaw out the obstinate pipe by electricity, and succeeded beyond their expectation, and then they introduced the system generally. Mr. Hiem goes on to say:

"I will now give you the computations Professor Jackson was kind enough to give me, and which have been verified in the different cities where the conditions were proper and the thawing successful. To thaw out lead or iron services up to one and one-half inch you should use from 200 to 250 amperes; if you are not able to get more than 125 amperes, it will take four times as long. If you use over 250 amperes you are liable to get into trouble by overheating the corporation stop-cock, and all other brass connections. Wrought-

iron pipe must be watched very closely so that the joints do not heat; it has lower resistance, higher conductivity, requiring more current, in order to make more heat, therefore you must watch the unions—that is where the heat occurs. It is necessary to use a source of current which does not affect the electric light lines or other transmission lines; if current is taken from them, danger may result. We have therefore ordinarily used a transformer in the work, but in some cases have used dynamos directly. The source of current should have a pressure of not less than 50 volts. To thaw out 500 feet of a six-inch main in half an hour requires 800 amperes; if you are unable to get more than 400 amperes it will take four times as long, or two hours. Eight hundred amperes will thaw out 500 feet of a 12-inch main in one hour, and a 24-inch main in two hours, etc. The source of current for water mains should have a pressure of not less than 200 volts.

"In preparing to thaw out a water main, connect with two hydrants, winding the wire around the hose nozzle. Screw hydrant nozzle cap up to the wire, making a close connection, commence at open end, where there is no frost, with 800 amperes or less and 200 volts, and thaw say 500 feet at a time. Water should be kept running for at least an hour after the main has been thawed, as it will take that length of time before the water will be slightly warmer. Three-quarter h.p. will thaw a six-inch main in half an hour per foot length; two-tenths h.p. will thaw a one-inch, and one-eighth h.p. will thaw a five-eighths service pipe in half an hour per foot length. There is no danger from electrolysis, on account of the short duration of the thawing process and the ground being frozen. Herewith are the directions for thawing service pipes up to one and a half inches in diameter, which were prepared and sent out by the University of Wisconsin:

" 'The current, which is required for thawing service pipes satisfactorily, is from 200 to 300 amperes. The source of current should have a pressure of not less than 50 volts. Where electric light lines carrying alternating currents are available, a transformer or transformers in parallel may be used as a source of current. It is very important that direct connection of pipes to house lines be avoided on account of danger of fire in which the house is placed by such connection. Where alternating currents are not available, continuous current feeder lines may be used, but these should be entirely separated from the distributing net work of conductors. The way in which the appliances should be connected when an alternating current is used with transformers is as follows: The secondary leads from the transformer should be quite large, such as No. 3 B. & S. gauge, or larger. In making connection to the pipes, one of the secondary leads should be taken into the house, to which the frozen service pipe leads, and contact made at that point by some form of metallic clamp or by simply giving the conductor two or three tight twists about the pipe at any point where the pipe is exposed or at a faucet in the house. The other secondary lead should be put in contact with the water system outside of the house and in a similar manner. This contact may be made at a hydrant or at an adjoining service box, or pipes in a neighboring house. When there are two houses near together, each with frozen service pipes, the two secondary leads may be connected to the pipes within these houses and both frozen service pipes thawed out at once. While the thawing process is going on, the faucet should be open in the house to which the service pipe leads. In one of the secondary leads should be inserted a water resistance, which consists, for convenience, of a bucket of water containing a bowlful of salt, and two sheet-iron or copper plates to which the ends of the severed lead are attached. This serves to control the current. In the primary leads from the electric light line to the transformer it is highly desirable to have a fuse in each lead, and an amperemeter. When all connections are made, the plates are placed in the bucket and are then moved towards each other until the amperemeter records a proper current. If the primary pressure is 1,000 volts and the secondary pressure 50 volts, the current should ordinarily approach 15 amperes. If the primary pressure is 2,000 volts, and the secondary pressure is 50 volts, the amperemeter reading should ordinarily approach 7.5 amperes. Water ordinarily begins to flow in a time not much less than ten minutes, or not greater than one hour. If the secondary current is quite close to 300 amperes the period seldom exceeds one-half hour. The frozen pipes are often split by the action of the frozen water, and these at once begin to leak when the ice is thawed away. For this reason it is desirable to have a plumber where he may be readily called to care for the leaky pipe. The electric current when properly used will not damage the pipes. It is desirable to watch brass and iron connections to lead or iron service pipes, as they sometimes heat on account of poor contact. If such heating appears to be excessive, the current may be reduced with a resulting increase in the duration of time for thawing. After the pipe has been thawed it is desirable to let the water run continuously for a considerable time, inasmuch as the ground all round the pipe is frozen, and the pipe is liable to freeze up again unless the water circulates.' In closing this paper let me give you an extract from an insurance paper, as to the financial result of this discovery: 'A slight estimate of the value of the invention of thawing out frozen pipes by electricity to underwriters can be found from the fact that in 1898, insurance companies paid out nearly $300,000 in losses caused by primitive methods of thawing out pipes.' "

SOUTH AFRICA, ITS PEOPLE AND TRADE.

ARTICLE I.

The obduracy of the Transvaal Boers and their president in refusing to concede the common rights of man to citizens not of their own race, is turning the attention of the civilized world to South Africa and its people. That quarter of the world possesses unusual interest to Canadians, not only from the standpoint of imperial politics, but from its commercial development and its possibilities as a field for Canadian trade. As a prelude to a review of the prospects for Canadian manufacturers and exporters, it will be well for the reader to know something of the causes of the present political complications.

The Cape of Good Hope, though discovered by Diaz, a Portuguese navigator, six years before Columbus landed in America, and though used as a port of call by the Portuguese for a century afterwards, it remained for two English captains, in the employ of the

East India Company—Shillinge and Fitzherbert—to make formal claim of sovereignty in the name of England in 1620. After some rivalry between the English and the Dutch East India companies, the latter, realizing the salubrity of the climate and the fine soil, sent out an expedition under Jan Van Riebeeck—in whose honor the Hon. Cecil Rhodes has recently had a statue erected in Capetown—to make a permanent settlement, and thus began in 1652 the Dutch occupation of the Cape. Little by little the settlements extended back from the Castle on Table Bay, but the life of the settlers was the life of white slaves. They were not allowd to sell their produce to visiting ships, but could only sell to the company at prices fixed by the company. On the other hand, they were not permitted to purchase goods except from the company and at prices fixed, of course, by the company. They and the artisans of the town were, moreover, bled at every turn by the company's officials, and if they attempted to complain to headquarters in Holland their complaints were either suppressed altogether, or the complainants were imprisoned as treasonable persons or otherwise marked out for persecution. The farmers had no title to the lands they brought under cultivation, and were often ejected after working a lifetime upon their lands. They were plainly told that they held their property by grace of the company. Offences, which now would scarcely come under the criminal code, were visited with death in its most fiendish forms. Crucifixion was a common mode of capital punishment, and another was the tying of the victim with his back on a wheel, where his body was broken, and he was left "a prey to the birds of heaven." The rack and the gallows were the common means of punishing slaves. It is not to be wondered at that the Dutch settlers sought to escape this tyranny, and from time to time, in spite of threats and the company's claim of jurisdiction, many got beyond the reach of the company, risking the enmity of the natives in their migration. Thus began the "trekking" of the Boers, which dates back to 1670, and has been a peculiar characteristic of Dutch colonization down to the present day.

During the upheavals of the French revolution, England felt the necessity of possessing the Cape to save her East Indian trade, and after a feeble resistance the Castle capitulated to Sir James Craig in 1795. At the peace of Amiens in 1803 the Cape was restored to the Dutch, but was finally taken in 1806 by Sir David Baird. The first taste of individual liberty and reasonable government enjoyed by the Cape Dutch was given to them by Great Britain. With the advent of Britain at the Cape, the Dutch farmers got their first clear titles to land, they get district courts, where justice was for the first time administered with fairness and without the corruption which had made their masters so odious. The people got their first regular school system, and their first postal system from their new British rulers, who also did away with the system of punishing offenders by the cross, the wheel, and the rack, those brutal instruments of torture being destroyed at the very outset of the British regime.

Such, in a few words, was the contrast between British and Dutch rule at the Cape. It is not to be denied that between the Home Government and the colonial rulers many mistakes have been made in the subsequent history of British rule in South Africa; but more often than otherwise these errors were made through mistaken leniency or mistaken philanthropy towards Boer and native alternately. Perhaps the most unpardonable grievance nursed by the Boers in the present century was the emancipation of the slaves in the Cape Colony in 1837. Many Boers to the present day believe with apparent honesty that a Kaffir has no soul, and class him with the wild beasts of the veldt. While other nations besides the United States have freed the slaves without compensation to the slave owners, Great Britain voted to the slave holders of the Cape £1,247,000. This was only half the amount of the appraisement, but it must be remembered that the slaves of the West Indies and other parts of the empire had to be freed at the same time at a total cost of £20,000,000—an enormous sum for those days—and the sublimest exhibition of the awakening of national conscience ever recorded in the history of nations. Though the Boers must have known from the agitation that had been going on in England for the preceding thirty years that the emancipation of slaves must come, there was a great outcry when the amount of compensation was announced, and, to make matters worse, from their standpoint, a horde of self-appointed agents, working on the circumstance that the money had to be paid in London, bought up the claims of the farmers for a mere song in many cases, and the enraged slave-owning farmers trekked into the interior to the number of several thousand, founding what is now the Orange Free State, the Transvaal, and a portion of Natal. British settlers had anticipated them in Natal, and after some bloodshed and a few years' hesitancy on the part of the Home Government, British sovereignty was proclaimed over Natal in 1843. Although the British Government had warned the emigrant Boers that they were still British subjects, those who settled in the Free State and the Transvaal were allowed to rule themselves. The Free State was indeed taken under British rule for a number of years, but that rule was withdrawn under the protest of a large minority of the inhabitants, and the State was left an independent Republic in 1854. Under the wise and common-sense rule of the late Sir John Brand, who was president for twenty-five years, the Free State has had till now the best relations, almost uninterruptedly, with Great Britain and with her colonial neighbors. There was but one serious difficulty and that arose out of the discovery of the diamond fields on the borders of the State in 1867. The land had been owned and was still claimed by a Griqua chief, named Waterboer, and the British Government having bought up his rights, proclaimed the diamond fields British territory in 1871. The Free State, which had claimed a part of these fields, withdrew under protest, but whatever the merits of its claims they were generously compensated by a payment of £90,000, with which the little State was well satisfied, and with which it built its first railway—a road that stands to-day as the best asset possessed by the State. While the Dutch in the Free State and Natal, as well as in the Cape, have settled down to a fairly general friendliness towards the British, the history of the Transvaal Boers has been marred by a strong and persistent hatred of British Government and people. Peopled largely by the irreconcileables, who had left Natal and the Free State on the advent of the

British, and utterly unable or unwilling to understand the British idea of government of the Kaffir tribes, they have become the Ishmaels of South African civilization —their hand forever against the Kaffirs on the one side and against the British on the other. They have so far failed to see the advantages of the golden rule, or to read the signs of the times, that they have perpetuated the same ideas of lordship as those under which their ancestors groaned in the 17th century. In 1877, when the country was in a state of bankruptcy, Sir Theophilus Shepstone annexed the Transvaal to the British Empire, without active opposition. Whatever may be thought of this step, it was taken with the best intentions, and with the desire to save the Boers from the destruction which would have been their fate at the hands of the Zulu King Cetywayo. The step once taken, it is now generally realized that a terrible mistake was made in giving the country back to what has proved a monstrous system of misrule. The British Government, however, gave the Boers just ground of complaint when it left the Transvaal for three years without any representative institutions, and permitted during that time a military aligarchy, composed of men who gave no consideration to the susceptibilities of the Dutch inhabitants, a large part of whom would have been fairly contented under a system which gave them a voice in the affairs of the country. It was unfortunate that just when the British Government began to be awake to the seriousness of Boer discontent, and were actually considering the constitution framed by Sir Bartle Frere, the flames of rebellion broke out, with the result that the British were defeated in three engagements, through the guerilla tactics of the Boer sharpshooters, and then the Gladstone Government restored the republic under that "suzerainty," which has been ever since a source of misapprehension to the Boers.

Before alluding, in our next article, to the present condition of affairs in South Africa, it is worth while to remember this teaching of the past, that wherever the British and Dutch have co-operated either in colonization, in politics or commerce, they have both prospered. The British possession of the diamond fields was the financial salvation of the Free State; and the British operation of the Transvaal gold fields has lifted that republic from commercial nothingness to a state that has become at once the chief power and the chief danger to the neighboring states and colonies.

HUDSONS BAY.

A. P. Low, of the Geological Survey of Canada, has returned to Ottawa, after fifteen months' exploration of Hudson's Bay. Mr. Low left Ottawa in the spring of 1898 for the Atlantic coast, from whence he went by steamer to the eastern mouth of Hudson's Straits, where he took a yacht and explored the coast down to Great Whale river, a part of the bay not previously explored. Several large rivers were discovered, and great quantities of fish were found, especially in the mouths of the rivers. The fish found were Arctic salmon, whitefish, trout and cod. Mr. Low thinks that they are in sufficient quantities to make fishing for commercial purposes very profitable. The winter of 1898—99 was spent in Great Whale river, Mr. Low and his party living in snow houses. There was not much work done during the winter, as there was barely six hours' sunlight a day; but during the past summer a very large tract of country inland was explored, and some valuable mineral discoveries made, of which details will be given in his report to the Government, which will be made at an early date.

GREEN GRASS GROWS ALL AROUND PETROLIA.

A wail has gone up from Petrolia, Ont., because the Imperial Oil Co. has removed everything pertaining to the oil industry from Petrolia to Sarnia, Ont. As the mouthpiece of the local sorrow says, the "oil wells are there yet." But that need not comfort the town too much, because these wells can only be pumped when the Imperial Oil Co. requires oil, and when the well-owners are prepared to take the price the company feels prepared to pay. When everything has been got on a business basis, the company will pay only what is good for it, and those who know the Standard Oil Co., know what that is. When the people of Petrolia, Ont., refused to bonus the Bushnell Oil Co., some few years ago, they were unaware that the Standard Oil Company then promised that grass would grow in the streets. They did not know, perhaps, that the Bushnell Oil Co. was then, as the Imperial Oil Co. is now, one of many nice little properties which are owned by the Standard Oil Co. In the meantime the grass is beginning to sprout, and the Standard Oil Company monopolizes the oil business of Canada.

—Occasions have been numerous in Canada where one town has had to call upon another for assistance in fire-fighting, and frequently engines, etc., are sent from one town to another. It has been found that in some such cases the borrowed apparatus was entirely useless because the hose couplings were not of uniform size, and therefore they could not be used in conjunction with the apparatus already on the ground. This should be remedied.

THE COMPRESSIVE STRENGTH OF CONCRETE AS DETERMINED BY TESTS MADE AT McGILL UNIVERSITY.*

BY W. B. ANDERSON, STUDENT CAN. SOC. C.E.

Concrete, especially in the construction of piers and foundations, is coming every year into more extensive use. It is therefore desirable to determine its strength, and more particularly the resistance to crushing, as it is to a compressive force that it is most often subjected. The results of very few tests with this end in view are given in any of the treatises on concrete or building materials, or in the engineering journals. A few results may be found, but they are scattered and very irregular, and little information can be obtained from them. During the past three years a few tests have been carried on by the students of civil engineering at McGill University. The first series, two years ago, was to determine the effect of different percentages of water upon the strength, and the best percentage to use. This was found to be about 20 per cent. of the sand and cement. Last year tests were made comparing the strengths of concretes made respectively from an English Portland and a German one. This year tests were made upon sand cement in order to compare it with the Portlands, and also to determine the best proportions in which to mix it in making concretes. This cement was "Cathedral" brand sand cement, made by the "St. Lawrence Portland Cement Co." of Montreal. It is made of equal parts of Portland cement and kiln dried pump sand. These are run together into a revolving cylinder half full of flint pebbles, where they are thoroughly mixed and ground to an impalpable powder.

*From a paper read before the Canadian Society of Civil Engineers.

The conditions under which the tests were made this year were the same as those of the first series (published in paper No. 117, Trans. Can. Soc. C.E.), except that the blocks were made 9 x 9 x 12-in. instead of 12-in. cubes, as the cubes were found, in some cases, to be too strong for the testing machine to break. The blocks were tested with their long edges vertical, and rested on a steel plate which was on a ball and socket joint, the plate above the block being fixed. Sheets of rubber were inserted above and below the block to give a more uniform distribution of the load. The blocks were allowed to stand in the moulds for about two days, and were then removed and placed in water, where they were kept until the time of testing. The results of all the tests made in 1898, and the more striking ones of other years, are here presented in tabular form:

RESULTS OF EXPERIMENTS ON THE COMPRESSIVE STRENGTH OF CONCRETE.

		Mixture.					Breaking Loads lbs. per sq in.				Relative Costs.	
No. of Tests.	Date of Test.	Cement.	Sand.	Broken Stone.	Percentage of Water.	Weight in lbs. per cu. ft	One week	Four weeks.	Two months.	Proportion of mortar to broken stone.	Relative amounts of cement.	First Assumption.	Second Assumption.

Brand of Cement—*German Portland "Hemmoor" Brand. **English Portland "Anchor" Brand. †Sand Cement "Cathedral" Brand. Blocks marked thus (x) remained unbroken under a load of 1,050 lbs. per square inch.

Column 13 shows the relative quantities of cement in the different mixtures, and some attempt has been made to estimate the cost of the different mixtures on this basis. The relative costs are compared on the following two different assumptions:

First assumption—Column 14 shows the relative costs if it is assumed that the sand and stone can be secured on the spot and their cost ignored. The cost of different brands of cement is taken as below.

Second assumption—Column 15 shows the relative costs of the different mixtures and brands on the following assumed costs per cubic foot of materials

English Portland	53 cents.
German Portland	50 cents.
Sand cement	45 cents.
Broken stone	8 cents.
Sand	2 cents.

The cost of labor is not taken into account, as it will be the same in every case, and these costs can at best be only a rough approximation.

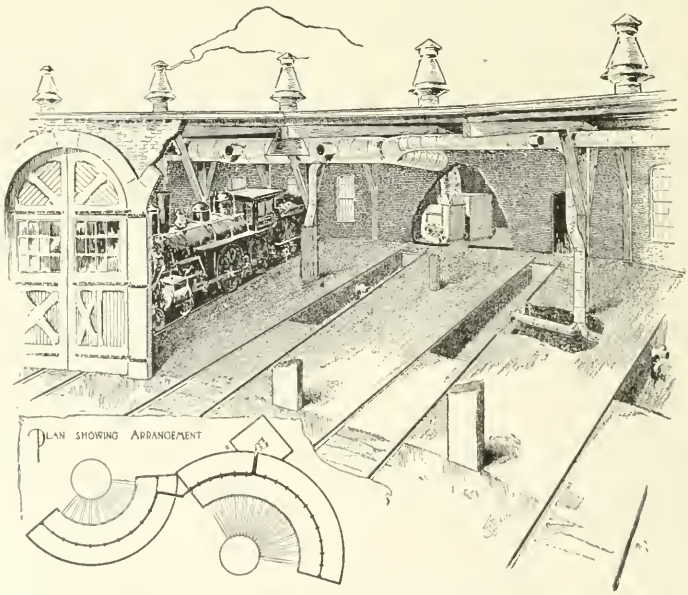
The main requisite for an economic and good concrete is to have just enough cement to completely surround every grain of sand, and just enough of this mortar to fill every interstice between stones. Column 12 gives the proportion of mortar to stone, and it will be seen that with each different mortar the strength increases as the proportion of stone increases, or as the volume of interstices between the stones decreases, because the mortar is not so strong as the stone. The strength also increases with the richness of the mortar in cement, so that the strongest concrete will be one with very little sand and a great deal of stone. Those with the 1-1 mixtures of mortar are very much stronger, though also more expensive than the others. The sand cements are found to be weaker than similar mixtures of Portlands by from 12 per cent. to 40 per cent. The manufacturers claim that with a mortar, such as a 1-10, with a great deal of sand, this cement is stronger than the Portland. This remains to be determined. If the concrete is desired to have very great strength, a Portland cement and a rich mortar might be used, but if weight is the main consideration, with only moderate strength required, a concrete of sand cement will be much cheaper and quite efficient. Of course, much cheaper mixtures than the ones tested can be made, but they will be weaker accordingly after a certain limit is passed, which limit has not been reached in these experiments. One of the cheapest and a fairly strong concrete is No. 23. This mixture would seem the best to use if excessive strength were not required. The loads given in the table are the actual crushing loads. The blocks showed cracks or signs of failure before this load was reached, but it was thought better to make the comparison on this basis. For purposes of comparison it is best to take the results of the four-week tests, as the concretes then show more uniform results than at one week, and the two-month tests are not complete. These tests are still very incomplete, and it might be profitable to make further tests with concretes containing more stone. The strongest of the sand cement mixtures is No. 26, and with this rich mortar it looks as if it would stand a good deal more stone, thus increasing both the strength and weight, and reducing the cost. Tests of this nature will likely be carried out at McGill University in future years.

—S. T. Bastedo, Deputy Minister of Fisheries, and A. M. Wickens, the inspector of boilers, recently made a test of the tug "Gilphic," which the Ontario Government has purchased to be used as a patrol boat on Lake Huron and Georgian Bay waters.

VENTILATING AND HEATING ONE-STORY BUILDINGS.

So far as their construction is concerned, the simplest of all structures requiring ventilation and heating are one-story buildings, such as mills, shops and exhibition buildings. But no other form of building has so large an amount of wall and roof space per cubic foot of enclosed space, or such high and extended rooms; in fact, such a building, as a rule, forms only a single room. As a consequence the most efficient system is necessary; it is not alone sufficient that the apparatus shall be large, to allow for the excessive heat loss from the building, but, above all, the arrangement of the distributing ducts must be such as to most economically utilize the heat supplied; for underheating at the floor and overheating above is one of the most natural consequences of an imperfect system of distribution. Under such circumstances the apparatus itself is frequently condemned as having insufficient capacity, when the trouble lies entirely in the manner in which the heated air is delivered to the building. In buildings of this type the principal provision is to be made for the heating, for the occupants are generally separated, and the air supplied for heating will answer all the requirements of ventilation. But it is nevertheless necessary that they should be provided with fresh air in sufficient quantity. One of the inherent virtues of this method of heating is that it ensures such supply. As the air provided is generally in excess of that required for ventilation, increased economy can be secured by using over again a portion of the previously heated air. This may be done by arranging dampers or doors so that part of the air entering the heater is drawn from out of doors and part, or, if desirable, the whole from the room. In fact, in the ordinary manufactory the common practice is to nominally take the entire air supply from within the building. This does not result, as might be supposed, in a total lack of ventilation, for a very considerable amount of outward leakage takes place through the walls and around windows and doors. Sufficient, indeed, to cause a similar inward, but imperceptible, leakage at other points in such quantity as to result in a comparatively frequent change of air within the building. One of the greatest difficulties in a building of this character is to heat it rapidly in the morning, after it has cooled during the night. No other system can so completely and rapidly meet this requirement as that here presented. When it is desirable, the engine may be run slowly all night and the building maintained at a moderate temperature. The exhaust from the engine being used in the heater, no expense is entailed for motive power.

Chicago, St. Paul, Minneapolis & Omaha Railway Co., Roundhouse, East St. Paul, Minn., shows that the proper heating of a roundhouse presents a double problem, for not only must its temperature as a whole be kept uniform and sufficiently high, but provision must be made, where heavy snow storms are prevalent, for rapidly melting from the running gear of the locomotive the burden of snow and ice with which it is so frequently encumbered when first returned to the roundhouse from a long run. The general method of solving the problem is made evident in Fig. 58. An overhead system, with hot air discharged toward the walls, serves for the general warming, while special pipes, to be used when desired, conduct large volumes of air to the pits, where it is well distributed beneath the locomotives.



Chicago, St. Paul, Minneapolis & Omaha Railway Co. Roundhouse, East St. Paul, Minn.

POWER.*

BY P. TROWERN.

At our last meeting I drew attention to the power of the steam boiler, not the engine. The boiler is the place we gather the force, power or energy together, and from thence lead it into the engine, to turn our shafts, pulleys, belts, mills and pumps. I will again repeat what I told you about the steam. It is not the water that gives the power, but the fire gives the heat to the water, which becomes a medium and expands, so that one cubic inch will become one cubic foot, or one cubic inch will expand to 1,728 cubic inches (one rule says 1,680 cubic inches, another says 1,700 cubic inches, and another says one cubic foot or 1,728 cubic inches), at 15 lbs. pressure. It is very clear that the power is in the heat alone, which is embodied in the water we call steam and power in the boiler. I have laid before you some rules. They have been making boilers by them. Yet none seem to be up to the scientific mark nor satisfactory.

I would like some of your readers to take up the subjects I have mentioned in friendly talk. The Centennial Exposition standard is that the evaporation of 30 pounds of water per hour from feed water, having a temperature of 100° F., into steam having a pressure of 70 lbs. per square inch is equal to one horse-power. The American Society of Mechanical Engineers' standard is that the evaporation of 34½ lbs. of water per hour from and at 212° F. is equal to 1 horse-power. With a 60-inch tubular boiler, properly made, well set, and carefully fired, from 8 to 10 lbs. of water to 1 lb. of coal should be made into steam of 60 lbs. per square inch. This would depend on the quality of the coal and the temperature of the feed water. Practically no more coal will be required to convert 1 lb of water into

*From a paper read before the C. A. S. E., No. 18, Toronto.

steam at 80 lbs. than it will at 60 lbs. Theoretically it will require 4-10 of 1 per cent. more.

When setting boilers in brick work the practice is to rake in the side walls to the shell a few inches below the water-line, and thus limit the heating surface. It is customary in calculating the surface of the shell to consider that two-thirds of it is exposed to the action of the heat. In estimating the heating surface of a boiler, take 2-3 of the outer surface of the shell and the whole of the inner surface of the tubes or flues; reduce the whole to square feet, divide by 12 for two flue boiler, and by 15 for multi-tubular boilers, the quotient will be the horse-power; from 14 to 18 square feet per horse-power. Eight months ago I had a new boiler given to me with a shaking grate. It very soon ceased to move, and became expensive to be used, both in labor and coal. I have removed the grate and put in one, cost about one-half, pulled out the brick bridge, filled up a big pit behind called a combustion chamber, and enlarged the ash pit. The new bars are 5 feet long by 6 inches wide, herring bone draught; and instead of the bars dipping behind 3 inches I have raised them ¾ of an inch per foot, and the brick bed behind to the end of the boiler one foot short, with the same grade; or in other words, the front of the boiler is 20 inches above the bars, and the back end of the boiler is 10 inches above the brick bed, or wall. This end I call my bridge, because as the flame passes from the brick bed around the end of the boiler to enter the tubes it drops the ashes and soot into the pit, to be drawn out through the ash door behind. Building the brick work like this gives the inspector an opportunity of seeing the boiler from one end to the other, and also to crawl through to examine the bottom of the boiler from end to end. During my past forty years of building in boilers in this style, I have not had a blister, nor defect in the row of rivets, because the intense heat of the fire is spread from the front end to the back end, much alike, with a better draught. Since I have changed the bars and the bridge we have done the same amount of work with less labor and coal. I have 22 boilers like this one, built in, now in good working order. One of these was made with Low Moor iron by Mr. Currie for me, in the year 1862, and is in good working order now. Some time ago I conceived the idea of knowing the difference of the pressure of the steam on top of the water in the boiler and that below the water. I fitted a pipe to the blow-off pipe at the back end, and put a gauge on it at the same level as the gauge in front, which was pointing to 60 lbs., the one at the back pointed to 52 lbs. I tested both the gauges. I have said the boiler was 5 feet diameter, 14 feet long. I then thought if the exhaust steam could be brought back to the boiler without losing much heat or pressure it might be of great use in saving the use of steam in the future, for it appears other power is going to take its place.

I am now about to ask each one of you to assist me in solving a great question. In almost every country in the world men have been trying to make the most of the heat in the steam by pushing it into a condenser to heat the water, to feed the boiler with it as well as to avoid the pressure of the atmosphere against the exhaust steam when leaving the cylinder. For many years I have been engaged in heating a building with hot water and returning it again to the boiler. This is the question: How can we do it with steam in the boiler at 60 lbs. and cylinder at 50 lbs ? What arrangements with valves or any other plan could be adopted to save the heat by getting the steam back again into the boiler without condensation or losing its heat more than in passing from the cylinder to the boiler ? I will now turn your attention to liquid air. Liquid air is ordinary air as we breathe it compressed to 1-781 of its normal bulk, or in other words 1,781 feet are pressed into the space of one foot, and reduced to a temperature of 320° below freezing. It has an expansive force of 2,000 pounds to the square inch; it has a latent force of 100 times greater than steam, and as a motive power it is thought that it may be proved to be superior to any known force in or of nature.

—The Rideau Lakes Navigation Co. is a new organization of Ottawa, Kingston and Perth capitalists, who will in the course of a few days make application for letters patent. The capitalization will be $100,000. The company proposes to operate a line of steamers between Ottawa and Kingston by the Rideau River and lakes, and take steps to develop the country as a resort for tourists.

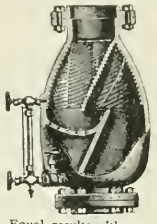
THE AUSTIN STEAM SEPARATORS.

The illustrations accurately detail the construction of the horizontal and vertical separators. By the use of the Austin separators, impurities of whatever nature are, its makers claim, removed from exhaust steam. The steam is immediately given a circular travel (the acknowledged principle for perfect separation) and all impurities or condensation which may escape the corrugations are extracted by centrifugal force aided by gravity, while passing over the separating plate. The steam is in continuous contact with separating surfaces during entire passage through this machine, the makers state. Grooves draining corrugations lead to separating plate, which convey to bottom chamber all impurities, which are discharged through outlet as shown. All practical users of steam power appreciate the importance of condensation being removed from live steam, as when saturated with water there is great danger of cutting the edge of valves and ports, which is not only injurious to the engine, but causing leakage and improper distribution of steam,

"HORIZONTAL"

Can be connected either right or left hand.

"VERTICAL"



Equal results with upward or downward flow of steam.

makes the expense of operation far greater than should be with steam perfectly dry; if there is much condensation in live steam it is apt to cause wreckage of engine by forcing out cylinder head and damaging the working parts. With wet steam proper lubrication of cylinder is not obtained, on account of the hot water neutralizing the action of oil in cylinder and permitting its cutting, practically having the same effect as if no oil was used. Wherever live steam is carried long distances a large element of condensation takes place, which will be entirely eliminated, the makers of the Austin separator believe, by use of their machines, averting all possibility of accident from water in cylinder, the engine working much smoother and greater power obtained. When exhausting into a tank or open heater or where exhaust steam is used for heating purposes and condensation is returned and used as feed water, the oil in exhaust will not only ruin boiler but cause foaming. By using one of these separators in exhaust steam pipe all grease, oil and other impurities will, it is said, be removed. The Austin Separator is manufactured by the Austin Separator Co., 59 Woodbridge street west, Detroit, U.S.

THE CANADIAN ELECTRIC LIGHT CO.'S WORKS ON THE CHAUDIERE RIVER, QUEBEC.

The contract for the works on the Chaudiere River, Quebec, to supply electric power and light to the town of Levis, was signed a short time ago by John Breakey, president of the Canadian Electric Light Company, and C. H. Deans, president of the New York Engineering Contract Company. The works, which are to be in some respects the largest in Canada, to be completed and delivered within six and a half months. The contract calls for the construction of a concrete dam, 900 feet in length, and bulkheads 100 feet long, bringing the total length of the dam to 1,000 feet. Besides the dam the company will build gates, bridges, earthen embankment, boom and piers, pipe supports, power house foundations and tail race, the whole to be completed and in running order by about the 10th of March, 1900. With this dam the company guarantees to supply a minimum of 5,000 h.p., and Levis and surrounding municipalities will be supplied with electric light and power. At the annual meeting of the Canadian Electric Light Company held on the 27th of June last, the directors in their report stated that they had secured exemption from taxation for twenty years in nearly all the municipalities in which the company will work. Besides this a large number of contracts for the lighting of public buildings and residences in Levis and neighborhood, has already

been signed, the Chaudiere Valley Railway Company is to be constructed and operated with the company's power, and the intention is to construct, as they are needed, other electric railways in the counties of Levis, Bellechasse, Dorchester and Lotbiniere. The plans were prepared by the well known engineering firm of T. Pringle & Son, Montreal. A. R. Henry, M.E., is the electrical engineer of the company.

MINERAL INDUSTRIES OF ONTARIO.*

Summary of mineral production in 1898, with quantity and value of mineral production in 1898, with number of workmen employed and amount of wages paid for labor:

Product.	Quantity.	Value	Employees.	Wages.
		$		$
Building stone, rubble, etc	.....	750.000	1,250	520,000
Cement, natural rock barrels	91,528	74,222	85	23,784
Cement, Portland, barrels	153,348	302,096	220	104,350
Lime, bushels	2,620,000	308,000	548	127,000
Drain tile, number.	22,668,000	225,000	2,622	456,000
Common brick No.	170,000,000	914,000		
Pressed brick and terra cotta, No.	8,969,868	100,344	126	42,580
Sewer pipe	.....	93,717	77	26,260
Pottery	.....	155,000	164	61,000

Totals	.....	7,235,877	7,495	2,464,239

[1] Net tons of 2,000 lbs.

BUILDING MATERIALS AND CLAY PRODUCTS.

Statistics of building materials were not collected for the year 1897, and for that year they are incomplete. The years of depression had seriously affected the building trade, and production fell off steadily for some time. But with the revival there is a brisker demand for building materials, and it is noticeable also that there is a more generous response to the request for statistics.

The total number of men employed in the production of building materials last year was 4,611, the amount of wages paid for labor was $1,168,240, and the value of materials produced was $2,378,611. In these statistics cement is not included. This industry employed last year 305 men, with wage earnings of $128,134, while the value of the product of their labor was $376,318. The number of workmen employed in brick and tile yards was 2,622, or nearly 800 more than in 1896. Separate statistics are given for pressed brick and terra cotta, and as will be seen there is little sign of revival in the production of these materials. Two or three of the works had been closed down owing to lack of demand for pressed brick, but work has been resumed at one or two of these and it is likely that the output of this year will show an increase. The number of men employed at the quarries last year was 1,250, or 480 more than in 1896. Brick and tile works are correspondingly active, and the output of the yards is but little short of the best year in the decade. The number of men employed at the works last year was 114, being 29 less than in 1897.

The statistics of lime production show an increase in proportion to those of other building materials, and very nearly approach the highest figures of the decade. The number of workmen employed last year was 548, or 118 more than in 1896.

The manufacture of sewer pipe last year gave employment to 77 men, whose aggregate wages were $26,260, as compared with 64 men and $19,600 for labor last year. The value of sewer pipe produced was $93,717, or $20,166 more than last year.

CEMENTS.

Very satisfactory progress continues to be made in the production of cement, but especially the Portland variety of it. There has been substantial improvement in the output of the natural rock cement works during the past four years, but values are not so well maintained as is the case with Portland cement, and the rate of increase is considerably lower in the number of workmen employed, in the amount of wages paid for labor and in the quantities produced. The following table gives the statistics of the industry for the last five years:

Natural rock cement— Schedule.	1894.	1895.	1896.	1897.	1898.
Number of works	5	5	5	4	4
Number of workmen.	63	45	56	70	85
Wages for labor	$13,020	$14,166	$15,200	$21,500	$23,784
Product, bbls	55,323	55,219	60,705	84,670	91,528
Value of product	$48,774	$45,145	$44,100	$76,123	$74,222
Portland cement—					
Number of works	3	2	2	2	2
Number of workmen.	105	129	120	161	220
Wages for labor	$31,858	$46,000	$48,400	$67,560	$104,350
Product, bbls	30,580	58,699	77,760	96,825	153,348
Value of product	$61,060	$114,332	$138,230	$170,302	$302,096

The average rate of wages in natural rock cement works rose from $207 to $315 during the period, and in Portland cement works from $303 to $451, while for both classes of works the aggregate of wages paid for labor grew from $44,878 in the first year to $128,134 in the last, being an increase of 185 per cent. The product of all cement works has grown from 85,903 barrels in 1894, valued at $109,834, to 244,876 barrels in 1898, valued at $376,318, being an increase of 173 per cent. in quantity and of 243 per cent. in value. There has been a slight fall in values per barrel, the average of natural rock being 88 cents in 1894 and 81 cents in 1898, while the average of Portland in 1894 was $2, and in 1898, $1.96. The statistics of Portland cement for 1898, it should be stated, includes 18,400 barrels of Silica Portland, valued at $32,200, which accounts for the apparent fall in value per barrel of Portland. But although the production of cement in Ontario is steadily growing larger, there is no falling off in the quantity of imports for all Canada. The following statistics show for the five years, 1894-8, the values of imports entered for consumption from Great Britain, the United States and other countries:

Year.	G. B.	U. S.	O. C.	Totals.
1894	$182,074	$33,263	$ 68,234	$284,471
1895	135,603	21,103	95,130	251,020
1896	121,125	25,007	107,007	255,020
1897	111,551	45,200	104,081	260,842
1898	100,548	50,855	200,574	300,977

It will be noticed that the trade has undergone a marked change in this short period of four years, the imports from Great Britain having fallen off from 64 to 29 per cent. of the whole, while those from the United States have increased from 12 to 16 per cent. and from all other countries from 24 to 55 per cent. of the whole. Practically all imports except those from Great Britain and the United States come from Belgium and Germany, the former having last year supplied cement to the value of about $150,000, and the latter to the value of about $50,000. The

* From the Report of the Bureau of Mines, Vol. VIII., 1st part, 1899.

amount of duty paid was $124,868.65, being $121,968.58 on Portland, and $2,900.07 on all other kinds. The total quantity imported last year, including what was not entered for consumption, was 1,153,040 cwt. of Portland, and 11,713 cwt. of other kinds.

POTTERY.

The pottery works of the province gave employment last year to an average of 164 men, whose earnings were $61,000. The value of products was $155,000.

PETROLEUM AND NATURAL GAS.

The total quantity of crude petroleum distilled last year was 26,978,977 imperial gallons, worth at the average price of crude $1,122,801. This was in quantity 1,422,386 gallons, and in value $55,753 more than for the previous year. During the first half of the year six refineries were in operation, owned by five separate companies; but during the second half the business was practically in the hands of two companies, viz., the Imperial of Petrolia, and the Bushnell of Petrolia and Sarnia, and it is now in one. The following table gives the quantities and values of distilled products for the years 1897 and 1898:

Products.	1897.		1898.	
	Gallons.	$	Gallons.	$
Illuminating oil.....	10,891,337	1,131,083	12,281,622	1,243,490
Lubricating oil	1,959,810	199,755	2,043,226	202,150
Benzine and naphtha.	949,341	77,340	1,240,967	121,840
Gas and fuel oils, tar..	8,021,633	281,035	8,047,441	286,705
Paraffin wax, candles..	2,139,278lb	88,378	2,616,086lb	116,349

In 1897 the total value of distilled products was $1,777,591, and in 1898 it was $1,970,534. In 1896 the value of distilled products was $832,187 more than the value of crude, being an appreciation by treatment of 74 per cent. In 1897 the appreciation was $710,463, or 67 per cent., and in 1898 it was $847,733, or 75½ per cent. Last year it was supposed that the lower rate of appreciation in 1897 was a result of tariff changes, but this view is not supported by the statistics of 1898. The average rate of wages was lower last year than in either of the previous years, being $482.68 against $540.83 in 1897, and $541.33 in 1896; but no doubt this is a consequence of a closing down of three of the plants in the latter part of last year. The average number of workmen employed at the refineries was 546, and the amount paid for labor $263,546. In 1897 the number was 364, and the amount paid for wages $196,965.70. The proportion of refined products obtained from the crude is shown in the following table for the seven years 1892-98, and indicates in a general way the progress that has been made in the processes of distillation during that period:

Product.	1892. p.c. of crude.	1893. p.c. of crude.	1894. p.c. of crude.	1895. p.c. of crude.	1896. p.c. of crude.	1897. p.c. of crude.	1898. p.c. of crude.
Illuminating oil...	38.67	39.12	41.10	43.31	45.08	42.62	45.52
Lubricating oil....	12.35	12.45	10.91	9.51	9.07	7.67	7.58
All other oils.....	27.34	28.14	30.45	28.07	31.09	35.10	34.42
Totals.....	78.36	79.71	82.46	80.89	85.24	85.39	87.52

In the seven years the increase of all refined products obtained from the crude has been 9.16 per cent., made up of 6.85 per cent. in illuminating oil, and 7.08 per cent. in all other oils except lubricating; in the latter there has been a decrease of 4.77 per cent. The wax product last year was larger than in 1897 by 476,808 lbs., and larger than in 1896 by 1,084,415 lbs. There is perhaps no other industry in the country in which such marked and satisfactory improvement has been made as in the oil industry, and those employed in it deserve great praise for the intelligent methods they have so diligently pursued.

A great deal of exploring and developing was carried on during the year for supplies of crude, and the situation was improved in consequence. A small field north of the London road in Sarnia township has been added to the producing territory. The southern part of the township of Plympton has also given good results, although in these two localities the oil deposit is not quite so uniform as in the old districts of Petrolia and Enniskillen. It was thought last summer that the township of Brooke gave evidence of a good deposit, and quite a number of wells were drilled there; but the supply did not prove to be permanent, and most of the wells have been abandoned. In the township of Zone, near Thamesville, the same experience was realized; several wells yielded liberally when first drilled, but the flow did not last. Bothwell is getting its producing limits as an oil field defined, and during the year its yield was little more than 6,000 barrels monthly. Euphemia and Dawn have each a small field, the area of which is being expanded by exploration. In the old territory, which runs from the southern part of the township of Sarnia in a southeasterly direction through Enniskillen by way of Petrolia, wells may be struck at nearly every attempt. Small detached areas in this region not previously explored give good returns, one of the best being near Oil Springs. It takes time, experience and risk of loss to discover these treasures of Nature's storehouse, but it is not improbable that anywhere throughout the counties of Lambton, Kent and Essex a discovery of oil may be made. A new locality that has recently been attracting attention as an oil field is in the southern part of Dunwich township, in Elgin.

CALCIUM CARBIDE.

For the thirteen months ending December 31, 1897, the product of the Willson Carbide Works Company at Merritton was 574 tons of calcium carbide, valued at $34,440, the average number of workmen employed being 30, and the amount of wages paid for labor, $12,544.62. Last year the product of the works increased to 1,040 tons, valued at $55,976, the average number of men employed was 35 and the amount of wages paid for labor was $16,397.95. The only interruption to operations during the year was caused by a cyclone which swept over the town and destroyed a number of buildings, among them being one of the power-houses of the company. The damage to the power-house was quickly repaired, however, and meantime the mill and furnace were run at a reduced capacity. The demand for calcium carbide continues to be very satisfactory, more indeed than the Merritton factory has been able to supply. But although this is the case the selling price at the works has been reduced by $6 per ton. Further reductions will no doubt be made when larger works are erected, and more experience is gained in processes of manufacture. Important advances are likely to be made during the present year as a result of recent methods and tests.

GRAPHITE AND MICA.

The graphite mine in Brougham township was worked during only six months of last year. In that time 300 tons of ore were raised, valued at $6,000. Ten workmen were employed.

Mica has been discovered at a number of points during the last few years, chiefly in Muskoka and Frontenac. At most of the properties however, operations have not got beyond the development stage, and the returns show that only one of them was a producer last year. The Stoness-Kent mica mine, which is on lot 4 in the thirteenth concession of Bedford township, produced 34 tons of mica, valued at $7,500. From 12 to 18 men were employed. Only small lots were taken out at other locations. Mica for boiler covering is growing actively in demand.

PIG IRON AND IRON ORE.

The following table gives the statistics of the Hamilton blast furnace for the three years it has been in operation:

Schedule.	1896.	1897.	1898.
Ore smelted, tons.....	51,138	37,492	77,023
Scale and mill cinder, tons...	5,883	5,350	8,614
Limestone for flux, tons.....	8,657	9,473	13,709
Coke for fuel, tons.....	30,348	27,810	50,407
Pig iron product, tons.....	28,302	24,011	48,253
Value of product	$353,780	$288,128	$530,780
Wages for labor	$ 47,000	$ 40,000	$ 61,476
Average workmen, No.....	125	130	130

The proportion of Ontario ores used in the furnace last year was 27 per cent. of the whole, being 20,968 tons, whereas in 1897 it was only eight per cent. Two mining companies, whose operations were carried on chiefly in Hastings county, raised during the year 27,400 tons, nearly all of which was shipped to

Hamilton. Its selling price at the mines is given in the returns as $48.875, or $1.78 per ton. At the furnace the value of Ontario ores smelted was $62,904.81, or $3 per ton, which is the same rate as for American ores. The value of mill cinder at the furnace was $17,229.22, of limestone for flux $11,039.44, and of coke for fuel $158,783.22. The total value of raw materials and labor at the furnace was $479,597.64, and the total value of pig iron product $530,789. At the iron mines an average of 100 men were employed whose wage earnings were $26,700, and the value of ore mined, computed at the selling price at the mines, was $48,875.

COPPER AND NICKEL.

There has been a stir in the copper and nickel mines during the past year, and a number of new properties have been developed. Besides the mines in the Sudbury district, several locations north of Lake Huron, in the vicinity of Bruce Mines, have been receiving the attention of prospectors and capitalists. The Joseph Powers Syndicate on the Missisaga river has sunk one or two shafts, the old mines at Bruce Mines have been unwatered with a view to the resuming of operations there, and a new company has been opening up large showings of ore at Rock Lake, in Coffin township (now called Aberdeen). This last venture has been acquired by a syndicate now organized as the Rock Lake Mining Company, with an authorized capital of $1,000,000. The locations are situated about 10 miles north of Bruce Mines station, and comprise an area of 1,400 acres. The vein has been traced on the property for a length of three miles, and samples of float ore may be picked up to the south of it a long distance. Work was commenced in April of last year upon an outcropping of ore about 300 feet above the level of Rock Lake, and two adits 1,200 feet apart have been driven in from opposite sides of the ridge which holds the vein that prove its thickness to be 16 to 17 feet. A shaft is in course of being sunk, and test pits have been dug at various points, which indicate that the vein is well mineralized throughout its whole length. Work has also been resumed on Michipicoten island, where native copper occurs in amygdaloid trap and conglomerate, but although good samples are shown and rich outcroppings have been discovered, enough work has not yet been done for a judgment to be formed of their extent and value. In the township of Garson, about ten miles north of Sudbury, a copper-nickel deposit was opened last year, and a furnace to smelt the ore was in course of construction. North of Markstay station also active development work has been carried on and extensive bodies have been exposed, some of which carry gold as well as copper and nickel. The Canadian Copper Company, however, is the principal operator, and several new mines have been developed by this company. The following table shows for the seven years, 1892-98, the quantities of ore raised and smelted in the Sudbury district, and the per cent. of metallic contents in the ore smelted each year:

Year.	Ore raised. Tons.	Ore smelted. Tons.	Per cent. of metallic contents in ore smelted. Nickel.	Copper.	Cobalt.
1892.....	72,340	61,924	3.36	3.10	.1007
1893.....	64,043	63,944	2.21	2.38	.0800
1894.....	112,037	87,916	2.02	3.14	.0721
1895.....	75,139	86,546	2.67	2.73	.....
1896.....	109,007	73,505	2.67	2.54	.....
1897.....	93,155	96,093	2.68	2.86	.....
1898.....	123,920	121,924	2.28	3.13	.....

The total quantity of ore raised in the seven years was 650,040 tons, and the quantity smelted 591,852 tons. Last year's output alike of the mines and smelters was considerably more than in any previous year. It will be noticed that the increase in ore smelted has been almost steadily continuous from year to year, and while last year's record was more than 25 per cent in excess of the previous year it was nearly 100 per cent. more than in 1892. The percentage of nickel contents is fairly well maintained, but the percentage of copper was higher last year than in any one of the seven years.

The total number of workmen employed last year was larger than in any previous year excepting 1892 and 1894, and the amount of wages paid for labor was larger than in any year excepting the first. The aggregate amount of wages paid for labor in the seven years was $1,929,894, or an average of $489.45 per year; for last year the average was $493.74, which is higher than for any of the other years excepting 1893 and 1896. In the seven years the quantity of ore smelted was 591,852 tons, which on being reduced to matte gave 80,929 tons ordinary, and 4,233½ bessemerized matte, or in the proportion of 100 to 14.38. The estimated metallic contents of matte product in the seven years are 14,852½ tons, or 29,705,000 lbs. nickel; 17,285¼ tons, or 34,570,500 lbs. copper, and 30¾ tons, or 61,500 lbs. cobalt. At the selling price of matte at the furnaces, which is the form in which it is exported to the refineries, the total value of nickel product for the seven years has been $3,294,060, of copper $1,302,805, and of cobalt $14,613, or a total of $4,611,478. The selling value of last year's product was $782,300, the estimated quantities being 4,567,500 lbs. nickel and 8,373,500 lbs. copper. Comparative values of the metallic contents of the matte based on the selling price at the works are given for the seven years in the next table:

Year.	Nickel		Copper		Cobalt	
	per ton. $	per lb. cents.	per ton. $	per lb. cents.	per ton. $	per lb. cents.
1892.....	283.81	14.190	119.90	5.995	436.82	21.841
1893.....	275.08	13.754	80.50	4,025	494.73	24.736
1894.....	238.36	11.918	71.23	3.561	461.54	23.077
1895.....	174.83	8.741	68.02	3.401	.....	.....
1896.....	183.22	9.166	69.94	3.497	.....	.....
1897.....	179.91	8.995	72.75	3.637	.....	.....
1898.....	184.72	9.236	64.02	3.201	.....	.....

These figures show a slight rise in the value of nickel compared with the averages of the previous three years, but a large decrease compared with the first three years of the period. In the case of copper the lowest point of the period was reached last year, although the price of copper had gone up to a point not reached during many years. Obviously the value should be considerably higher than it appears.

GOLD AND SILVER.

Gold was produced last year at 17 locations, but as only four of these have reported an output in excess of $20,000 it will be readily understood that a large majority of them are yet only in the early prospecting stage. The leading ones are the Sultana, the Mikado, the Regina and the Belmont. The Regina however was closed down for five months, during reconstruction of the mill. The Foley was also idle for the greater part of the year, pending a sale of the property in England. In the eastern part of the province the Belmont and Deloro mines promised well at the beginning of the year, but unfortunately the mill of the Deloro was destroyed by fire early in the spring, and a new one erected in its stead was not completed until the close of the year. Both of these mines give assurance of good results for the present year, and in the west the outlook is very hopeful. The following table gives the statistics of gold mines and mills in the province for the five years, 1894-98:

Schedule.	1894.	1895.	1896.	1897.	1898.
Mines worked	4	8	8	9	17
Men above ground	40	126	103	222	290
Men under ground	52	111	86	210	284
Ore treated, tons..	2,428	6,500	13,202	27,589	57,895
Gold product, oz..	2,022½	3,038	7,154	11,412	16,201
Gold value $32,776	$50,781	$121,848	$190,244	$275,078
Labor wages paid..$38,032	$56,234	$91,210	$217,760	$290,010

The total quantity of ore milled during the seven years, 1892-98, has been 116,074 tons, and the value of gold product was $740,587, being an average of $6.33 per ton. This is proof of the low grade character of the ore, but as nearly all of it is free milling, it is high enough to earn a good margin of profit when development is sufficiently advanced to provide an ample quantity to keep the mills running steadily. It will then be possible to select the ore, instead of treating all that comes from the mines. Therefore an increase of average may reasonably enough be looked for, unless, as seems likely, some extensive low grade deposits are worked on a large scale.

THE PRACTICAL MAN.

LUBRICANTS FOR CUTTING TOOLS.

Material.	Turning.	Chucking.	Drilling.	Reaming.	Tapping Milling.
Tool Steel...	Dry or Oil	Oil or Soda Water	Oil	Lard Oil	Oil
Soft Steel...	Dry or Soda Water	Soda Water	Oil or Soda Water	Lard Oil	Oil
Wro'ht Iron	Dry or Soda Water	Soda Water	Oil or Soda Water	Lard Oil	Oil
Cast Iron...	Dry	Dry	Dry	Dry	Dry
Brass	Dry	Dry	Dry	Dry	Dry
Copper	Dry	Dry	Dry	Mixture	Dry
Babbitt	Dry	Dry	Dry	Dry	Dry

Glass.....Turpentine or Kerosene.

Mixture is one-third crude petroleum and two-thirds lard oil. When two lubricants are mentioned the first is preferable. Oil is sperm or lard; sperm is preferable.

To Harden Cast Iron.—Many times it is very convenient to make an article of cast iron that needs to be finished, and which should be very hard. Cast iron can be hardened as easily as steel, and to such a degree of hardness that a file will not touch it. Take one-half pint vitriol, one peck common salt, one-half pound saltpetre, two pounds alum, one quarter pound prussiate potash, one-quarter pound cyanide potash; dissolve in ten gallons soft water. Be sure that all the articles are dissolved. Heat the iron to a cherry red, and dip it in the solution. If the article needs to be very hard, heat and dip the second and even the third time.

Annealing Cast Iron.—To anneal cast iron, heat it in a slow charcoal fire to a dull red heat; then cover it over about two inches with fine charcoal; then cover with ashes. Let it lie until cold. Hard cast iron can be softened enough in this way to be filed or drilled. This process will be exceedingly useful to iron founders, as by this means there will be a great saving of expense in making new patterns.

To make a casting of precisely the same size of a broken casting without the original patterns.—Put the pieces of broken casting together and mould them, and cast from this mould. Then anneal it as above described; it will expand to the original size of the pattern, and there remain in that expanded state.

How to Anneal Brass or Copper.—In working brass and copper, it will become hard, and if hammered to any great extent will split. To prevent cracking or splitting, the piece must be heated to a dull red heat and plunged in cold water; this will soften it so it can be worked easily. Be careful not to heat brass too hot, or it will fall to pieces. The piece must be annealed frequently during the process of hammering.

The Relative Weight of Different Metals.—The weight of wrought iron being 1, cast iron will be .95, steel 1.02; copper 1.16, brass 1.09, and lead 1.48.

Weight of Castings.—If you have a pattern made of soft pine, put together without nails, an iron casting made from it will weigh sixteen pounds to every pound of the pattern. If the casting is of brass, it will weigh eighteen pounds to every pound of the pattern.

A metal that will expand in cooling is made of 9 parts lead, 2 parts antimony, and 1 part bismuth. This metal will be found very valuable in filling holes in castings.

Lead Explosions.—Many mechanics have had their patience sorely tried when pouring lead around a damp or wet joint to have it explode, blow out or scatter from the effects of steam generated by the heat of the lead. The whole trouble may be avoided by putting a piece of resin, the size of a man's thumb, into the ladle and allowing it to melt before pouring.

Glue.—A little powdered chalk added to common glue makes it much stronger; and a glue that will resist the action of water may be made by using skimmed milk instead of water. A few drops of vinegar put in mucilage will keep it from spoiling.

To Sharpen Reamers.—Hand reamers, when dull through wear, should be stoned first on the face of the flutes, then on top of the flutes. The stone should be always held perfectly flat with the face and clearance that the original shape of the flutes may be preserved. End cutting reamers should be first turned on centres with a wheel, and then recleared to insure reaming a hole the same size of reamer. The Norton Emery Wheel Co. makes an emery stone for the purpose, which is well adapted, and is said to give quicker results than any oil stone. The stone should be kept clean by the use of turpentine.

ICE BREAKING.

There was built last year in the shipyards of Sir W. G. Armstrong, Whitworth & Co., an ice-breaking steamer for the Russian Government, designed by Vice-Admiral Makaroff, and her business is to be to keep some of the principal ports of the Baltic open during the winter. From "Engineering" we take the following account of her first voyage:

Admiral Makaroff first met the ice in the Baltic. It was drift ice, apparently about five feet thick, and judging by the report of Mr. Gulston, of Newcastle, who accompanied Admiral Makaroff on his voyage, there seems not to have been the slightest difficulty in getting the "Ermack" through this obstruction, as she went comparatively easy at nine knots, the engines working slowly. Before going into the ice the engines had been slowed down to ten knots, so as to reserve the powers of the engine-room staff for the harder work which was to come. The worst piece of ice which was encountered was estimated at twenty-five feet thick, and the ship went nearly through this formidable obstruction before she was brought up by it. Accurate measurements were taken as soon as possible and the report reads that the field ice was five feet in thickness, the pack on top was nine feet, and there was ice below the field amounting to eleven feet, so far as could be measured, but there may have been more, as there was no means of measuring further below the bottom of the field. It was evident that a large mass of ice had been washed off a shoal and frozen on the field. The worst field ice that they had much of was apparently four feet thick, with snow on top of it. The snow seems to be the greatest impediment to the vessel's progress, as the designers of the ship had always been led to expect. Mr. Gulston reports that twelve inches of snow was a serious impediment, and eighteen inches almost blocks her. This is, of course, on the top of thick field ice. The ice generally in the Baltic seems to have been much more serious this winter than was expected, and it is said to be beyond 1883, which we gather was a record winter. The "Ermack" did not run continuously, but rested at night and started early in the morning, working with the searchlight. There was apparently no difficulty in starting, although the ship had become fast in the ice. Ice anchors were put out, and the vessel was warped backwards from her berth, after which she started without difficulty. One of the most satisfactory features is that she steers, as Mr. Gulston says, "In any way, at any time, in any ice." This has never been the case with any ice-breakers that have previously been built, and is no doubt due largely to the form of the ship, for there is no flat place on her side, either vertically or horizontally, so that unless absolutely frozen in solid she can be given some movement, and can thus be worked loose by her own propellors and by ice anchors laid out. Her arrival at Cronstadt was evidently an extraordinary sight. The ice was about eighteen inches thick, with a good deal of snow on the top, and the ship steamed through this at six and a half knots up to the sea wall and past the battleships. She swung around on the port hand and entered the harbor through an entrance only ninety five feet wide; the ship itself is seventy-one feet beam. She swung once in the inside harbor, and one charge astern put her into her berth alongside the coal store. Some manœuvering trials were made in ice of about two feet to three feet in thickness when the turning circle was found to be about six hundred feet, and there was apparently very little difference in which direction the ship was turned. The effect of the bow propellor was most marked, and it seems practically to be that if the bow propellor is stopped, the ship stops, too.

Mr. Gulston examined the ship both inside and outside, as far as he could, and could find absolutely no sign of weakness. The outer skin has been polished bright where the vessel has been running through the ice; but there is no sign of breakage anywhere. The ice varied enormously in quality. Drift ice was passed through, and appeared to offer practically no impediment; pieces described as quite two to three acres in extent were pushed aside, the ship moving through quite easily. Pack ice with eighteen inches of snow on top, seems to have been the greatest difficulty.

The " Ermack " is 305 feet long, 71 feet beam, and 42 feet 6 inches deep. She is capable of developing 12,000 horse-power, and of making 16 knots an hour. She has four screws, all four bladed, and varying in diameter from 13 feet to 14 feet 6 inches. The blades are enormously thick, and made of very strong cast-steel, are calculated to be brought up by the ice when the vessel is running at full speed without breaking. The draught of the vessel is calculated to be 19 feet, in fresh water, and 25 feet when working in the Kara Sea, with 3,000 tons of deadweight. The screws are arranged, three at the stern and one at the bow.

Reference should be made to the arrangements for coupling up this ship with another or others, in order to make a train of ships for more effectively dealing with thick ice. Although the " Ermack " is so big and strong a ship, there is, of course, a limit to her capacity of breaking up ice, and to the speed with which she could perform the operation. A vessel pushing astern of her would supply additional power to do the work. Forward the stem is set at an angle of seventy degrees from the vertical. So in going through the ice she would slide up, raising her bow, and this would cause the ice to break down. She might, of course, mount the ice until her forward propeller came into contact with it; but, as has been said, this is made of sufficient strength to stand the shock. That, however, is not what is expected generally to occur, as the form of the bow is designed to keep breaking down the ice continuously. Of course this would absorb an enormous amount of power; but if another vessel, either an ice-breaker or an ordinary steamer, were pushing astern, naturally the speed would be increased. Moreover, a vessel not so strongly built as the " Ermack " would be protected by following close behind her. For this reason a recess has been built into the counter of the ship. This recess is designed to take the stem of the following vessel, arrangements being made for lashing the latter in firm contact with the leading craft. It may be mentioned that the " Ermack " has also a specially strong towing windlass abaft.

ACCIDENTS OF THE MONTH.

An explosion occurred in the Blockhouse, N.S., gold mines, Sept. 13th, resulting in the death of one man and the serious injury of another.

S. Gagnon, a young apprentice in Gilmour & Hughson's sawmill at Ottawa, was killed while attempting a horizontal bar act on a fast revolving shaft which turns beneath the mill.

H. Dooley, Division street, Ottawa, 25 years of age, a mill-hand at J. R. Booth's sawmills, while at work, Sept. 14th, was caught between two rolls six inches apart and drawn in front of a five-foot circular saw, and was mangled in such a way as to die shortly afterwards.

J. Benoit, about forty years of age, living at 18a Soulanges street, Point St. Charles, Montreal, was killed instantly at the G.T.R. shops, a short time ago. He was struck violently on the chin and side of the head by some machinery operated by shafting, and his brains scattered.

W. A. M. Pollock, electrician, in the employment of the Almonte, Ont., Electric Light Company, met with a fatal accident, Sept. 18th. While working with a large driving belt he was caught and drawn into the wheels. One arm was torn from his body at the elbow, and he was hurt internally. He died two hours later. It took over an hour to extricate him.

TORONTO EXHIBITION NOTES.

D. K. McLaren, leather belting and mill supplies, Montreal and Toronto, had a fine exhibit of various kinds of belting, and a great variety of textile and other mill supplies.

The Still Motor Co., successors to the Canadian Motor Syndicate had two storage battery vehicles in the Machinery Hall, and one in constant operation through the grounds.

The Royal Electric Co., Montreal and Toronto, had the whole of the eastern end of the central tier of exhibits, where a great aggregation of motors, transformers, dynamos, meters and switch boards were shown. Among these was a 3,000 light machine and a 2,000 light and 1,500-light machine all of which were sold. It was the most comprehensive exhibit in the line of the electric line.

The Northey Mnfg. Co. had a small building all to themselves, near the western entrance to Machinery Hall, where several of their well-known Imperial gas engines were in operation, and attracted a large number of investigators.

The Robb Engineering Co. had an exhibit of the celebrated Robb-Armstrong engines, which are now known not only all over Canada, but in many foreign countries, where they have gained acceptance in competition with the best makers in the world.

The Dodge Mnfg. Co., manufacturers of pulleys, had an imposing trophy formed of their celebrated wood split pulleys, which were also to be seen in actual use on many other exhibits. This company are the largest manufacturers of wood pulleys under the British flag.

A. W. Spooner, of Port Hope, " the handsomest town in Canada, and the only place in the world where Spooner's copperine is made," had a striking display of copperine. The genial owner of this metal reports that it continues to grow in popularity among engineers.

The Northey Mnfg. Co., are showing gas and gasoline engines in great variety. Machinery Hall exhibit contained a combination gasoline or gas engine, which is used for operating a pump. To the right of the western entrance they had a building in which the bulk of their exhibit commanded much attention from the visitors.

Cowan & Co., of Galt, only showed wood working tools although they manufacture the Corliss pattern of engine. They publish a very complete catalogue showing the different styles made by them. Their exhibit comprised 12-in. moulders, planers and matchers, band saw filers and " Clark " pattern band saw set, and one power feed rip saw. The Cowan people are advocates of the fast gear type of machine gearing, and their arguments are interesting and instructive.

Just outside the east end of Machinery Hall was a complete exhibit of road-making machinery shown by the Good Roads Machinery Co., of Hamilton. It consisted of a Champion rock crusher, a road roller, a mud scraper, a road grader and road ploughs. Mr. Challen, the manager, was always surrounded by an interested crowd of enquirers. He reported that the Government of New Brunswick had adopted the Good Roads Machinery Co.'s system, their latest order being a No. 4 mounted crusher, a 12-ton steam roller, a McAdam spreading wagon, and other machinery.

One of the most attractive exhibits was that of the Jones & Moore Electric Co., of Toronto. They exhibited a complete line of electric motors up to 40 h.p., as well as several direct current dynamos, enclosed arc lamps, telephones for private lines, etc. This firm make a specialty of lighting and power plants for factories and mills. Some of the plants on order and installed are: D. S. Perrin & Co., London, 400 light dynamo; N. R. Williams Co., Montreal, 80 light dynamo; Gadsby & McCann, Toronto, 20 h.p. motor; Massey-Harris Co., Toronto, 20 h.p. motor; Meaford Woolen Mills, 80 light dynamo; Toronto Grain and Seed Cleaner Co., Toronto, 20 h.p. motor; McFarland, Gray & Southgate, Toronto, 8 h.p. motor. They now have over 500 machines in daily operation.

In Machinery Hall this year power was supplied to the line shafting and individual machines by different makes of engines. The Corliss type, the well known Wheelock and the Ideal; one of the Wheelock 100 h.p. being the purchase of the Industrial Fair for Machinery Hall. The Still Motor Company exhibited one of their motor carriages, and the company have, owing to the great number of orders, been unable to spend time in preparing exhibition goods. One of the features of Machinery Hall was the Hardill tandem compound engine exhibit. This new engine was patented in Canada in January, 1899. A company has been formed in Mitchell, Ont., to manufacture them. The engine exhibited was 5 in. H.P. and 8½ in. L.P. cylinders, and 7-in. stroke. In January and February of this year Prof. J. T. Nicolson, of McGill University, tested the economy of this engine and made a report on April 14th, 1899, a copy of which can be procured upon request. According to the report the engine showed 21½ i.h.p. working double acting. Prof. Nicolson says: " I am surprised at the economy shown by so small an engine. It is accounted for by the compounding of the expansion and the high speed."

At the close of the Exhibition a number of the exhibitors in the machinery hall met and presented Thomas Eversfield, the chief engineer, with a handsome bedroom suite in oak. The gift was accompanied with an address expressing the donors' appreciation of Mr. Eversfield's attention to the exhibits during the fair.

Rice Lewis & Son, Ltd., of Toronto, are to be complimented on the large and artistic display of parlor mantels, grates, tilings, railings and other interior house fittings. A tiled bath-room and two or three parlors were represented, and each exhibit was in excellent taste. The rooms were filled with an admiring crowd each day, and the display was voted the best of the kind in the Exhibition.

The Mica Boiler Covering Co., not content with having a boiler and a range of piping covered with their mica covering in the Machinery Hall, had their covering placed on several engines in other parts of the grounds where engineers could test for themselves the remarkable properties of mica for this purpose. All the pipes connected with the motive power in the Machinery Hall were covered with this material, which received much favorable comment.

The Luxfer Prism Co. had a long dark gallery built, in one end of which was a swinging window fitted with Luxfer prisms. It was a source of never ceasing wonder to the thousands of visitors here that when the window was closed the whole gallery was lighted from end to end with a soft light, in which the colors of every object could be distinguished; but when the window was opened to the full light of the sky there was comparative darkness through the gallery, and no colors could be made out in the placards on the rear wall. As a means of shedding light in dark places everybody admitted that Luxfer prisms were a remarkable discovery.

LITERARY NOTES

The Daily Review is a new paper, which reaches us from St. John's, Newfoundland. This will be a welcome addition to the journalism of Great Britain's oldest colony in America.

Glaziers' diamonds of every known style and type are illustrated in the catalogue of A. Rudd & Co., St. Helens, Lancashire, Eng. This concern also makes nippers, vises, atmospheric soldering irons, and other tools for the manipulation of sheet, plate and stained glass work. Messrs. W. J. Woodburn & Sons, Montreal, are Canadian representatives.

The interesting history of the "Beginnings of the St. Lawrence Route," by Arthur Weir, B.Ap.Sc., Montreal, which recently appeared in The Canadian Engineer, has been reprinted in pamphlet form. Mr. Weir has gathered a great amount of hitherto unpublished matter in this essay, and has presented it in such an attractive form that many will be glad to have it in this convenient form for future reference. Although the edition is a very limited one the price is only 10 cents per copy.

The Quebec and Lake St. John Railway have published some books descriptive of the scenery on the line of their well known road, which also contain many good illustrations of the sportsman's variety. The names of the books are as follows: "Guide to the Lake St. John and its Tributary Waters;" "Ye Ancient Quebec," and "A Tale of Lake St. John." Any or all of these will be sent to any person interested. Their time tables are original in design, and much more complete in information and description than the ordinary run of railway folders.

Few people, except those who have made a special study of Canadian books, would believe that a mere catalogue of Canadian poets and their works would make a volume of 72 pages, and contain about 500 names. Such, however, is the array of Canadian versifiers presented by C. C. James, the Deputy Minister of Agriculture for Ontario, in a work just compiled by him for the Victoria University Library. Mr. James recently presented the University with what is probably the largest library of Canadian books of poetry yet collected, and this bibliography is his crowning tribute to the poetical literature of the country. It is from the press of William Briggs.

—A steel bridge will be erected over the Pembina River near Riviere, Man., to cost about $3,000. Another steel bridge will be built over the same river 20 miles south of Manton.

QUEBEC ARCHITECTS' ASSOCIATION.

The annual meeting of the Provincial Architects' Association was held in Quebec city, Sept. 23. A. Raza, president, was in the chair, and presented the annual report, which states that the association now numbers 139 active members, of whom ten joined during the year. The meeting elected the following officers for the ensuing year: President, S. H. Capper; vice-president, G. E. Tanguay; second vice-president, Joseph Venne; secretary, G. O. Monette; treasurer, W. A. Doran; council, Messrs. A. Raza, J. S. Archibald, E. Maxwell, A. Chausse, H. Staveley and A. H. Lapierre. The next meeting of the association will be held in Montreal in September, 1900.

THE GREAT LAKES COPPER CO.

Much interest is being taken by everyone realizing the value of the mineral industries to Canada in the plant now being established at Sudbury for treating the nickel-copper ores of that district by the Great Lakes Copper Co., of Sudbury, Ont. The president of the company is Jno. McKinley, 60 State street, Boston, and the superintendent is C. M. Boss. The plant is now in process of construction, and is to a certain extent experimental. The process is being patented in Canada, and when the necessary formalities have been completed this journal will publish a more extended notice of it. The great advantage attained by the use of the process of the Great Lakes Copper Co. is a reduction in the time of ore treatment. In fact it is said that instead of weeks only three days is required to produce nickel of 60 per cent. fineness from the ore.

GOOD WORK APPRECIATED.

The Canadian Engineer has a splendid report in this week's issue of the C.A.S.E. convention held in Berlin in August. The report is very full and accurate, and every engineer should obtain a copy. Mr. Smith, The Canadian Engineer's representative at the convention, deserves credit for the manner in which he looked after C.A.S.E. interests.—The News-Record, Berlin, Ont.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports from Great Britain of interest to the metal trades in August, 1898-99, and the eight months ending August, 1898 and 1899:—

	Month of August.		Eight Months ending August.	
	1898.	1899.	1898.	1899.
Hardware	£2,115	£2,025	£14,617	£13,170
Cutlery	5,043	4,149	35,841	33,766
Pig iron	1,007	1,743	8,113	8,815
Bar, etc.	229	2,880	6,271	10,969
Railroad	—	1,363	6,972	58,591
Hoops, sheets, etc.	12,095	12,852	36,122	68,307
Galvanized sheets	7,270	4,643	39,341	40,117
Tin plates	12,571	20,175	96,169	118,266
Cast, wrought, etc., iron	1,454	7,903	16,662	32,315
Old (for re-manufacture)	—	421	3,574	2,424
Steel	2,542	9,134	35,185	52,760
Lead	3,668	5,111	19,726	32,440
Tin, unwrought	652	1,773	11,875	14,215
Alkali	3,139	2,850	27,558	21,508
Cement	2,671	2,700	14,824	18,939

—A Washington special to The Detroit Free Press says the United States War Department has referred the protests of their Lake Carriers' Association against the construction of the canal through Kent county, Ontario, connecting Lake St. Clair with Lake Erie, to Col. Leydecker, with the request for a full investigation and a report. Col. Leydecker will report both as to the probability that the project will find adequate financial support, and as to its effect upon the level of the lakes, should it be carried out. It seems probable that if it is found that the Canadian project is being seriously considered with any prospect of its being actively entered upon in the near future, the State Department will take the matter up with the Canadian Government on the basis of a proposition to appoint a commission which was earnestly advocated by Col. Leydecker and his colleagues in their report on the Sault power canal.

NICKEL EXTRACTION BY THE MOND PROCESS.*

BY SIR. WILLIAM CHANDLER ROBERTS-AUSTEN.

The rules of the institution provide that an associate shall submit a paper within a year of his election. In complying with this direction, the author was satisfied that no better subject could be selected for consideration than the interesting process which marks an entirely new departure, in metallurgical practice, from the principles which have hitherto guided it. This process depends on the remarkable property possessed by nickel of forming a volatile compound with carbonic oxide, or, as it is called in modern chemical nomenclature, carbon-monoxide. When this gaseous compound is heated to 180° C. nickel is released in the metallic form.

The author was much impressed during a recent visit to Canada with the imperial importance of the great nickeliferous district of Sudbury, Ontario. In view of the magnitude of this deposit, the annual production of metallic nickel in Canada seems inadequate, as it has hitherto not exceeded 2,750 tons. The description therefore of any new process which affords a hope of hastening the development of this remarkable district should prove to be interesting. The deposit itself presents many points of interest. According to Professor Coleman, of Toronto, the nickel ores of Ontario resemble the gold ores of Rossland in British Columbia, as they consist of a mixture of pyrrhotite (magnetic pyrites) and copper pyrites. These sulphides form enormous masses near the margin of large areas of diorite, or weathered gabbro of Huronian age, the amount of nickel contained in the ore averaging between 2½ per cent. and 10 per cent., the lower proportion being the more common. It is worthy of note that pyrrhotine from other parts of the country, found in association with Laurentian rocks, is almost barren of nickel. The importance of the nickel deposits of Ontario may be judged from the fact that, until the mines in the Sudbury region were worked, the world's supply of the metal was drawn chiefly from the mines of New Caledonia, an island in the Southern Pacific, supplemented by the Gap mine in Pennsylvania, and a few isolated mines in Norway and Hungary. The extent of the Sudbury deposits is greater than any of these, and New Caledonia, which belongs to France, is virtually the only rival of Ontario in the production of nickel.

The ore at Sudbury is smelted into a regulus, or matte, which contains between 12 per cent. and 20 per cent. of nickel, and about the same amount of copper, although usually there is rather more copper than nickel. This matte may be enriched by suitable treatment, and is "bessemerized" into a regulus which contains about 40 per cent. of nickel, and is especially free from iron, as the following analyses show:

	I.	II.
	Per cent.	Per cent.
Nickel	40.938	31.35
Copper	45.714	48.80
Iron and (Al_2O_3)	0.405	0.81
Cobalt	0.130	.....
Sulphur	11.900	...

It is unnecessary to give a history of the metallurgy of nickel, but it may be well to state that Chronstet isolated the metal in the year 1751, and that Bergman confirmed his discovery in 1774. The methods hitherto employed for extracting the metal from its ores are very complicated; they have involved concentrating the nickel either as a sulphide (matte or regulus), or as arsenide (speise) followed by either "dry" or "wet" treatment. In the case of certain ores, wet methods only have been employed. The metallic nickel has always to be subjected to a process of refining, mainly, as in the case of cast iron, with a view to separate it from associated carbon.

As regards the process which forms the subject of this paper a few brief historical details may be offered. In 1889 Dr. Ludwig Mond, F.R.S., in collaboration with Dr. Carl Langer, was engaged in working out a method for eliminating the carbon monoxide from gases containing hydrogen which they wanted for use in their gas battery.[2] In attempting to effect this, they were guided by the observation they had previously made that finely divided nickel has the remarkable property of removing carbon from carbon-monoxide at a temperature of 350° C., converting it into carbon-dioxide, while the dissociation of carbon monoxide by heat alone, according to Victor Meyer and Carl Langer, remains incomplete at the high temperature of 1,090° C. In the course of these experiments, which they carried out in conjunction with Dr. Friedrich Quincke[3], finely divided nickel formed by reducing nickel oxide at 350° C., by hydrogen, was treated with pure carbonmonoxide in a glass tube at varying temperatures. In order to keep the poisonous carbon-monoxide out of the atmosphere of the laboratory the gas escaping from the apparatus was ignited. They found to their surprise that while the tube containing the nickel was cooling, the flame of the escaping gas became luminous and increased in luminosity as the temperature sank below 100° C. Metallic spots were, moreover, deposited on a cold plate of porcelain held in this luminous flame, just as spots of arsenic are obtained in applying the Marsh test for that metal. It was also observed that on heating the tube through which the gas was escaping, a metallic mirror was obtained, while the luminosity of the flame disappeared. On examination these metallic deposits were found to be pure nickel. The next step was to endeavor to isolate this curious and interesting nickeliferous compound, by preparing nickel with great care at the lowest possible temperature, and treating it with carbon-monoxide at about 50° C. The amount of the volatile nickel compound in the gases passing through the apparatus was thus gradually increased. The gases issuing from the apparatus were treated with a solution of cuprous chloride to absorb the excess of carbon-monoxide, and in this way a residue of several cubic centimetres of a colorless gas was obtained, containing the volatile nickel compound. By passing this gas through a heated tube the nickel and carbon-monoxide were again separated, and the volume of the carbon-monoxide thus set free was found to correspond to about four equivalents of carbon-monoxide to one equivalent of nickel. By further improving the method of preparing the finely divided nickel, and by passing the resulting gases through a refrigerator cooled by snow and salt, the investigators at last succeeded in obtaining the new compound in a liquid state, and were able to produce it with facility in any desired quantity.

Nickel carbonyl in its pure state is a colorless liquid boiling at 43° C.; it has a specific gravity of 1.3185 at 17° C., and solidifies at —25° C. into needle-shaped crystals. It is soluble in alcohol, petroleum and chloroform; and it is not acted upon by dilute acids or alkalies. It can be readily distilled without decomposition, but on heating the vapor to 150° C., it is completely dissociated into its components, pure carbon-monoxide being obtained, while the nickel is deposited in a dense metallic film upon the sides of the vessel in which the compound is heated.

After the production of nickel carbonyl had become easy, Drs. Mond, Langer and Quincke directed their attention to the action of carbon-monoxide on other metals. A series of experiments was made with a view to obtain a similar compound with cobalt, which in its chemical and physical behavior so much resembles nickel. The experiments gave, however, the unexpected result that, unlike nickel, cobalt will not combine with carbon-monoxide. Experiments were then made with iron and indications were soon obtained of the existence of a volatile compound of iron and carbon-monoxide; a long time elapsed before this new compound was obtained in a pure state. It was finally isolated in a way similar to that by which the nickel carbonyl had been prepared, and proved to be a somewhat viscous liquid of pale yellow color[4]. Its specific gravity at 18° C. is 1.4664; and it distils completely without decomposition at 102.8° C. under a pressure of 730 millimetres of mercury. When cooled to —21° C. it solidifies into a mass of yellowish needle-shaped crystals. Its chemical composition is somewhat different from the nickel carbonyl, as it contains five equivalents of carbon monoxide to one of iron. The liquid compound, to which the name of iron penta-carbonyl was given, undergoes no change when protected from the action of light, but exposure to daylight for several hours in a sealed tube is attended with the formation of gold colored tabular crystals, and carbon-monoxide is evolved, so that the pressure in the tube rises con-

*This paper on the Mond Process by Sir. W. C. Roberts-Austen, D.C.L., F.R.S. was read before the Institution of Civil Engineers, London, England, on 8th Nov. 1898.

siderably. The crystals have, when dried, a metallic lustre, and resemble flakes of gold; they contain two equivalents of iron to seven equivalents of carbon-monoxide. None of the other metals which were submitted to investigation showed indications of combining directly with carbon-monoxide.

The discovery that in a mixture of metals only nickel and iron would form volatile compounds with carbon-monoxide, and that they could, therefore, be separated from the other metals, was sufficiently important to induce Dr. Mond to arrange laboratory experiments with ores containing nickel, cobalt, iron, copper, etc., such as "kupfer-nickel" and "pyrrhotite." The experiments afforded such promising results, that apparatus of considerable size, though still well within the limits of the resources of a laboratory, was set up, and in it several pounds of ore could be treated with carbon-monoxide.[5] A patent was also applied for on the 12th August, 1890, which describes the way in which such ores may be treated. It is pointed out that the principal nickel ores which are metallurgically treated contain the nickel in combination with arsenic and sulphur besides other metals and gangue. These ores have first to be submitted to the process of calcination, in order that the nickel may be present in the form of oxide, and to drive off, as far as is practicable, the arsenic, sulphur, and other volatile bodies. The resulting oxide of nickel is treated with reducing gases, such as water-gas or producer-gas, in order to convert the oxide of nickel into finely divided metallic nickel; the material containing it then is cooled to about 50° C., and is treated with carbon-monoxide. In dealing with nickel ores which contain

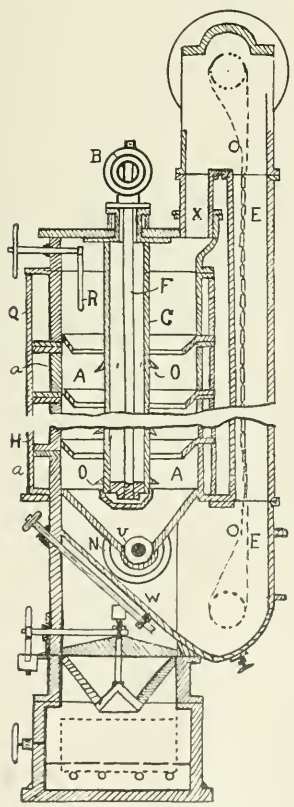

FIG. 1

nickel oxide in chemical combination with silicic acid, arsenic acid, or other substances which cannot be removed by calcination, the ores are so treated as to convert the nickel into nickel speise or nickel matte, which is then subjected to calcination.

In 1892 an experimental plant on a large scale was erected at Smethwick, near Birmingham. After some years of patient work, during which the plant had several times to be reconstructed, in order to meet all the conditions of this somewhat delicate process, the plant gradually assumed the shape shown in Figs. 1. Before describing it in detail it will be well to give a brief account of the operations involved in the process, which are the outcome of many years of practical experience.

The process is more especially suitable for the extraction of nickel from ores which contain copper in addition to nickel and iron. These ores, which have on an average between 2 per cent. and 6 per cent. of nickel and about the same amount of copper, are first subjected to "heap roasting," to eliminate the greater part of the sulphur, and to convert the iron which forms their chief constituent into oxide. The roasting is necessary to enable the iron in the following operation of smelting to combine with the silica present in the ore to form a slag, and thus to effect the separation of the iron from the nickel and copper which unite with the remainder of the sulphur to form a regulus or matte. This matte contains the nickel and copper in a more concentrated form, the amount of each metal being usually 15 per cent. to 20 per cent., the residue consisting mainly of sulphur and iron. To concentrate the nickel and copper still further, the matte is "bessemerized." A sample of such "bessemerized" matte is exhibited; it contains 31.37 per cent. of nickel, 48.62 per cent. of copper and 0.70 per cent. of iron. It was prepared by the Canadian Copper Company, Sudbury, Ontario, from their ores, which contain an average of 4 per cent. of nickel and 4 per cent. of copper. This "bessemerized" matte is crushed, ground, and subjected to a calcining operation so as to convert the sulphides into oxides, and it is then passed through a mill and dresser. This calcined bessemer matte then consists practically of nickel oxide and copper oxide in varying quantities. It has been found in the practical working of the process to be advantageous to further concentrate the nickel by extracting part of the copper at this stage by treating the mixtures of oxides with dilute sulphuric acid, which dissolves about two-fifths of the copper present without taking up more than 1 per cent. to 2 per cent. of the nickel. The copper thus dissolved is in the form of copper sulphate and is obtained in a marketable form by crystallization. The undissolved residue from this operation contains between 45 per cent. and 60 per cent. of nickel, and after drying it is subjected to a carefully regulated reducing process by means of water-gas, after which it is treated with carbon-monoxide to extract part of the nickel present. In this first treatment with carbon-monoxide about two-thirds of the nickel can be easily extracted; after this amount is volatilized the extraction becomes much slower, so that it has been found advantageous to recalcine the residues and repeat the copper extraction, the reduction, and the nickel extraction.

The five operations involved are diagrammatically illustrated in Fig. 2. The process begins, as will be seen, at one end with the material to be treated, "bessemerized" matte; it ends with the market product nickel. The "bessemerized" matte proceeds, as the arrow indicates, to the first operation (1) of dead roasting, and for this purpose any suitable furnace may be employed. After roasting, the matte contains 35 per cent. of nickel, 42 per cent. of copper, and about 2 per cent. of iron.[6] It then passes to the second operation (2) for the extraction of part of the copper (about two-thirds) by sulphuric acid, the copper being sold as crystallized sulphate of copper. The residue from this process contains about 51 per cent. of nickel and 21 per cent. of copper, and passes to the third operation (3) for reducing the nickel and incidentally the remaining copper, to the metallic state, care being taken to avoid reducing the iron. This is effected in a tower provided with shelves, over which mechanical rabbles pass, the reducing agent being the hydrogen contained in water-gas. The temperature does not exceed 300° C., and should be kept lower when much iron is present. From this tower the ore is conveyed continuously to the fourth operation (4) of volatilization, in which part of the nickel is taken away by carbon monoxide and forms the compound nickel carbonyl. The formation of this volatile compound is effected in a tower similar to the reducing tower, but the temperature is much lower, and does not exceed 100° C. From the volatilizer, the ore is returned to the reducer (3), and it continues to circulate between stages (3) and (4) for a period varying between 7 days and 15 days, until about 60 per cent. of the nickel has been removed as nickel carbonyl. The residue from this operation, amounting to about one-third of the original calcined matte, and not differing much from it in composition is returned to the first operation and then naturally follows the same course

[5] Ludwig Mond on "Metallic Carbonyls," Proceedings of the Royal Institution, vol. xiii., p. 668.

as before. The nickel carbonyl, produced in the fourth operation, passes to the decomposer (5). This appliance is either a tower or a horizontal retort, which is heated to a temperature of 180° C., so as to decompose the nickel carbonyl and release the nickel in the metallic form, either on thin sheets of iron or, preferably,

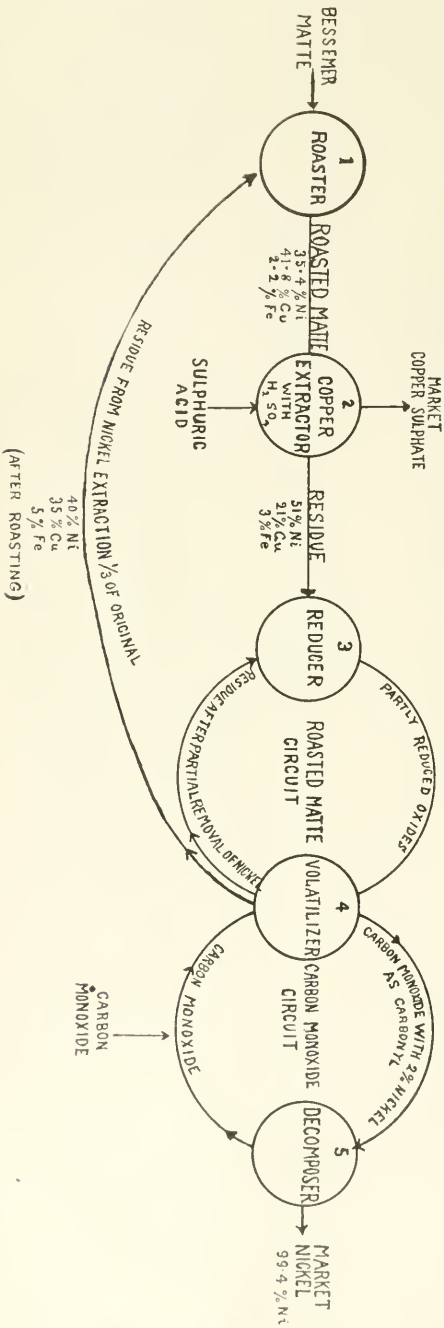

FIG. 2.

granules of ordinary commercial nickel. Carbon monoxide is also released, and is returned to the volatilizer to take up a fresh charge of nickel. It will be evident that, when the operation is in progress, the gaseous carbon monoxide and the partially reduced oxides of nickel and copper are continuously

Average results are given in the Figure, rather than the best which have been obtained.

revolving in two separate circuits which join and cross each other in the volatilizer (4). The commercial product contains between 99.4 per cent. and 99.8 per cent. of nickel.

It will now be possible to proceed to a description of the working as the author saw it in full operation in Smethwick a few months ago. The material under treatment during the author's visit was of Canadian origin, and had been received as calcined bessemer matte containing 35.4 per cent. of nickel, 41.8 per cent. of copper, and about 2 per cent. of iron. This material was first passed through a ball mill and dresser with a sixty-mesh riddle, and was then treated in quantities of 3 cwt. in a small lead-lined mixer with 200 lb. of ordinary sulphuric acid, which had previously been diluted with about 20 cubic feet of mother liquor from previous operations. These appliances are shown in the right hand portion of the plan and elevation, Fig. 1. The temperature of the mixture soon rises by the action between the copper oxide and the sulphuric acid, and is kept, by means of a steam-jet, at a temperature of about 85° C. for ½ hour. From this mixer, the charge is run out into a centrifugal hydro-extractor, provided with a filtering cloth, in which the solution of copper sulphate is separated from the solid residue containing the nickel. After the filtration of the charge is finished, the speed of the hydro-extractor is increased, and the residue is thus rendered sufficiently free from the liquor.

The solution containing the extracted copper runs from the hydro-extractor into a well, from which it is pumped into the crystallizing vats shown in the Figs. After a period of about eight days to ten days, the crystals of copper sulphate are taken out of the vats and the mother liquor is mixed with fresh acid and is again used for the extraction of copper. As already mentioned, a small amount of nickel and a little iron are also dissolved in the sulphuric acid during the copper extraction, so that the mother liquor from which the copper sulphate has crystallized becomes gradually contaminated with these two metals. It is therefore necessary to replace some of the mother liquor from time to time by fresh water, and to recover the nickel from the solution. The simplest method is to evaporate the solution to dryness and to roast the nickel and copper sulphates so obtained. The oxidized material is again introduced into the main process. The copper sulphate crystals from the crystallizing vats are charged into a second hydro-extractor, where they are washed with a little clean water to remove all acidity; they are then dried and are ready for packing. The copper sulphate thus obtained is sufficiently pure for the market, as it contains only 0.05 per cent. of nickel and 0.048 per cent. of iron.

The residue from the copper extraction is taken from the hydro-extractor and stored in a bin until a sufficient quantity has been collected to make up a charge of five to six tons for the nickel-extracting plant. It now contains 52.5 per cent. of nickel, 20.6 per cent. of copper, and 2.6 per cent. of iron. The material is charged by hand at the rate of ½ ton per hour into a feeding-hopper described as the matte inlet in the lower part of the plan, figs. 1, plate 1, which communicates, through a rotary valve, with the conveyor, consisting of a tube enclosing a revolving spiral, which transports the material to an elevator. This lifts the material to the top of the reducing tower, and discharges it through another rotary-valve into this reducing tower.

The reducer and the volatilizer (shown in the centre of Figs. 1), in which the treatment with carbon-monoxide takes place are fully described in Dr. Mond's patent (No. 23,605 of December 10th, 1895). The reducer consists of a vertical tower about 25 feet high, containing a series of shelves, which are hollow so as to admit of their being raised to a temperature of 250° C. by producer gas. The roasted matte falling on these shelves from above is stirred and made to descend from one shelf to that below it by rabbles actuated by a central vertical shaft. Water-gas passes up the tower to effect the reduction of the material. There are about fourteen of these shelves or trays in the tower. The five lower shelves are not heated by producer gas, but are cooled by a stream of water in order to reduce the temperature of the roasted and reduced matte to the temperature at which the volatilizer is worked.

The volatilizing tower resembles the reducer, but the shelves are not hollow, as there is no necessity to heat them. The reduced nickel requires a temperature of only 50° C. to enable it to combine with carbon monoxide and form a volatile compound, and the matte and gas are sufficiently hot to main-

tain this temperature. In the plant at Smethwick the volatilizer was made the same size as the reducer, but in the new plant it is somewhat smaller.

The decomposer has been devised with much care, and has, in its present form, only recently been patented. The nickel is deposited in it, from its gaseous compound with carbon monoxide, on granules of ordinary commercial metal. The arrangements by which this is effected are very ingenious, and may be described almost in the words of Dr. Mond's latest patent. The object is to obtain metallic nickel from nickel carbonyl in the form of pellets, which are specially suitable for the production of nickel alloys. For this purpose gases containing nickel carbonyl are passed through granulated nickel, which is kept at the temperature required for the decomposition of the carbonyl —about 200° C. The nickel which thus separates from the carbonyl becomes deposited on the granulated nickel, which consequently increases in size. In order to prevent cohesion of the granulated nickel, it is kept in motion. When a number of the pellets have attained a convenient size, they are separated by sifting without interrupting the depositing operation, the smaller granules being returned to receive a further deposit from the nickel carbonyl. A convenient form of apparatus for effecting the process described is shown in Figures 3, which represent vertical sections of the apparatus on planes at right angles to each other. A is a cylindrical vessel, preferably built up of short cylinders, *a a*, bolted together; it contains a central tube, C, provided with gas outlet holes, O, through which the gas containing nickel carbonyl, entering at the gas inlet, B, passes into the vessel which is filled with shot, or small granules, of nickel. The gas permeates through the interstices between these granules, and is brought into intimate contact with them, and when the nickel carbonyl is decomposed the nickel is deposited on the granules. The gases finally escape through the outlets, L, into the gas-exit pipe, M. In order to prevent the granules from cohering, they are kept slowly moving by continuously withdrawing some of the granules from the bottom of the cylindrical vessel, A, by means of a right and left-handed worm conveyor, U, which delivers the granules into two sifting-drums, N. The smaller granules fall on to the inclined plane, W, and collect at the base of the elevator, E, which conveys them again to the top of the cylinder, A, and feeds them through the feeding hole, X. In order to avoid the deposition of nickel from the nickel carbonyl in the central tube, C, it is kept cool by causing water to circulate down the tube, F, and up through passages F^1, formed in the central tube, to the water outlet, F^2. The cylindrical vessel, A, is surrounded by a wrought-iron casing, Q, which forms heating spaces, H, communicating with heating-flues, P, which are so arranged that the temperature of each cylinder can be separately regulated by dampers, so as to maintain the temperature of the granules of nickel contained in the vessel, A, at about 200° C., at which temperature the nickel carbonyl is decomposed. With a view to ascertain whether the cylinder, A, is full of granules, a rod, R, is fixed to the spindle of an external handle, which can be turned partly round, so that if the operator feels resistance to the motion of the R, it is certain that the granules extend to that height. The appliance used for depositing the nickel originally consisted of a series of retorts lined with thin steel sheets, on which the nickel was deposited in layers. It was found, however, that the metal so obtained was very difficult to cut, and the apparatus above described was accordingly devised.

A magnified section of a granule of nickel shows that there is a core of nickel which under higher magnification shows a crystalline and convoluted structure, and this core is surrounded by concentric layers. The central core is ordinary commercial nickel, and the layers are nickel deposited from its carbonyl. In some cases granules of deposited nickel are found without any central core. These have grown from minute fragments of deposited nickel which have become detached during the course of deposition.

The water-gas used in the reducer is generated in gas-producers. Anthracite is used to decompose the steam, and the water-gas is collected in a gas-holder, whence it is taken to the reducing tower, to which reference has just been made. This gas contains, on entering the reducer, about 60 per cent. of hydrogen. The reducing operation is so regulated that only a small quantity of hydrogen remains in the escaping gas, as a rule not more than 5 per cent. to 10 per cent. This waste gas is subjected to the action of a fine water-spray, which condenses the steam generated by the combustion of the hydrogen in the water-gas. Part of this waste gas is used for making the carbon-monoxide required in the volatilizer, by passing it through the C O retort charged with incandescent charcoal, which reduces the carbon-dioxide contained in the waste gas, and thus increases the amount of carbon-mononoxide in it. The gas issuing from this retort contains about 80 per cent. of carbon-monoxide, and is stored in another gasholder, which communicates with the main circuit of carbon-monoxide gas. The main circuit of the carbon-monoxide passes through the volatilizer already referred to, where the nickel is taken up. The carbon-monoxide, now charged with nickel, passes through a filter to separate the fine particles of matte-dust from the gases, then through an apparatus called the decomposer, and so described in the Figure. In this decomposer the nickel taken up in the volatilizer is deposited. The gas now deprived of its nickel passes to the C O blower, Figure 1, which sends the carbon-monoxide to the volatilizer in order that it may take up a fresh charge of nickel.

The solid material from which the nickel is being extracted is kept circulating through the reducer and volatilizer for a period varying between seven days and 15 days, during which time the oxides are gradually reduced to the metallic state and the nickel volatilized. When the material originally charged in has had the bulk of its nickel extracted it is run out through a rotary calciner roaster, Fig. 1, which converts the metals into oxides, so that they may be treated for the second time with sulphuric acid and carbon-monoxide. The ratio between the nickel and copper in the residues from the nickel extraction is practically the same as in the calcined Bessemer matte, with which the operations were started, but the amount of iron has increased by the removal of the copper and nickel, as the following figures show: Original matte contains, nickel, 35.27 per cent.; copper, 41.87 per cent.; iron, 2.13 per cent. After the first treatment of copper and nickel extraction, the quantities are, nickel, 35.48 per cent.; copper, 38.63 per cent.; iron, 4.58 per cent., and after the second copper and nickel extraction, nickel, 35.83 per cent.; copper, 35.56 per cent., and iron, 7.82 per cent. The amount of nickel extracted in these two cases was, after the first treatment 61 per cent., and after the second treatment 80 per cent. of the nickel present in the original matte. It must be remembered, however, that in the second treatment only one-third of the original amount remains to be treated, while the final residue is only one-tenth. To avoid the formation of iron carbonyl, the temperature in the reducer has to be kept very low, and if this is done the nickel extracted from a matte originally containing as much as between six per cent. and ten per cent. of iron will not contain more than 0.5 per cent. of iron. If the amount of iron in the residues rises above this percentage, the extraction of the nickel is very much delayed, on account of the low temperature which must be maintained in the reducer. It is necessary, in such a case, to re-smelt the residues before proceeding with the extraction of the nickel and copper. The following are analyses of the deposited nickel:

	I.	II.
	Per cent.	Per cent.
Nickel	99.82	99.43
Iron and (Al O)	0.10	0.43
Sulphur	0.0068	0.0099
Carbon	0.07	0.087
Insoluble residue	....	0.026

The experimental plant at Smethwick has been working for some time, and about 80 tons of nickel have already been extracted in it from different kinds of matte. The results obtained were quite satisfactory, and they point to the conclusion that the process is fully able to compete with any other process at present in use for the production of metallic nickel.

PARSONS' STEAM TURBINE DIRECT-CONNECTED.*

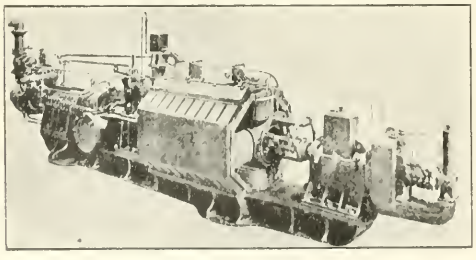
With the steam turbine the conditions are favorable to the larger machines for obtaining the best results and the increase in the sizes manufactured has been rapid, the average at present being about 300 h.p., and we understand that turbo-plants of 4,000 k.w. output are being designed under the Parsons patents for the generation of electrical energy from steam at a very low

*Reprinted from Engineering, London, England.

cost to compete with water power. In the turbine engine, as in the compound triple or quadruple reciprocating engine with which we are more familiar, it is essential for the most economical results, that the capacities of the cylinders should be proportioned to the various stages of the expansion of the steam between the boiler and the condenser. In the ordinary triple-expansion engine this is very incompletely obtained. In the mercantile marine, the ratio of expansion seldom exceeds 16-fold, and in war vessels 9-fold. In the compound turbine any ratio of expansion can be obtained without a material increase in weight or bulk, and in the larger condensing turbine motors, being constructed for driving dynamos, or for marine propulsion, the ratio of effective expansion within the engine is between 100 and 200-fold. It is to this exceptional ratio of expansion, and the economy of the engines themselves, that the satisfactory results which have been obtained in the larger engines are attributed. In the steam turbine the advantages of working expansively are obtained by increasing the length of the blades and diameter of the turbines; and therefore, of course, increasing the area acted on by the steam. In this way, what corresponds in some degree to compounding in a reciprocating engine is obtained, though of course there is not the need to divide the expansion up into stages, as in a reciprocating engine, the expansion being continuous and gradual. So long as the initial pressure is kept constant, the temperature of any one ring of blades will not vary.

The plants, when completed in the machine and erecting shops, are transferred to the testing shop, where they are put under steam, and undergo the usual tests of full and emergency load; the steam consumption being accurately measured. At present the boiler and condenser capacity of the shop is sufficient for prolonged tests up to 500-k.w. output, but this will shortly be increased to 2,000 k.w., when plants up to this size will undergo a full series of tests before being sent out from the works. New large machine-shops, erecting-shops, pattern-shop and offices are at present in course of erection, and will be specially equipped for the production of the larger turbine plants of standard sizes and design for continuous current and single, two, or three-phase alternating current.

We do not propose in these articles entering into the construction of various types of generators made by Messrs. Parsons, as that would take us too far afield, but any description of the works would hardly be complete without some notice of the product. There are thirteen 350 k.w. turbo-alternators now in use for lighting London at the Metropolitan Company's stations at Manchester square and Sardinia street. In the illustration we show a 75-k.w. turbo-generator of another type, four of which have been installed at the Hotel Cecil, London.



Steam Turbine.

The central station of the Newcastle and District Electric Company at Forth Banks, is one of the most important installations undertaken by the Heaton works. A 500 k.w. turbo-alternator has been more recently erected in the same station.

This company obtained powers to supply energy in 1889, and on January 10, 1890, the works were opened with three Parsons turbo-electro generators of 75 k.w. capacity each. The company has been a success in every respect from the first, paying a dividend which has increased every year from 2 per cent. in the first to 8½ per cent. in the last year of working.

The small cost per unit for repairs and renewals—and this figure includes all plant, cables, buildings, etc.—is worth noting; as also is the moderate figure which represents the amount required per unit sold to pay interest on capital at 5 per cent. This is important in view of the results obtained. The works are near the River Tyne, from which water is drawn for condensing purposes. The water pipes are laid in a brick lined tunnel about 100 yards long, and terminate in a condenser chamber sunk to mean tide level. There are two sets of plant, one for surface condensation, dealing with light loads, the other for jet condensation, and capable of condensing 48,000 lbs. of steam per hour. The works are peculiarly formed, being placed on the side of a hill, and the various rooms are as it were terraced out. The place originally formed part of Messrs. R. and W. Hawthorn, Leslie and Co.'s marine engine works, and at present is bounded on one side by that company's locomotive shops. As is well known, Messrs. Hawthorn's marine engine department was, some time back, transferred to St. Peter's, lower down the Tyne, and the electric light company thus were able to find a site well suited for its purpose. Advantage could hardly have been taken of the position, however, had it not been that the Parsons steam turbo-generator occupies so small an amount of space, and also on account of the absence of vibration, no foundation being required for the machinery. With regard to the latter feature, it is of interest to point out that Messrs. Hawthorn's drawing office wall forms a continuation of the engine room retaining wall of the electric lighting station; a fact which, in itself, would prohibit the use of ordinary reciprocating engines. The total area of the engine room is only 400 square yards, and in that space there are at present fixed turbo-generators representing nearly 1,720 k.w., with provision for a total of 3,200 k.w.

The use of the steam turbine for actuating electric generators has hitherto created the chief demand for this motor, but there are some other applications of the steam turbine; amongst these that to fan and pump machinery is of considerable importance. It has been found that a centrifugal pump when somewhat modified, is equally efficient whether it is run at 1,200 revolutions, as it generally is, or at 3,200 revolutions. An ordinary 6-inch pump at 1,200 revolutions will give a lift of about 40 feet, but we learn experiment has shown that the modified pump running at 3,200 revolutions will give a lift of about 200 feet, with proportionately greater output. This equals a discharge of about 1,000 gallons per minute, and gives about 60 water h.p. When this is combined with a 100 h.p. turbine, a very compact arrangement is obtained, suitable for mining purposes. A plant was recently erected at Messrs. Storey Brothers', Lancaster, for 850 gallons per minute, at 160-ft. lift, when run at about 3,200 revolutions per minute, and is reported to have given exceedingly good results. For low lifts, the centrifugal turbine pump is not so suitable, and propeller pumps with screws, somewhat like those of a ship's propeller, are adopted. These are suitable for lifts of from 10 to 40 feet.

Another department of these works is devoted to the manufacture of fans for ventilating purposes, and also for induced and forced draught. For the last three years, a fan 3 feet in diameter has been running at Mr. Cookson's works, Howdon-on-Tyne, drawing hot gases, and exerting a pressure of 7-inch water gauge with 2,000 revolutions per minute. It has practically run day and night since the start. Fans have also been made at the Heaton works for forced draught on board ship, and for land purposes. At the time of our visit one was being erected to give induced draught at 3-inch water gauge to two marine boilers capable of evaporating 25,000 lbs. per hour.

Another application of the fans is for colliery ventilation. Engineering describes a 5-foot fan which has now been running for nearly three years at the Clara Pit, Wylam-on-Tyne, a large colliery in the Tyne district exhausting 120,000 cubic feet per minute at 2¼-inch water gauge; and another fan has just been erected at the Tredegar Coal Company's pit in South Wales for 300,000 cubic feet of air per minute at 3 inch water gauge.

Both fans and pumps are reported to have given good results for economy. One advantage is that practically no foundations are required; in one case the total cost of fan, brickwork and foundations amounted to one-third that needed for an ordinary slow-speed fan. This was largely on account of the small quantity of brickwork and foundations which were necessary. Although we are not entering into many details of construction reference may with advantage be made to the interesting feature of the governing of turbines. It may be effected by an electrical governor, or by a centrifugal governor, as may be found most suitable for the special work. If constant speed is required, as in alternators which have to run in parallel with

others, the centrifugal governor type is adopted; if, however, constant voltage is desired, the electrical governor is used. In the latter the voltage is automatically controlled by the governor, and so accurately can this be done that any desired voltage can be obtained at either full load or no load to within 1 per cent. without altering the governor. Thus, if 5 per cent. rise of voltage is desired at full load in a 100-volt machine, the governor can be adjusted to give 100 volts at no load, and 105 volts at full load. The governor is exceedingly prompt in its action, and large variations of load cause little variation of voltage, thus making the turbine specially suitable for traction purposes.

In both types of governor, one end of a lever is moved up and down either by the centrifugal governor or by a core controlled by a spring, and actuated by a solenoid in shunt with the terminals of the machine. This lever actuates a small valve, which is further moved to a small degree up and down at equal intervals. This small valve, by a steam relay arrangement, actuates the piston, which, in turn, actuates the main admission valve. The result is that at small loads the steam is admitted in a series of equal puffs, thus getting the advantage of the high-pressure steam, and securing great economy at small loads. As the load increases these puffs get longer and longer, until at full load the admission of steam is continuous. The puffs are at such rapid intervals that there is no perceptible variation of the speed of the turbine between each puff. Another advantage of the movement of the valve up and down is that everything is kept in a state of movement, and therefore there is no liability to stick, and all hunting is avoided.

SAND FILTRATION OF PUBLIC WATER SUPPLIES.*

BY R. S. LEA, ASSOC. M. CAN. SOC. C. E.

(Continued from last issue).

The operations which have been described in the foregoing pages are those connected with the carrying on of what is known as continuous sand filtration; and in determining what methods produce the best results, our only test has been the degree of bacterial purification effected. The reason of this is, as we have already seen, that in waters at all likely to be used as public supplies, the actual amount of organic matter is relatively so small as to be of little sanitary significance. Nevertheless, there is a certain degree of chemical purification effected by this process. Analyses of the effluents show a reduction of the dissolved organic matter of from 30 to 60 per cent. This is brought about by the action of the bacteria, which, though existing under adverse conditions, are yet capable of producing this result in the presence of the free oxygen in the water, the amount of which is usually quite sufficient for the purpose. Now, in the case of sewage, which is only very highly polluted water, the amount of free oxygen is very small in comparison with the organic matter present. And it was found, in making experiments on the purification of sewage by passing it through beds of sand, that if air were artificially introduced a very complete reduction of the organic matter would be effected by the bacteria. This was accomplished by working the bed intermittently; that is to say, at regular intervals of time—say 24 hours—the bed was allowed to drain, and fill its pores with the air drawn in after the sewage. After taking this breath the bed rested for a day; then the sewage was again turned on to the surface, preventing the escape of the air which was necessary to provide oxygen for the next 24 hours' purification. The same method used in connection with water is what is termed intermittent filtration. The first filter of the kind was built at Lawrence, Mass., by H. F. Mills, C.E., member of the State Board of Health. Since then, small plants on the same principle have been built at Mt. Vernon, N.Y., and Grand Falls, North Dakota. The results do not seem to indicate any necessity for their use, not being at all superior to those of continuous filters, while the method of operation is not suited to cold climates, and either requires a greater area of bed or a higher rate of filtration. A description of the Lawrence filter may be found in Trans. Am. Soc. C.E., 1893, p. 350.

From what has been said, it will be evident that where the water is at any time liable to turbidity, a settling basin, capable of holding from 12 to 24 hours' supply at least, must be provided. Also, in order that the filter may be able to work continuously at a uniform rate, a clear water basin will be necessary of a capacity sufficient to cover the maximum fluctuations in the consumption. If the supply is from a storage reservoir, the filters are placed below the dam, and are, of course, supplied by gravity. But even when the supply is from a river or lake, the topography of the ground often admits of the same economical arrangement. If this is not possible, the water must be pumped into the settling basin by a separate pump of the low lift variety. The extra expense of two pumpings may be almost eliminated if the same station, boiler plant, etc., can be made to serve for both pumps. The total area of filter beds required depends in the first place upon the maximum rate adopted; and, second, upon the area out of use while being scraped and refilled. The higher the rate of filtration the less the total area, and therefore the first cost of the plant. The principal item of expense connected with the operation of this plant is that for scraping; and it is found that the amount scraped for any given quantity of water filtered is independent of the rate. Also, the allowance for the area out of use will not vary with the rate to any extent. Hence an increase in the rate will not by any means produce a proportionate reduction in the cost of filtration. A rate of 3,000,000 gallons per acre of bed in use will give results entirely satisfactory from the standpoint of efficiency, and at a cost which is usually by no means excessive.

The size of the individual beds will depend in part upon the extent of the total area, the smaller plants having necessarily to use smaller beds. A large bed costs less per unit of area than a small one, on account of the proportionately greater length of wall in the latter case. With a large bed it is, however, probably more difficult to obtain a uniform rate of filtration over the whole area. During the winter of cold climates the cost of maintenance is considerably increased by the expense of removing the ice which forms in the bed. It is also difficult to avoid injuriously disturbing the surface of the sand. Beside this, when the water is drawn down the surface sometimes freezes before it can be scraped. On account of such disadvantages as these filter beds should be covered in all cold climates. The best method of constructing these roofs has already been referred to. The proper number, shape, and area of the beds of a system can only be determined for any particular case by careful study of the local conditions, and by making comparative estimates of the different items of cost of construction, maintenance, etc. There will be opportunities for the exercise of considerable ingenuity in the general laying out of the system, the relative placing of its parts, the arrangement of the piping, drains, etc., in order that convenience and economy may be happily combined.

The cost of construction will of course depend on the local circumstances and the kind of materials used. As in all hydraulic work, great care is required in the construction, and the best quality of materials must be used. In the main, it is the same class of work as is required in the building of distributing reservoirs. The following table gives the cost of construction for several European and American filters:

Place.	Cost per Acre.	
	Covered.	Open.
London		$24,000—$40,000
Berlin (1884-87)	$66,000—$70,000	
Hamburg (1893)		30,500
Warsaw (1885)	78,000	
Zurich (1885)	86,000	
Nantucket, Mass. (1892)		45,500
Hudson, N.Y. (1874-88)		73,000
Ilion (1893)		96,700
Ashland, Wis., (1897)	80,000	
Somersworth, N.H. (1898)	64,000	
Poughkeepsie, N.Y. (1872)		90,000
Poughkeepsie, N.Y. (1896)		41,000

Lindley gives the general cost of continental filters as $45,000 per acre for open, and $68,000 for covered. The following figures, giving in detail the bids received February 15th, 1898, for constructing the water filtration plant now in process of construction at Albany, N.Y., will be of more interest. When completed it will be by far the largest plant yet built in America; and in general design and completeness of equipment it will be second to none. It will consist of a settling basin of 16,000,000 gallons capacity, eight covered filter beds, each with 7-10 of an

*From a paper read before the Canadian Society of Civil Engineers.

acre of sand surface, and a clear water reservoir with a capacity of 100,000 gallons. There will also be provided an office building containing fully equipped chemical and bacteriological laboratories. The price for the sand and gravel included the necessary screening, washing and putting in place. The sand washer is of the ejector type. The bids are as follows:

Material.	Quantities.	Prices of Successful Bidder.	Other Bidders.	Engineer's estimates.
Shale rock excavation	5,000 cubic yards	$ 1.20	$ 0.30 to $ 1.50	$ 0.80
Earth excavation (above grade)	60,000 cubic yards	.27	.13¼ to .476	.20
Earth excavation (below grade)	3,000 cubic yards	.30	.20 to .60	.40
Rolled clay and gravel embankments	21,000 cubic yards	.52	.45 to .90	.50
Silt and loam filling	23,000 cubic yards	.15	.15 to .50	.20
General filling (rolled)	18,000 cubic yards	.18	.07 to .40	.20
Puddle in place	13,000 cubic yards	.71½	.67 to 1.07	1.00
Broken stone or gravel for lining	1,900 cubic yards	.85	.99 to 1.40	1.25
Sodding	3,000 square yards	.15	.15 to .60	.15
Seeding	8 acres	25.00	12.50 to 70.00	50.00
Gravel in roadway rolled	800 cubic yards	.60	1.00 to 1.50	1.00
Vitrified brick laid as paving	120 M	20.00	18.00 to 30.00	20.00
Stone curbing	800 lineal feet	.60	.75 to 1.50	.50
*Concrete in floors	11,000 cubic yards	2.31	2.34 to 3.50	3.00
*Concrete in vaulting	7,000 cubic yards	3.85	3.90 to 7.50	5.00
Other concrete	3,000 cubic yards	2.13	2.50 to 4.30	3.00
*Brick work	4,500 cubic yards	8.12½	7.00 to 10.00	6.00
Imported Portland cement	500 bbls.	3.12½	2.35 to 3.00	2.75
American Portland cement	14,000 bbls.	2.14½	1.90 to 2.21	2.15
Rosendale cement	1,500 bbls.	.97½	.85 to 1.95	1.00
Furnishing and placing 2-inch drain pipe in piers		525.00	300.00 to 1,318.00	700.00
2-inch agricultural drain pipe	2,000 lineal feet	.04	.05 to .10	.05
*6-inch drain pipe, open joints	16,000 lineal feet	.11	.10 to .12½	.10
Furnishing and laying all vitrified pipe cement joints		5,337.00	3,850.00 to 5,933.00	6,000.00
*Placing all gates, etc., furnished by board		1,140.00	700.00 to 2,000.00	470.00
*Furnishing and placing all cast-iron pipe and specials		20,701.25	14,750.00 to 20,000.00	15,000.00
*Iron filter covers	672 each	4.40	5.00 to 6.50	5.00
*Sand washing apparatus	2 sets	393.00	250.00 to 1,000.00	800.00
*Sand run fixtures	8 each	407.50	100.00 to 511.00	200.00
*Regulator houses	8 each	862.24	175.00 to 900.00	500.00
*Office and laboratory building		4,881.00	2,700.00 to 10,200.00	3,000.00
*Filter gravel in place	7,000 cubic yards	1.05	1.00 to 2.00	1.50
*Filter sand in place	36,000 cubic yards	1.00	.90 to 1.78	1.25
Split stone lining	2,000 square yards	.82	1.03 to 3.60	2.00
Rough stone paving	200 square yards	.82	.93 to 2.50	.80
Fasteners furnished and placed in concrete vaulting	3,000	200.00	150.00 to 225.00	100.00
Iron fence	850 lineal feet	2.00	1.00 to 2.00	1.00
Connection with pump-well and closing old intake		3,000.00	1,000.00 to 4,000.00	3,500.00
Total		$300,866.00	$322,358.00 to $387,345.00	$322,440.00

The items of special interest are marked thus *

It will thus be seen that a covered filter plant of this area (5.6 acres) with settling basin, clear water basin, and all other appurtenances complete can be built for less than $50,000 per acre. For further details and information concerning this plant see Engineering News, Feb. 10th and Oct. 20th, 1898.

The total cost of maintenance of a filtration plant is made up of the operating expenses, and the interest and sinking fund charges. The former—the operating expenses—comprise: (a) The cost of superintendence, and of attendants to look after the regulation, etc.; (b) the cost of scraping and removing the sand; (c) the cost of washing the sand; (d) the cost of replacing the washed sand when renewal of the bed becomes necessary.

It is only in very large plants that a special superintendent is required, so that the expense for that purpose would not form a very large part of the total cost. The proper handling of the gates, and the running of the plant in general requires a degree of intelligence considerably above that of the ordinary laborer. The wages of the gatemen therefore will be from $2 to $3 per day. Scraping and removing the sand by wheelbarrows seems to cost, under ordinary circumstances, between $40 and $50 per acre, depending upon the wages paid. At Mount Vernon, N.Y., the shovellers and barrow wheelers are paid $1.10 per day, and the scrapers $1.25. Chas. Fowler, for many years in charge of the filters in Poughkeepsie, N.Y., says that one man working one hour is required for every 150 square foot of surface cleaned and removed. This would cost at $1.50 per day, about $43.50 per acre. Lindley gives 30 days at 10 hours each for every acre, which at the same rate is $45 per acre. In the small plants at Ilion, N.Y., and Ashland, Wisconsin, the cost is at the rate of about $50 per acre. The cost of sand washing varies with the method employed. In Poughkeepsie, when they used a simple inclined trough and water jet, it cost as high as $1.50 per yard. By improving their methods they reduced this cost, till to-day it is only 27 cents per yard. In Hudson, the cost is 20 cents per yard, and in Ilion 18 cents. In Germany it varies from 14 to 20 cents per yard.

The periodical replacing of the sand in the bed must be done carefully of course, but should not cost, including whatever is necessary to be done to the permanent layer, more than 40 cents per cubic yard. The cost of these various operations will of course depend upon the scale on which they are carried on. It will obviously be easier to keep the price low with a large plant than a small one. In the case of the former a force of gatemen and laborers can be permanently employed. In the smaller plants the operations of scraping and sand washing only take place at intervals, and are performed by laborers hired temporarily for the purpose, or by employees from other parts

of the water system. In using the above data to make an estimate of the total operating expenses, we shall employ as a unit the cost per million gallons of water filtered. Assuming an average yield of 50 million gallons per acre between scrapings, the total cost would be as follows:

Scraping and removing at $45 per acre	$0.90 per mill. gals. filt.
Washing 100 cu. yds. sand at 25c. yd.	0.50 per mill. gals. filt.
Replacing, etc., at 40c. yd.	0.80 per mill. gals. filt.
Superintendence, etc	0.25 per mill. gals. filt.
Total	$2.45 per mill. gals. filt.

To this should be added the cost of bacterial analyses of the effluents which should be made as frequently as possible in order to test the working of the filters. In many of the European plants a fully equipped laboratory is included in the equipment; and some of the superintendents, like Piefke, chief engineer of the Berlin works, are also expert bacteriologists. The actual cost of the operations discussed above for some American filters is as follows:

Poughkeepsie, N.Y., for 20 years aver.	$2.90 per mill. gals. filt.
Hudson, N.Y., is given as	1.38 per mill. gals. filt.
Mount Vernon, N.Y., a little less than	2.00 per mill. gals. filt.
Ashland, Wisconsin, estimated to cost	2.25 per mill. gals. filt.

The following table furnished by W. B. Bryan, Esq., chief engineer, East London Water Co., gives the yearly cost of filtration of the London Water Companies from 1890 to 1895:

COST PER MILLION U.S. GALLONS.

Name of Company.	1890-1	1891-2	1892-3	1893-4	1894-5
Chelsea	$ .72	$ .75	$ .62	$1.16	$ .60
East London	1.42	1.54	1.42	2.63	1.69
Grand Junction	1.33	1.24	1.30	2.00	1.68
Lambeth	.86	1.01	1.20	1.46	2.54
New River	1.02	.93	1.17	1.43	1.03
Southwark and Vauxhall	$1.17	$1.15	$1.26	$1.53	$1.34
West Middlesex	1.01	.97	1.42	.95	.96

To get the total cost of maintenance, we must include with the operating expenses the charges for interest and sinking funds. This will of course depend upon the cost of construction; and the latter will vary with the maximum rate of filtration adopted, and the proportion of the total area to be out of use while being cleaned. These being decided upon, it will then be easy to calculate the first cost per million gallons of daily yield. For example, if, with the rate chosen, the daily yield of the plant will be 2,000,000 gallons per acre of the total area of beds, the first cost per million gallons will be half the cost of construction per acre, and so on. The diagram gives the cost per million gallons filtered, corresponding to different construction costs, which will pay the interest and sinking fund charges necessary to cancel the whole first cost with interest at the end of 40 years. For example, with a first cost of $60,000 per acre, and a net yield of 2,000,000 gallons per acre of total area, the cost per million gallons with interest at 4 per cent. would be $4.15. With interest at 4½ per cent., and a first cost of $80,000 per acre, first cost would amount to about $6. Add to this $2.50, for the expense of operation, and we should have $8.50 as the total cost of filtering 1,000,000 gallons of water, or 1,000 gallons for less than 9-10 of a cent.

Having now discussed the method and cost of sand filtration, the next and last question to be considered is the nature of the results which this process can be depended upon to produce. There can be no question as to its efficiency from an aesthetic point of view. The complete removal of even the most minute particles in suspension, together with a large part of the dissolved organic matter, ensures the entire elimination of any characteristics the water may possess which would be disagreeable to sight, taste or smell. Yet it is because of the effectiveness of the purification from a sanitary standpoint that this system is especially noted. This is due to its destructive effect upon the bacteria, which is almost sufficient to cause their disappearance during the passage of the water through the filter. The average reduction in a well designed and well managed plant will be as great as 98 or 99 per cent., as shown by comparing the number of germs in the effluent with that in the applied water. But in reality it is even greater than this. For it has been shown that of the few bacteria which are present in the effluent, a certain number come from the underdrains, and have therefore not passed through the filter at all. These belong to some of the species of water bacteria, and, consequently, will be quite harmless. From tests made on the experimental filters at Lawrence with an easily recognized and hardy species, the actual reduction was found to be from 99.9 to 100 per cent. Now, when it is considered the filter is capable of producing such effects upon bacteria which exist normally in water, it will be evident that the effect upon the pathogenic or disease germs which are out of their natural habitat and in a decidedly unfavorable environment will be much greater. Thus what may be called the "hygienic efficiency" of this system must be remarkably high. The process is comparable to nature's method of purifying the surface water which furnishes the underground supplies; and if properly carried out, the water produced is probably of almost equal wholesomeness. The continued experience of places where sand filtration plants have been in operation for some time only goes to strengthen this conclusion.

In America the method is only just beginning to be employed. Up to the year 1892 there were but two plants of this description in the country, viz., those at Hudson and Poughkeepsie, which have been already referred to. Since that time 14 new ones have been completed, and three others are under construction, the latter including the large plant at Albany. The experience to be derived from these plants is too limited to be of much value for some time to come; but the officials connected with the majority of them have invariably expressed their entire satisfaction with the method of working and with the results obtained.

(To be continued).

Industrial Notes.

The Calgary Milling Co. will build an elevator.

At Truro, N.S., T. G. McMullen is completing a pulp mill.

Goderich, Ont., has voted a bonus of $10,000 to the Kensington Furniture Co.

Windsor, Ont., is buying a site for a drill shed to be built there by the Dominion Government.

The contract for the new public works office at Regina, Assa., has been let to Willoughby & Mallard.

G. H. Hopkins and J. D. Flavelle have bought the Lindsay, Ont., waterworks. F. K. Begbie will be manager.

The ratepayers of Woodstock, N.B., will vote on a bylaw to give a $50,000 bonus to a pulp mill on October 16th.

Kamloops, B.C., has voted $27,000 to improve the waterworks, and $15,000 to extend the electric light plant.

An addition will be erected to the John H. Stratford Hospital, Brantford. An isolation hospital may also be built.

The overhead bridge across the M.C.R. near Kingsmill, Ont., which was recently burned, is being replaced by a new one.

H. M. Whitney, Boston, president of the Dominion Iron and Steel Co., has given $25,000 to build an hospital in Sydney, Cape Breton.

The Canadian Rubber Co., Montreal, has ordered a 100 h.p. Mumford Improved boiler from the Robb Engineering Co., Amherst, N.S.

Joseph Black, Toronto, has been continued as editor of The Iron Moulders' Journal by the Iron Moulders' Association of North America.

The boiler inspectors in Montreal are enforcing the city bylaws requiring the use of smoke consumers, and heavy fines are being imposed.

The L.E. & D.R.R. is pulling down its grain elevator at Port Stanley, Ont., which was built four years ago, and removing it to Sarnia.

Smith's Falls, Ont., has appropriated $150,000 to put in a system of water supply and sewage. Willis Chipman, C.E., has prepared the plans.

Graham Moon, of the Postoffice Department, Ottawa, is said to have invented a roller boat, which it is claimed is better than Knapp's failure.

The Kingston School of Mines is trying to secure $6,000 to equip a new laboratory. The expenses last year were $2,070 in excess of the receipts

The contractors have commenced work on the Hoepfner Refining Co.'s nickel works at Hamilton.

John Dittrick's bolt and nut factory at Perth, Ont., is nearly completed and will soon be in working order.

The annual convention of the International Building Inspectors' Association took place a month ago in Quebec.

Brantford, Ont., will build a new Isolation Hospital, and make a large addition to the John H. Stratford Hospital.

The scale manufacturers of the United States are, it is said, to form a trust which will combine most of the leading makers.

W. J. Hamilton, Peterborough, Ont., has invented an improvement in gasoline engines, which is attracting some attention.

Robt. Cameron, contractor, Almonte, Ont., has a contract for building a new wing to Rideau Hall, the official residence of the Governor-General, Ottawa.

The Lillie foundry, Perth, Ont., has passed into the hands of a new firm, The James Bros. Foundry Co., which will operate it on a large scale, it is said.

A bylaw granting W. W. Ogilvie, of Montreal, exemption and free site for his flour mill and elevator at Fort William, Ont., was carried Sept. 11th.

J. E. Asquith and others of Ottawa, Ont., propose to put in waterworks and sewage in Arnprior, Ont. They would also take over the electric light plant.

The Mattawan Iron Co. is in correspondence with the town of Fort William over the $50,000 bonus for a smelter, which that town has been offering for some time.

A steam plough has been successfully tested at Morris, Man. It will plough 18 acres per day with ease, according to the testimony of the mechanic who made the test.

The contract for raising the piers of the Edmonton, N.W.T., bridge has been let to the Dominion Bridge Co. It has been decided to add eight feet to the present height.

The acetylene gas apparatus in T. Ivory & Co.'s store, Omemee, Ont., exploded, September 26th. The generator was wrecked, but no considerable damage was done the building or contents.

The William Kennedy & Sons, Ltd., Owen Sound, is building an extension to its foundry. The addition, which will be used for the manufacture of steel castings, will give employment to between twenty-five and thirty men.

The following were elected officers at the convention of the United Brotherhood of Railway Trackmen in Ottawa: President, J. Logan, Ottawa East; vice-president, J. Hogan, Ottawa; secretary, H. McKenny, Ottawa; treasurer, A. Thompson, Ottawa.

St. Henri, Que., council has granted a tax exemption to the Merchants' Cotton Company to erect a factory in the municipality. The following proviso was made: "The company will have to agree to employ three hundred persons, to whom a yearly sum of $50,000 will have to be paid as salary."

The Nova Scotia Steel Company is making preparations for building another smelting furnace. The large steel building will be extended some eighty feet to cover the new furnace, and bring the steel travelling crane in connection with it. The furnace will produce 100 tons of steel a day.

The large iron works of Carrier, Laine & Co., Levis, Que., are crowded with orders. The establishment employs about 425 hands, and all are busy. Within the last three months a general increase in the wages has taken place, and the men are now receiving about fifteen per cent. more than formerly.

McLachlin Bros., Arnprior, lumbermen and sawmill owners, chartered two C.P.R. trains and gave a free trip to the Ottawa Exhibition to their employees, and paid not only the fare of the excursionists, but their entrance fee to the Exhibition. Thirteen hundred men, women and children were thus entertained.

A. S. Chrystal is giving up his business as steam boiler manufacturer here, and will remove to London, to enter the London Engine Supplies Co. The company will manufacture steam boilers and steam heating appliances, will sell engines, boilers, etc., and will conduct a repair shop for engines and other machinery.—Goderich Signal.

The Simcoe Peat Fuel Company, Barrie, Ont., commenced operations a short time ago, and this industry promises to give employment to a large number of men.

Frank White, representing the Canadian Peat Fuel Co., Toronto, has gone to Tullamore, Ireland, where he is going to install a plant for the Canadian Peat Fuel Co.

H. E. Hill, of Halifax, N.S., has ordered a 100 h.p. steam plant from the Robb Engineering Company, Ltd., Amherst, N.S., for the new works of the Maritime Explosives Company.

The Good Roads Machinery Co., of Hamilton, has taken action against the Sawyer-Massey Co., of the same city, to restrain it from using the phrase, "good roads" in connection with its business.

Notice is given of application for the incorporating of the Aroostook Power Company to erect mills and plant for the manufacture of lumber, pulp and paper at Aroostook Falls in Victoria county, New Brunswick.

J. W. Wilson, Ottawa, has bought two marine type 3 h.p. gasoline engines from the McLachlan Electric and Gasoline Motor Co., Toronto. One of these Mr. McLachlan states is for export to the United States, having been bought for a summer visitor by Mr. Wilson.

The W. R. Brock Quarry Co., Toronto, has bought the Mount Johnson Granite Quarry Works from J. M. Hazel & Co., and has also purchased the Stanstead, Que., granite quarries, including the rights and plant of the Morr Granite Co., with three miles of railway track.

As mentioned last month the business of Tingley & Stewart Mnfg. Co., makers of rubber stamps, etc., Toronto, has been bought by Bernard Cairns, whose familiarity with every detail of the business and exact knowledge and careful methods of carrying it on ensure all patrons that their work will be turned out promptly and as ordered.

The Georgian Bay Portland Cement Company, Ltd., is a new industry established this year in Owen Sound, Ont. Buildings are now practically completed, and manufacturing operations commenced. Seventy-five men will be given employment, and the wages will amount to between $2,500 and $3,000 a month. The output will be 400 barrels per day, and it is expected this will be doubled in the next two years.

The British Government, after careful tests of every known material used for boiler covering, has selected mica covering for Her Majesty's new yacht. After looking into the qualities of mica as a pipe and boiler covering a number of English capitalists have formed a strong company to manufacture boiler covering under the patents of the Mica Boiler Covering Co., of Toronto.

R. H. A. Hunter, W. Hunter, A. Malcolm, G. M. Mackendrick, J. L. Murray, D.D., W. C. Loscombe, J. Boyer, DeW. H. Martyn, M.D., J. Ruettel, G. Wood and J. B. Watson, Kincardine, Ont., and J. Warren, C.E., Walkerton, Ont., have been incorporated as the Hunter Bridge and Boiler Company of Kincardine, Ltd.; capital, $25,000; to carry on the business of Hunter Bros., Kincardine, Ont.

P. Lyall & Sons, Montreal, have installed a large diamond saw, electrically driven, in their stone cutting yard. This saw is a part of the $20,000 electric plant recently purchased by the firm, and includes a travelling derrick and two planers, one of the largest capacity yet made, and the second of smaller size. There are but four of the derricks in use in the stone yards of the United States, and no other in Canada.

E. Leonard & Son made a very fine display of their engines, etc., at the Exhibition recently held in St. John, N.B. Among those who have bought their engines recently from this firm are, W. H. Fowler, of the West End, a 250 h.p. engine to be used in his flour mill. J. W. & W. A. Hutchinson, of Berwick, N.S., have bought the large engine exhibited in the booth. The Acadia Electric Co., of Wolfville, N.S., have sent in an order for one of this firm's 120 h.p. peerless self-oiling engines. J. R. Caulder & Son, of Pepperville, N.S., have ordered a 60 h.p. outfit; E. H. Pickett, of Bridgetown, N.S., a 35 h.p. engine; M. Graves, of Annapolis, N.S., a high-speed engine, and Charles H. Brown, who is starting in operation his new flour mill at Gagetown, has ordered a steam outfit.

A. O. Norton, manufacturer of ball bearing jacks at Coaticooke, Que., has just shipped a large order to Denmark. Several other important orders for export to India, Australia and South Africa have just been received.

Hon. George G. King, Chipman, B.C.; Hon. Ambrose D. Richard, Dorchester; Henry C. Read, Sackville; M. Lodge, Moncton; E. Hutchinson, Douglastown; W. Kitchen, Fredericton, and W. Frank Taylor, Hillsboro, are to be the provisional directors of the New Brunswick Petroleum Co., Ltd., for which a charter has now been applied for. The company will bore for oil; its chief place of business is to be Moncton, N.B., and its capital $1,000,000.

The Owen Sound, Ont., Iron Works Company, Ltd., have revived the business of the old Corbett foundry firm, which closed up during the hard times of a few years ago. They commenced operations last January, and give employment to twenty-five men. The company contemplates enlarging its foundry, increasing its staff and going extensively into the manufacture of propeller wheels, according to a recent report in The Toronto Globe.

The following tenders for the construction of the new drainage system for Lachine, Que., were received: Albert Dini, $209,129.74; Rheaume & Dansereau, $144,816.90; Leopold Leger, $163,230; Chartier & Rebin, $174,095; Martineau, Son & Lemoine, $185,000; Bastien, Valiquette & Parker, $152,523.15; O. L. Hainault & Co., $149,552; Amyot, Lemay & Gauthier, $141,518.88. The contract was awarded to Bastien, Valiquette & Parker, whose tender, though not the lowest, was deemed to offer the best guarantees for the satisfactory execution of this important public work.

Harding & Leathorn, London, Ont., have the contract for building the waterworks at St. Mary's, the figures being $10,081. The specifications call for: All labor in laying the cast-iron pipe distribution system, comprising 1,000 feet of 10-inch pipe; 4,000 feet of 8-inch pipe; 10,600 feet of 6-inch, and 8,000 feet of 4-inch; setting 52 fire hydrants; setting 34 valves; furnishing material for and building 17 valve chambers and setting 17 valve boxes. The contractor also furnishes all materials required except the cast-iron pipes, the pipe specials, the fire hydrants and the valves.

The Canadian Hardware Association at its annual convention in Hamilton, Ont., last month, elected these officers for the ensuing year: President, T. H. Newman of Caverhill, Learmont & Co., Montreal; vice-president, Peleg Howland of Howland, Sons & Co., Toronto; secretary-treasurer, R. and T. Jenkins, Toronto; Executive Committee, Thomas Lee of Rice Lewis & Son, Toronto; R. Angers of Frothingham & Workman, Montreal; E. Jeanotte of L. H. Herbert & Co., Montreal; William Vallance of Wood, Vallance & Co., Hamilton, Ont.; John Bowman of Bowman Hardware Co., London, Ont.

For purposes of record and identification, the Detroit Lubricator Co., Detroit, Mich., has numbered its sight feed lubricators consecutively from No. 1 upwards, so that the number appearing on any lubricator shows how many had been manufactured up to its time. On Sept. 15, 1899, there was completed lubricator No. 400,000. When it is considered that as a rule only one lubricator is used on an engine this figure gives eloquent testimony to the very general use of the Detroit lubricators. The present output of sight feed lubricators alone, of this company, amounts to over 5,500 per month. The Detroit Lubricator Co. also reports a rapidly growing trade in its new style glass oilers and oil pumps.

The F. D. Cummer & Son Co., Cleveland, Ohio, the manufacturer of the well-known Cummer Mechanical Dryers, reports the following sales and shipments for the past two months: Laflin & Rand Powder Co., Pleasant Prairie, Wis., one special dryer to dry 1½ tons of nitrate of soda per hour; United States Navy, Indian Head, Md., one special dryer to dry 1 ton of nitrate of soda per hour; Trent Valley Peat Fuel Co., Peterborough, Ont., one No. 00 "Salamander" dryer to evaporate 2½ tons of water per hour from peat fuel; Warren-Burnham Portland Cement Co., Craigsville, Va., one No. 8 style "F." dryer to dry 2½ tons of slack coal per hour; Peerless Portland Cement Co., Union City, Mich., one No. 00 "Salamander" dryer, to evaporate 2 tons of water per hour, from marl; John McGillen, Chicago, one Cummer portable railroad asphalt paving plant, guaranteed to lay 2,000 yards of 2-inch topping per day of ten hours; Societe Anonyme de Ciments de Vise, Brussels, Belgium, one No. 000 size "Salamander" dryer to dry 15 tons of chalk per hour, and one No. 2 size "Salamander" dryer to dry four tons of clay per hour; T. Herbert Wymonds, Vancouver, B.C., one No. 00 style "F" dryer, to dry 50 tons of fish scrap per day; Pennsylvania Salt Mnfg. Co., Natrona, Pa., one 3 tunnel, 6 track tunnel system complete, for drying iron ore briquettes; Vulcanite Portland Cement Co., Phillipsburg, N.J., one No. 0 style "F." dryer for drying 75 tons of slack coal per day; Wm. Krause & Sons Cement Co., Martins Creek, Pa., one No. 8, style "F." dryer for drying 2½ tons of coal per hour; Premier Tripolite Co., North Sydney, N.S., one special dryer for drying tripoli.

Electric Flashes.

The Montague, P.E.I., Electric Light Co., is making preparations for lighting the village.

Nelson, B.C., is installing additional power for its lighting service, and will shortly be able to supply 4,500 16-c.p. lamps.

The village of Weston, Ont., intends to buy the water-power on the River Humber, and run its proposed electric light plant.

It has been stated recently that the street railway, gas and electric light and power companies in Brantford, Ont., were to be combined.

At the annual meeting of the Quebec Electric Railway, Light and Power Company, A. Thomson was elected president in place of H. J. Beemer.

A project for the construction of an electric railway from St. Catharines to Wellandport, Ont., traversing Fonthill and Pelham, is under consideration.

W. W. Brown, in charge of the lighting plant at Petrolia, Ont., since its establishment, has gone to Camp McKinney, B.C., to take charge of the plant of the Minnehaha Mining Co.

The transfer of the Hamilton and Dundas Railway to the Cataract Power Company was completed Sept. 17th. The company paid $110,000 cash besides assuming bonds amounting to $90,000.

Application is to be made for a charter for an electric or steam railway from Ottawa to Brockville, Ont., with power to operate a ferry on the St. Lawrence, between Brockville and Morristown, N.Y.

The Brantford Electric and Operating Co., Brantford, Ont., is rapidly increasing its power business. The Keys Somerville Printing Co. has installed a 3 h.p., two-phase S.K.C. induction motor with which to operate its new printing presses.

E. H. Caughell, Mary L. Caughell, A. E. Marlatt, Emma L. Marlatt and W. T. Williams, St. Thomas, Ont., have been incorporated as the Port Stanley Electric Railway Co., to build an electric railway from St. Thomas to Port Stanley; capital, $40,000.

Liverpool, N.S., has taken up the municipal electric lighting business, and placed an order with the Royal Electric Co. for a 75 k.w. two-phase S.K.C. generator, as well as the full complement of transformers, and other apparatus. The plant is to be in operation by November 1st.

The Royal Electric Co., Montreal, was awarded the contract for installing the new electric light plant to be added to the plant of the corporation of Picton, Ont. The new plant is to consist of one 120 k.w. S.K.C. two-phase generator, with the full complement of transformers, lamps, etc.

An electric railway between Port Stanley, St. Thomas and London, Ont., the track to be laid along the gravel road connecting those places, is now talked of. A company has been incorporated to build the road, which if successful is to be followed, it is said, by an electric road to Aylmer, Ont.

The corporation of the city of Winnipeg through its Water and Light Commissioners has awarded the contract for the incandescent electric lighting plant to the Royal Electric Co., Montreal. The plant is to consist of a 60 k.w., S.K.C. two-phase alternating generator, with the necessary transformers, etc. The order for the arc apparatus was placed with the Western Electric Co., Chicago, Ill.

The capital of the Citizens' Telephone and Electric Co., Ltd., Rat Portage, Ont., is to be increased from $40,000 to $90,000.

The Mineral Springs Furniture Co., of Preston, Ont., has installed a dynamo and electric lighting plant in its factory.

J. H. Jones has completed the plans and specifications for the Sarnia, Ont., Street Railway Company's proposed new electric line.

The St. Hyacinthe Electric Railway Co. is applying for a Quebec charter to build an electric railway in the counties of St. Hyacinthe and Bagot.

The Hamilton Electric Light and Cataract Power Co. has had certain changes made in its charter enabling it to take over the management of companies of whose stock it has acquired at least two-thirds.

The Robb Engineering Co., Amherst, N.S., is supplying the town of Neepawa, Manitoba, with the steam plant for its new electric lighting system; a 100 h.p. compound engine and two 75 h.p. Mumford improved boilers.

The Royal Electric Co., Montreal, announced a cut of 30 per cent. in electric light rates on Sept. 15th, and the Lachine Rapids Land and Hydraulic Co. has followed with a reduction of 40 per cent., taking effect October 1st.

W. H. Pearson, W. H. Pearson, jr., W. E. H. Massey, J. W. Flavelle, Toronto, and R. Weddell, Trenton, Ont., have been incorporated as the Trenton Electric and Water Co., Ltd.; capital, $400,000; head office, Toronto.

The Ottawa Electric Railway Company has let a contract to Heney & Smith, of Ottawa, for the construction of an electric radial line from Ottawa to Britannia, on Lake Dechene, seven miles. The road is to be completed by November 1st.

J. Playfair, Geo. Chew, D. L. White, jr., and P. Potvin, Midland, Ont., W. J. Sheppard, W. H. F. Russell, W. J. Lover ing, of the township of Tay, county of Simcoe, Ont.; J. J. Drummond, Radnor Forges, Que., have been incorporated as the Midland Power Co.; capital, $90,000; to supply heat, light and power.

At a meeting of the shareholders of the Royal Electric Company, R. Forget, president, in the chair, the bylaw giving power to increase the capital stock of the company by $750,000 was submitted and approved. The stock, it was decided, would be issued on a basis of one to two, so that present holders of two shares would be entitled to one in the new stock.

Hon. S. W. Parent has announced that the English and United States company, which has applied for certain water powers on the upper waters of the Saguenay River, Que., for the purpose of establishing calcium carbide works, will spend over a million dollars there if they obtain the privileges. His engineer is engaged in preparing a report for him on the matter.

The Canadian Niagara Power Company, which obtained a new franchise from the Ontario Government under which, according to the statement of Wallace Nesbit, the company's counsel, it is expected that power will be available for transmission to Toronto, has given a contract for boring test holes along the line of the tunnel it contemplates building on the Canadian side of the Niagara River.

H. Alabaster, Gatehouse & Co., 4 Ludgate Hill, London, E. C., proprietors also of The Electrical Review, announce that the 1900 edition of the Universal Electrical Directory is in course of preparation for its 19th annual issue in January next. This book is of great value, and those wishing to secure the insertion of their names in the forthcoming edition should not lose any time in communicating with the publishers.

In connection with the destruction of water mains by electrolysis the Engineering News, New York, recently recommends the use of wood in joining water mains instead of lead. In St. John, N.B., it has been the practice for nearly half a century to close the joints in city water pipes, not with melted lead, as in most other places, but with pine plugs. The experiment was tried in 1851, and again in 1857. On both occasions it worked so well that the same policy was pursued two years ago. The object in view was economy.

The proposed bylaw to raise $25,000 to establish a municipal electric light plant in Almonte, Ont., was defeated, Sept. 26th, by 38 votes.

The first meeting of the new directors of the Radial Electric Railway since the Cataract Power Company syndicate secured control of the road, was held Sept. 9th, and officers were elected as follows: President, John Patterson; vice-president, Hon. J. M. Gibson; treasurer, John Moodie; secretary, S. E. Malloch.

The Nova Scotia Electric Co. has been organized to supply electricity for lighting and power purposes for the whole of the Annapolis Valley, Nova Scotia. The following officers have been elected: President, Hon. F. W. Borden; secretary-treasurer, J. W. Beckwith, who with Captain H. H. Norwood, C. O. Foss, F. W. Clark, F. B. Wade and Allen Healy will constitute the board of directors.

The St. Catharines Cold Storage and Forwarding Co., Ltd., is replacing its direct current power service now in use in the warehouse, with a 15 h.p. two-phase S.K.C. induction motor. The current for this machine is supplied by the St. Catharines Electric Light & Power Co., which has recently installed in its power house a 200 k.w. two-phase S.K.C. generator for both lighting and power purposes.

At a meeting of the creditors of the Kay Electric Company, Hamilton, Ont., it was decided to wind up the estate, and Mr. Weyler, of the Packard Electric Co., St. Catharines, E. Brown and James Dickson, Hamilton, were appointed inspectors. The nominal assets are $2,312.24, made up of stock and book debts, and the liabilities $1,721.03, of which $637 are preferred claims. The unsecured creditors, it is believed, will get a very small dividend.

Brewder & McNaughton, contractors, have issued a writ in the High Court of Justice against the Metropolitan Electric Co., Ottawa, claiming $50,000 damages for alleged breach of contract and for wrongful deprivation of plant, materials and other goods and chattels. The writ is also for an injunction restraining the company from further use of the said plant. This is the outcome of the dispute which has been going on between the contractors and company which ended in the company taking away the contract from Brewder & McNaughton.

Guglielmo Marconi, the exponent of wireless telegraphy, who is now in New York, said to an interviewer: "The outlook for wireless telegraphy is bright, and the system is constantly being perfected. Messages have been flashed eighty miles, but I do not care to say what has been the greatest distance reached. The experiments have proved that the curvature of the earth is overcome, for in sending the message between stations 80 miles apart the earth curvature, which is over 1,000 feet, has been overcome. The station from which the message was sent was 70 feet high."

A syndicate has bought the Chats Falls at Fitz Roy Harbor, on the Ottawa River, on behalf of the Pontiac Mining Company. The falls are about 35 miles from Ottawa, and a minimum of 141,000 h.p. can be developed at low water and 600,000 h.p. at high water. The purchase was carried through by T. C. Bate, N. A. Belcourt, M.P., W. J. Poupore, M.P., P. Clark, Ottawa; Denis Ryan, St. Paul, Minn., and T. A. Darby, of North Carolina. These gentlemen bought the property as individuals, and are turning it over to the company. The falls, as mentioned some months ago in The Canadian Engineer, are in the middle of a highly mineralized country, and near two lines of railways.

At the annual general meeting of the shareholders of the Great Northwestern Telegraph Company the old board of directors and officers were re elected, viz.: President, H. P. Dwight, Toronto; vice-president, Adam Brown, Hamilton; directors, H. N. Baird, James Hedley, A. S. Irving, W. C. Matthews, Toronto; Richard Fuller, Hamilton; Hon. William McDougall, Ottawa; and Charles A. Tinker, New York; secretary and auditor, George D. Perry; treasurer, Arthur Cox. The financial statements presented showed a marked improvement in the revenue of the company over the previous year, and it was stated that the outlook for the coming year was still more hopeful.

Marine News.

Smith Bros., Quoddy, N.S., are building a steam boat 68 feet long for Wm. Butler, Yarmouth, N.S., to be completed November 1st.

Sheet piling is to be driven on both sides of the Burlington Beach canal, Hamilton, Ont., to such a depth that it may be dredged to a depth of 20 feet.

Isaac Radford, Buffalo, is arranging with J. Gaskin, Kingston, Ont., for boats from the latter for transferring a large quantity of iron ore from Three Rivers, Que., to Buffalo.

The Quebec, Hamilton & Fort William Navigation Co., which was incorporated a short time ago, has sent A. B. McKay to Great Britain to buy two 3,000-ton steel freight steamers for the lake trade.

The Richelieu & Ontario Navigation Co. will make a very interesting exhibit at the coming Paris Exhibition. Photographs of the fleet and the various hotels of the company, together with views of the scenery of the route will form part of the exhibit.

The record from Liverpool to Quebec was made by the "Canada" of the Dominion Line, which sailed from Liverpool 5 p.m., Thursday, October 29th, 1896, arrived Quebec 11.20 a.m., Thursday, November 5th. This still remains by almost 20 hours the fastest trip of any steamer to St. Lawrence ports.

The steamer "Delta," employed in carrying coal between Louisburg, C.B., and St. John's, Nfld., was reported wrecked at St. Mary's Bay, Nfld., Sept. 14th. She formerly belonged to the Cunard Steamship Company, and was 550 tons register. She was the second steamer to cross the Atlantic between England and Halifax.

The returns of the traffic through the Sault Ste. Marie canal from the opening of navigation on April 26th until Sept. 24th, show a considerable falling off. For the present year the number of vessels which have passed through the locks is 2,725, with a tonnage of 2,092,701, and a freight tonnage of 2,114,984. For the corresponding period of last year the number of vessels was 3,048, tonnage 2,211,899, and a freight tonnage of 2,463,058.

A new tug, "Robert Mackay," has been built for the Harbor Commissioners, of Montreal, by Carrier, Laine & Co., Point Levis, Que. The new vessel is a powerful looking craft, and has a speed of over eleven miles an hour. Her dimensions are as follows: Length between perpendiculars, 71 feet; length over all, 81 feet 9 inches; breadth, moulded, 17 feet 6 inches; depth, moulded, amidships, 11 feet 5 inches; draught forward 8 feet, draft aft 9 feet 6 inches. The tug is built of steel. The cost was about $8,000.

"Success has attended every service this season," said C. S. Gildersleeve, manager of the Richelieu & Ontario Navigation Company, in a recent interview published in a contemporary, "and the earnings are over $100,000 net, in excess of those of last year." He stated further that so encouraged was the company that other new steamers would be added to the western service, and to that between Quebec and Montreal. At present the boat-builders were congested, and it would take a year to get one new boat ready. During the coming winter the steamer 'Longueuil,' would be rebuilt, and the ferry service perfected as far as possible. The new steamer 'Toronto' had helped to swell the earnings, and only proved that the public appreciated first-class accommodation. The hotel department of the company promised to expand, as it, too, had proved highly successful. The new hotel at Murray Bay was 'under way,' and would, he expected, be ready by June 15, 1900."

Objection has been made by United States vesselmen to paying fees for the inspection of United States vessels running to Canadian ports, though the Canadian officials have been carrying out the law of Canada, whereby Canadian vessels were charged inspection fees. American vessels were treated in exactly the same way. For the past ten or more years the American Government has been in the habit of inspecting Canadian vessels running to American ports. The Canadian Government has repeatedly requested the American Government to accept the Canadian inspection in American waters in lieu of the United States inspection being accepted in Canadian waters, but this reciprocity had not met with favor. The margin of safety under the Canadian law is said to be much greater than that under the United States law. In the first place the steam boilers of Canadian vessels are not allowed to use within 25 per cent. so high a steam pressure as is permitted under the American inspection.

Mining Matters.

Geo. McIlraith's iron pyrites mine in Darling township, Lanark county, Ont., is now being worked.

Work at the Ostram nickel mine on the Calumet Island, Que., has been resumed by the English-Canadian Mining Co.

Gold has been found on the farm of Robert Grier, 4th line, Ramsay, Lanark county, Ont. An assay is said to show gold amounting to $8 per ton.

The mica mine discovered on the property of Robert Schnider, 7th concession, Sydenham township, Frontenac county, Ont., has been bought by G. Moriel, Kingston, Ont., who will work it.

The richest mica mine so far discovered in the Gatineau district, that of Father Guay at Gracefield, Que., has been sold to W. H. Sills, Chicago. A complete equipment of the newest machinery will be installed.

The Sailor mine, Camp McKinney, B.C., is sinking a vertical shaft by contract for 100 feet, and when that depth is reached a hoisting plant, which was recently ordered in this city from the Jenckes Machine Company, will be installed.

The first discovery of coal in the Boundary district of British Columbia, it is claimed, has been made by Robert Clark. The seam is said to average 25 feet in width, and is on the north fork of Kettle river. Jay P. Graves has bought a half interest, and will develop the property at once.

On the Minnehaha mine, Camp McKinney, B.C., a five-drill Ingersoll Sergeant compressor and an 80-h.p. boiler have just been installed. The plant is to be used to extract ore in sufficient quantities to run a 10-stamp mill which the company has ordered. There is considerable high grade ore in sight in the mine.

The Dunnville, Ont., Natural Gas Co. has been incorporated with a capital of $20,000. The provisional directors of the company to be J. Taylor, F. J. Ramsey, W. W. Krick, J. Norris, W. Shirton, W. D. Swayze, J. Parry, C. Shirton, T. Rice, L. Massecar, W. Bullock, J. E. Griffin and R. Bradford, of Dunnville, Ont.

J. Johnston, manager of the Crow's Nest Coal Co., Fernie, B.C., stated recently that 500 men were now engaged in the company's mines, that the mines were lighted by electricity, and the coal was hauled to the pit's head by electric motors. The company can produce 1,000 tons of coal every 24 hours, and when the coke ovens now being constructed are completed it will supply 300 tons per day.

Telephone connections have been made from Mine Centre Ont., to all the mines of the Bad Vermilion Lake group, including the Golden Star, Decca, Manhattan, Olive, Lucky Coon, Aria, Alice A., and many others. The Manhattan Gold Mining Company is installing a compressor plant, and fifteen additional stamps are being installed at the Olive mine.

The Iron Mask Gold Mining Co., Rossland, B.C., is enlarging its electric hoist and air compressor, and has placed an order with the Royal Electric Co. for a 120 k.w. S.K.C. synchronous motor. The first order received by the above company from the Iron Mask was for a 75 k.w. S.K.C. motor. This was found not large enough for the requirements.

W. R. Arnold of the Valley Worsted Mills, Providence, R.I., and David Sherwood, Rhode Island, were recently in St. John, N.B. They are interested in the Intercolonial Copper Mining Co., whose property is situated near Dorchester, N.B. The mine has been idle for 15 years, but the company intends to resume operations next summer. About $125,000 will, it is said, be invested in new machinery and buildings.

It is said the Dominion Coal Company will mine 400,000 tons this winter.

J. L. Bell, advocate, Quebec, has accepted the position of assistant gold commissioner in Yukon at a salary of $4,000.

G. W. Mitchell has just returned from the Peel River. He has made a good map of the river courses in the hitherto unexplored country lying between the Mackenzie and the Yukon rivers.

D. H. Beaton, Fort William, Ont., reports that the Johnson Nickel Mining Co., St. Paul, U.S., are doing extensive prospecting for iron with a diamond drill on the Canadian border near Gun Flint Lake.

George C. Hinton & Co., Vancouver, B.C., have placed an order with the Royal Electric Co. for a 10 k.w. multipolar generator, and the necessary wiring of lamps for one of their mining camps on Vancouver Island.

A fine strike of nickel ore is said to have been made in the Fort Steele district of East Kootenay. The claim is four miles from Fort Steele on Wild Horse creek. A wagon road runs from Fort Steele directly to the property.

An immense copper belt is said to extend from White Horse Rapids, on the Yukon River, to a point on the Dalton trail, forty miles from the Lynn Canal. It is over fifty miles in extent, and lies in British territory. In places vast masses of ore yielding $60 in copper to the ton are exposed.

W. H. and J. W. Wylie, Almonte, Ont., have a gang of men taking out hematite iron ore between White Lake and Calabogie, Renfrew county, Ont. Several car-loads will be shipped to the smelting works at Deseronto for test, and if found desirable the mine will be extensively worked.

Lord Ernest Hamilton is said to have bought the Florman quartz claims at Atlin for a quarter of a million dollars. The agreement binds the company which Lord Hamilton will organize, to put up a stamp mill of large size. The group is called the Anaconda group and embraces four ledge claims, aggregating 216 acres.

J. J. Durage, Duluth, Minn., has surveyed the water power of the Seine river, Ont., from Sturgeon Falls to McManus Falls, a distance of eight miles. There is a total fall in this distance of nearly 100 feet, of which 74 feet are in eight falls. It is feasible to construct power plants for the generation of nearly 3,000 h.p. Power might be furnished for the operation of the Alice A., Gold Bug, Emma Abbot and a number of other mines near by.

The iron mine at Ironsides, Que., on the Gatineau River, four miles from the centre of Ottawa city, and known as the Haycock mine, has been sold to J. O. Hibbert, until lately of the New York and Ottawa railway. The mine has an area of 300 acres, and the ore is of the best hematite. It was operated twenty-five years ago when smelting on a small scale was carried on, and extensive shipments were made, but the price having fallen operations were suspended.

The uncovering of a solid mountain of native ferro-nickel manganese at Durango iron mountain, Mexico, has created great excitement throughout the Republic, according to the statement of Harvey Kline. Tradition has it that this enormous mass of native metal is an aerolite that fell from the sky centuries ago. It is more than 300 feet high, half a mile wide and more than a mile in length, and is estimated to contain more than 500,000,000 tons above ground. It is worth $485 a ton. A rolling mill with two large blast furnaces is now nearly completed to work on this mass of native metal, and already five cars of ferro-nickel manganese have been shipped daily from Durango to the United States and Europe.

The announcement has been made that the Dominion Coal Company has made voluntary provision for sufferers through the late disaster at Caledonia as follows: For each widow a month's pay for the first year, and after that during her life, or while she remains a widow, $12 a month. Two dollars a month for children until they are each 13 years, and after that $4 a month for the boys until they attain 14 years, and $4 a month for the girls until they attain 16 years. In cases of single men who were supporting aged or infirm parents the latter are to receive $8 per month during life. Parents who were partially dependent upon their son for support will receive $4 each per month. The payments are to date from July 1 last and continue as above.

The statement of laboratory work done at the Ontario Government Assay Office, located at Belleville, which is conducted by the Bureau of Mines as an aid to the discovery and the development of the mineral resources of Ontario, shows that 277 determinations or assays were made during the month of August. These consisted of 232 gold assays, 14 for gold and silver, 19 for copper, 7 for nickel and 2 iron ores for partial analysis. Of these 168 determinations were done for the Bureau of Mines on which no fees were collected, while 109 were for the public on which fees aggregating $130.65 were collected. As the fees are about one-half the regular rates this statement shows that the prospectors and mining men engaged in development of properties are now aware of the advantages which the office affords. The office also reported on 30 samples sent in for identification, which consists of a description of the samples with the probable metallic contents and commercial value. The samples came from all parts of the province, the gold ores from the Seine River and North Hastings districts, while the copper and nickel ores were sent from the Sudbury and Parry Sound districts.

Dr. A. P. Coleman describes a specimen of hematite iron ore, which was taken from a deposit on the claim of E. V. Clergue of Sault Ste. Marie, which is about ten miles north of Michipicoten Post. It contains 60 per cent. of iron. The deposit, according to Dr. Coleman, has an area of 350 feet by 450 feet, although late exploration shows the length to be not less than 550 feet. The deposit rises to a height of 90 feet above the level of Lake Boya, into the waters of which it dips. So far as can be seen, Dr. Coleman says, most of the deposit is high grade ore. It possesses all the characteristics of hard brown hematite, many of the specimens obtained in it showing botryoidac forms, and a variety of beautiful colors. While the percentage of iron is high, there are only traces of sulphur and phosphorus. If the hill in which it appears is solid ore, which is almost certain, the quantity in sight above the ground line would be about 1,680,000 short tons, and if it goes to any distance below the ground line the quantity would be much more. The ore in sight alone, however, should produce 1,000,000 tons of pig iron, worth, at the present United States price, $15,000,000. Dr. Coleman says none of the adjoining locations have any important ore bodies in sight, but the same formation runs through them as in the Clergue mine, to a greater or lesser extent. Mr. Healy, of Duluth, who recently acquired these properties adjoining the Clergue mine, thinks the prospects are very good. To give an idea of the importance of the Clergue mine, it is sufficient to say that a blast furnace capable of smelting 200 tons per day, and working 300 days in the year, would occupy 28 years in smelting the ore in sight. As far as Director Blue of the Bureau of Mines is aware, it is the only important deposit of hard brown hematite in the country, and it very closely resembles the rich hematite ores supplied by Malta and Cuba. The deposit is so situated that the ore can be mined very cheaply—in fact it can be mined as an open quarry, and very easily and cheaply handled. The distance from the mine to the water's edge at Michipicoten harbor is only twelve miles, and docks are to be constructed at the latter point, where it can be put on board and delivered to the furnaces at Midland, Hamilton or Deseronto. A railway is now in course of construction from Michipicoten harbor to the mines, which is expected to be completed in time to ship out a quantity of ore this season. A quantity of ore will be sent to the new blast furnace at Midland, and Mr. Clergue is preparing plans for a new blast furnace at Sault Ste. Marie.

Personal.

T. H. Wiggins, C.E., has tendered his resignation as town engineer of Cornwall, Ont.

H. Townsend, contractor for the Coast Railway construction, died of cancer at his home in New Glasgow, N.S., Sept. 8.

P. S. Gibson, Willowdale, engineer for York township, has been appointed to a similar position by King township council, York county, Ont.

Mrs. Margaret Gartshore, widow of the late John Gartshore, the pioneer manufacturer of Dundas, Ont., died at her residence in Hamilton, Ont., Sept. 2nd. Mrs. Gartshore was 90 years of age.

Capt. Lesslie, assistant instructor of engineering in the Royal Military College, Kingston, has gone to India to rejoin his regiment. He is a graduate of the Royal Military College, Kingston, Ont.

Matthew Neilson, C.E., manager of the electric railway system of St. John, N.B., visited his Almonte, Ont., relatives when taking part in the Dominion Rifle Association matches, where he showed himself an able marksman.

Fred. T. Greene, Butte, Montana, has been appointed mining engineer of the War Eagle Gold Mining and Development Co., Rossland, B.C. Mr. Greene is a Canadian, being the son of W. A. Greene, of the W.G. & R. Co., Berlin, Ont.

Thomas R. Secord died at his residence, Port Colborne, Ont., Sept. 6th. Mr. Secord was inspector on the Welland Railway during its construction, but in April, 1861, he was appointed deputy superintendent of the Welland canal, which position he held until about two years ago.

E. Andrews, M.E., a graduate of the School of Practical Science, Toronto, who has been on the assay staff of the War Eagle Mining Co. at Rossland, B.C., for the past year, has gone to McGill University for post-graduate work in mineralogy, the facilities offered for study there under Profs. Harrington and Adams being unequalled elsewhere in Canada.

Canada can claim a share in the praise that is being given the steamship "Oceanic," as its designer, the Right Hon. W. J. Pirrie, is a native of Canada, having been born in the city of Quebec in 1847. After completing his education at the Royal Belfast Academical Institution, he devoted himself to engineering and shipbuilding. He is now chairman and principal of Harland & Wolfe, Ltd., and has designed and built some of the largest and fastest steamers afloat, including the "Majestic," "Teutonic." "Canada," "Cymric" and "Pennsylvania."

John W. Bell, B.A.Sc., lecturer on mining and metallurgy in the Faculty of Applied Science, McGill University, has resigned, and accepted a position with a large mining concern in British Columbia. His resignation is a loss to McGill, from which university he graduated in 1897, and with which he has since been connected in the capacity of demonstrator and lecturer.

Jas. Poole, chief accountant of the Goold Bicycle Co., Brantford, Ont., has received a similar position with the Canada Cycle and Motor Co., and a short time after the appointment received by express a very handsome and costly silver service, without any intimation as to who the donors were, although it is presumed it came from the employees of the Goold Bicycle Company.

The Fairbanks Co., Montreal, has made a contract with the Foster Engineering Co., Newark, N.J., for control for the Canadian market of their product, consisting of pressure regulating or reducing valves and pump governors. Howard C. Foster, a son of the manufacturer of these goods, has taken a position as salesman with the Fairbanks Co., and will give his time to these goods in connection with the Fairbanks steam specialties, which are already so widely known.

Surg.-Lieut. Bertram, whose fine work at the Bisley ranges was commented upon in the last issue of The Canadian Engineer, was given a royal reception on his return to the town of Dundas, Ont., Sept. 6th. There was a torch-light procession with several bands, and an open air meeting, at which addresses were read on behalf of the town council and of the officers of the 77th Battalion, who also presented a silver tea service, as did also the Victoria Rifle Club, Hamilton. The citizens of Dundas, Ont., presented a purse containing $400.

W. A. Carlyle, superintendent of the Le Roi mine, is said to have accepted the managership of the Rio Pinto mines in Spain, with a salary of $25,000 yearly, which is very much greater than his former salary in Rossland, B.C. Mr. Carlyle is a Canadian, being a native of Oxford county, and a nephew of the great Thos. Carlyle. At the time of his birth his father, Wm. Carlyle, now public school inspector for Oxford county, was principal of the Central school, Galt, Ont. Mr. Carlyle, who is a distinguished graduate of McGill University, was formerly inspector of mines for the Government of British Columbia.

Railway Matters.

The G.T.R. is building a new double track bridge over the Magog at Sherbrooke, Que.

There is a strong agitation in the northern part of Quebec to secure the extension of the Lake St. John Railway to James' Bay.

A charter is to be applied for for a new line of railway between Ottawa and Brockville as an independent direct connection with Brockville and with the Grand Trunk system.

R. A. Hazlewood, C.E., has surveyed the connection between the C.A. and O.A. & P.S. Railway, and the C.P.R. at Parry Sound. The distance is almost five miles, and the link will form part of the James' Bay Railway.

A bylaw to provide for the granting of a $20,000 bonus to the Lake Erie, Tilsonburg and Port Burwell Railroad for an extension for the road from Tilsonburg to Ingersoll, was carried by a large majority in Ingersoll, Ont., Sept. 20th.

After many months of surveying and the expenditure of much money, the C.P.R. engineers have at last discovered a feasible route for a railway over the divide between the Kettle and Okanagan River valleys to the south of Camp McKinney.

The Midland Railway contractors in Nova Scotia are pushing their work, says The Truro News. The rails are now laid up to the Shubenacadie river, and ballasting is going on day and night. An electric light plant has been installed in the ballast pit at Stanley, so that night work can be pushed with redoubled vigor.

The Jenckes Machine Co., of Sherbrooke, Que., have built one of the George E. Smith power rail bending machines for Ross, Barry & McRae contractors, for use on the construction of the Great Northern Railway. The machine will be driven by a 10-h.p. Dake engine, the steam being taken direct from the locomotive.

The Algoma Central Railway has 500 men employed in the construction of a twelve-mile section of the line from Michipicoten Harbor to the iron mines owned by the company. The exceptional activity of the company, despite the scarcity of labor, is explained by the fact that a contract has been entered into with the Midland smelter for the supply of iron ore this fall. The rails will, it is said, be laid by November 1.

The Canadian Pacific Railway Company has received advices to the effect that the work of construction on the Columbia and Western Railway is now almost completed, and it is expected that trains will be running into Midway before winter. This road, which has been constructed by the Canadian Pacific Railway Company, opens up the famous Boundary Creek mining country. It runs from Robson, on the Columbia River, to Midway, on the Kettle River, a distance of 100 miles. T. G. Shaughnessy, president of the Canadian Pacific Railway, said recently: "The grading of the road into Midway has been completed, and there remains only some twenty-five miles of iron to be laid before we shall have our trains running into the town of Midway. The work on the big tunnel, 30 miles west of Robson, where we have pierced for 3,000 feet the side of a mountain, is not quite completed, but the completion of the work there will not prevent the running of trains from Robson to Midway this autumn. In addition to the main line, we have constructed some thirty miles of sidings along the line into mining camps, where the development has been sufficient to warrant us in going to that expense. This road is, by all means, the most expensive the Canadian Pacific has ever constructed. The country throughout the entire distance is exceedingly difficult, and the engineering difficulties very great. The entire line has cost the company in the neighborhood of $40,000 a mile, or a total expenditure of nearly $4,000,000 for 100 miles of line. The company received no subsidy. The Boundary Creek country promises to be one of the richest mining countries in British Columbia, and though the road has cost the Canadian Pacific a very large amount of money, there is no doubt that the business over the road, as soon as the mining properties along the line are opened up and developed, will be very large."

The Rainy River Railway will open up a great extent of rich mineral country. Commencing at Stanley, up to which point it has running powers over the Port Arthur, Duluth & Western Railway, the line runs close to Kakabeka Falls, a vast water power, and proceeds through the east end of the Matawin iron range, which is twenty miles long, of which two-thirds is soft hematite, and the remainder, at the western end, magnetic. Skirting the Shebandowan and Kashabowie lakes, the line then passes through a copper region, the most known mine in which is the "Tip Top," having a vein of a hundred feet wide; thence it runs close to Moss township, where there are several gold locations, not at present being developed. The line next passes close to Lac des Mille Lacs and Partridge Lake, twelve miles to the south of the Saw Bill mining region, running nearly parallel to the Ati-Kokan iron ranges, a distance of twenty miles. It is stated upon excellent authority that here is the largest iron deposit in the world, there being in one place 2,000,000 tons of iron ore in sight on a plot of 160 acres. The Seine River waters are next reached, which will give ready access to the mines, and here there are many valuable water powers. Running along the Seine River valley, the line goes near to Bad Vermilion and Little Turtle lakes, where it will cheapen supplies for more than a hundred prospects and mines, the principal of the latter at present being the Golden Star and the Olive. It next runs along Rainy Lake, crossing the western arm of the same on a succession of six islands, two miles west of Pither's Point, necessitating the building of five bridges. Between Pither's Point and Fort Frances is an excellent site and prospect for a large city, the Couchiching Falls being estimated to supply a water power of fully 50,000. From Fort Frances the line runs along the Rainy River, where there is a large area of fine agricultural lands, and reaches Hungry Hall, at the river's mouth. Here the line leaves Canadian territory until it reaches Buffalo Bay, a distance of 35 miles, and enters Manitoba at the latter point. The land is well wooded from Buffalo Bay to Winnipeg, and considerable revenue has been derived from this source to assist the 60 miles of railway already constructed. Besides the subsidy proposed for this Rainy River Railway, the Government has included a subsidy in the estimates for 40 miles of the 160 miles of the proposed Central Algoma Railway, and if these two lines should be built, as now seems almost certain, they will not only help to develop the interior of New Ontario rapidly, but may be expected to act as great feeders to the St. Lawrence route.

THE STOKER CASE.

Our readers will remember an action taken by the General Engineering Company, of Toronto, against the American Stoker Company, of New York, and the Dominion Cotton Mills Company, of Montreal, which has been pending in the Canadian Courts for more than a year past. This was a suit brought by the plaintiffs against the two defendant companies for damages for infringement of the Jones Underfeed Stoker patents, and for an injunction to restrain the defendants from using these stokers in Canada. The case was regarded as a very important one to manufacturers, and both parties to the suit had retained eminent counsel. J. L. Ross, of Rowan & Ross, Toronto, and C. A. Duclos, of Atwater & Duclos, Montreal, appeared for the plaintiffs, while Donald McMaster, Q.C., of Montreal, and Gifford and Bull, of New York, represented the defendants. The trial lasted four days. The action was a test case, the object of which was to determine the validity of the Jones' patents, not only in Canada, but for the whole continent of America. The judgment of the Exchequer Court, in which it was brought, was a very strong one, and Mr. Justice Burbridge upheld the validity of the Jones patents, and granted the injunction asked for, with damages. These damages were not fixed at the time, but would depend on the number of the defendant's stokers set up in Canada. The total damages would probably reach $10,000, or over. The defendant's, however, are continuing the litigation in another form on a point raised by them since the previous action was decided, and have obtained a stay of proceedings in the main action by putting up a bond in the American Surety Company for $5,000. The result of the action will be of considerable interest to owners of Canadian patents in general. Up to the present the General Engineering Company have succeeded at every stage of the legal contest.

—One of the oldest bridges in Europe is soon to disappear, under the demand for better navigation of the river it spans. This is the stone bridge, with fifteen arches and a total length of 994 feet, built across the Danube at Regensburg (Ratisbon), in Bavaria, by Duke Henry the Superb, in 1135-1146.

WANTED—Young man familiar with installing and repairing electric recording meters. Give particulars of experience. Only hustlers and first-class penmen need apply. Advancement if satisfactory. Address "WATT," Canadian Engineer, Montreal.

WANTED—A First-class Mining Foreman, who has had experience in Galena, Zinc and Silver Mining. Send references and rate of wages expected to P. W. RESSEMAN, 31 Central Chambers, Ottawa, Ont.

FOR SALE

A good Water Power, 500 horse, situated one-half mile from railway, every facility for making siding to power. Address

SANITARY NECESSITIES.

BY W. M. WATSON.

I have lately received a couple of clippings out of the Montreal "Witness," from a friend, together with a mild request that I should express my opinion on the facts they contained, publicly if I had the opportunity. Probably if I fully complied with the gentleman's wishes, I might place myself in a similar position to that of a plaintiff, who was addressed in the following words, by a late chief justice in England, when appealing the heavy damages that the jury had inflicted upon him for libel, viz.: "My experience in this court of such cases as yours is, that the law is too often used to punish the person who is unwise enough to speak the truth."

The clippings give the remarkably high death rate in Montreal, comparing the figures to the death rates of similar large cities, which are about one-half as heavy. If Dr. Reid, who prepared the statistics, would go a little farther and tell the public the actual death rate of the English-speaking citizens, and that of those who speak other languages, a little more light would be shown to an outside reader. Let Dr. Reid turn up a Montreal "Star," dated November 4th, 1885, and he will find that the statistics prove that the mortality for October in that year was 1,391; out of this number 1,286 were French-Canadians, 65 others belonged to the Catholic faith, and only 40 out of the whole number were English-speaking Protestants. That was the time when the preventable disease of smallpox was epidemic in Montreal. Between the fine houses of Montreal, among the wealthy, and those of the very poorest of the working-class is found a very unnatural gulf. The first-named class is allowed from 600 to 6,000 cubic feet each of enclosed air space to live in. They are heated in cold weather, by that healthy apparatus called low pressure, indirect, hot water heating, which gives them a splendid ventilation, as well as a warm, soothing temperature. They enjoy the best sanitary appliances, and take daily baths. They are surrounded with appointments that are pleasing to the eye, and are served at table by expert cooks. There is, within one mile, a large manufactory of white lead, etc., the men who do the work and benefit the general public live near the works, in houses built over swamp-holes; they have not a single thing within sight of their windows that has a pleasant effect; they possess no gardens or flowers. The rooms and rear yards are so small that in place of having the regulated amount of 600 cubic feet per head of interior living space, they cannot measure more than 200. In winter they crowd together in one room, with every crevice where the air can pass in and out of the room to change the sickening atmosphere pasted up with paper. Their heating is done by the air passing over the red-hot plates of an iron stove, which destroys the air that the inhabitants should be breathing, and the inmates are gradually destroying their own respiratory organs and poisoning their blood. The poison these workmen are liable to, when working, gives them but a short time to live, but this time might be largely extended, if the city authorities would do their duty. Why should the street opposite the doors of the poor dwellings be ankle deep in mud and festering garbage. The area around their houses should be considerably larger than at present, and the houses built on clean and wholesome foundations. Could not the City Council afford to give such working-men good swimming baths in each district, handy to get at, and provide for everyone to enjoy, at a small, but probably paying-price, a good wash. I know that many people will remain in a stifling room with apparent enjoyment, that other people would not tolerate one hour; and this is probably the reason why our French brothers suffered so badly in the year 1885 from smallpox, and are at present in a lesser degree doing the same each year. This is not the fault of themselves, or anything in their social or religious life, but of the shameful and openly corrupt city government. But while it pampers the class that is wealthy enough to pamper itself, it cares nothing for the poor, and still allows the barbaric system of earth cesspools to do duty for privies, to foul the soil the people live on, and to emit a united sickening odor into the air the unfortunate inhabitants are compelled to breathe.

The editor of the "Witness" tells us that the water supply is bad, that foul sediment is stored in the reservoir. Now the motto for all waterworks is to keep scrupulously clean the interior of all water pipes and tanks containing drinking water; I believe that there are no clean-out valves on the water mains of Montreal, therefore, the mains cannot have been properly cleaned since they were laid down. We are told that there is putrid matter or foul sediment in the bottom of their reservoirs; if so, then there is similar foul deposit in all the water mains. Why does not the "Witness" call for pipe cleaning as well as the reservoir cleaning? Simply because they cannot see inside the pipes, but can see inside the open reservoir. The pipes have been down a number of years, and the foul stuff in the bottom may be impregnated with disease germs, and will grow worse as time passes.

The end of a very long line of water pipes should be cut, and a full-sized valve placed on it, then a good drain made to receive the waste water; when this is done then leave the valve full open and open the turn-off valve at the intersection with the trunk water main quickly, so that it will cause a great commotion inside the water mains, with the air the mains will then contain, so that the dirt will fly before the body of rushing water to the wash-out valve, and by the time the body of water reaches that point, the interior of the pipes will be clean, and comparatively only a few gallons of water used. If the pipes of Montreal were laid on the circulating system, they should be divided at prominent places where they will be able to flush the longest length of main pipe at one time, in a similar way, as above described. The next question is, why should water, which contains such foul sediment as the "Witness" complains of, be allowed to enter the water mains, Montreal having the very best facilities to hand to filter the water, the cost of which need be no more than one cent per head to build and manage. I believe I can tell the "Witness" where to find the key to the whole trouble that causes the great sacrifice of human life in Montreal, and that is the disgraceful way in which public officers are appointed. It is no secret that positions are sometimes sold at good prices, that men are engaged who know nothing of the business they are appointed to fill, nor do some of the appointees care one cent for the general welfare of the public, who pays their wages. Montreal may have the best and the most expensive appliances put down to perform its public works, but they quickly deteriorate after their completion for the need of reasonable intelligence being displayed by some of its officers, in charge, who are void of skill. In October, 1898, this paper published my description of the Montreal incinerators, and it proves what poor mechanical assistance the city pays for. It is some years since I looked over the water-works, and cannot speak as to any present details, but the complaints named by the "Witness" could be easily and quickly corrected.

The York machinery Co., composed of W. H. Stubbing, J. G. Nicholson and J. D. Bird, has started business at 833 Yonge street, Toronto, as manufacturers of laundry machinery. The firm is now making power framing machines of all kinds, hydro extractors, etc., and will make special machines to order for other lines of trade. Mr. Stubbing, the manager, reports that his shop has been very busy ever since the shop was opened.

SOUTH AFRICA, ITS PEOPLE AND TRADE.

CAUSES OF THE BOER WAR.

ARTICLE II.

In our article last month, a brief sketch was given of the beginning and rise of the European communities in South Africa. The history was brought down to the annexation and retrocession of the Transvaal. As there exists a great deal of misconception about the causes of the present war, we shall endeavor to review the main facts.

What led to the annexation of the Transvaal? It was not lust of gold, for only small alluvial diggings had been found as yet, and the great gold reefs of Johannesburg were then as little dreamt of as the Klondyke of Canada. It was because the Republic was bankrupt, the Boers in many districts having refused to pay any more taxes, the country reduced to a state of anarchy by the incapacity of its administrators, by factions bitterly antagonistic to each other, and threatening civil war, and the failure of the Boer commandos to subjugate the native Chief Sekukuni, who was bringing other native tribes down upon the territory, the principal danger being threatened by the Zulus, under Cetywayo. This renowned Zulu King was anxious to pay off old scores with the Boers, who had constantly encroached on his territory, and frequently captured and enslaved his people and robbed them of their cattle and lands. The British Government might have allowed the Boer Republic to find its own way out of its financial difficulties, but when it came to their relations with the natives there was danger that once the Zulu King had overrun the Transvaal, with his 40,000 warriors, he could not restrain his army at that achievement, but it would then turn upon the British colony of Natal, which was neighbor to both, and which then had a white population of only 30,000, against a native population of 300,000. Under these circumstances, and considering that a petition for British intervention had already been signed by 3,000 out of 8,000 of the voters of the country, Sir Theophilus Shepstone, who had been authorized by the Home Government to act as he thought wise, annexed the country, without any force other than a personal escort of twenty-five mounted policemen. The British then took in hand the conquest of Sekukuni, which the Boers had failed to achieve, and then had to deal with Cetywayo, who, robbed of his revenge upon the Boers, now turned sullen towards the British. The next act in the drama was the great Zulu war, which was fought with no help from the Boers, except that given by a single family, Piet Uys, and his sons. These people, forgetting their rescue from certain destruction at the hands of the Zulus, no sooner found this dreadful menace removed, than they began to agitate against British rule. As stated before, they had one real grievance in the dilatoriness of the Imperial Government in granting them a local legislature; but this at last was being framed when rebellion was brought about through the enforcement of taxes, which the Boers refused more obstinately to the British than they had done to their own authorities.

The Government Treasury notes or "blue backs" then sold at a shilling, or say five cents on the dollar, while the salaries of the civil servants were three months in arrears.

These papers have been issued in pamphlet form, containing a glossary of Cape Dutch and Kafir words and phrases in common use. Biggar, Samuel & Co., 62 Church Street, Toronto. Forty pages. 10 cents.

In this rebellion they were led by a man, who, when the history of that land comes to be written, will be set down as the evil genius of the Dutch race in South Africa—Paul Kruger. This man, who was born a British subject in the Cape Colony, first came into prominence among his countrymen as a hunter and fighter—a fighter first against the Kafirs and then against his own people, as well as the English, whom he hates as cordially as the British sailor of Nelson's day did the French and Spaniards. It seems curious that a man of Kruger's pretenses to piety should be so tenacious of liberty and natural rights for himself and his fellow-Boers, and yet refuse the most elementary rights to British people in his country; and that he should see nothing but iniquity in Dr. Jameson's quixotic dash to rescue the Outlanders from misgovernment, and yet see no wrong in his own invasion of a friendly State with no better motive than a lust of power. Some forty years ago, at a time when the Transvaal and the Orange Free State (a neighboring Republic, composed of his own fellow-countrymen), were at peace, Paul Kruger formed a plot with M. W. Pretorius, another Boer leader, to overthrow the government of the Free State. While Kruger invaded the country, at the head of a commando, inciting the Free State Boers to rise, as he proceeded, Pretorius was set to instigate the Free State natives to revolt. The Free State forces were, however, brought together in much quicker time than he anticipated, and when Kruger saw himself confronted with double the number of cannon his own force had, he discreetly withdrew.

That Kruger's intrigues during the days of the first Republic were a cause of the country's troubles is shown by the statement of the last President, Thomas Burgers,* who, referring to the events that led up to the annexation, said: "Fruitlessly did I press upon him (Kruger), the fact that by showing how our danger lay in want of unity, the British Government would have cause to step in, on the ground of humanity, to avert civil war, and to present a general rising of the natives. * * He would not hear of retiring. Had I not endured in silence, had I not borne patiently all the vile accusations, but out of selfishness or fear, told the plain truth of the case, the Transvaal would never have had the consideration it has now received from the British Government. However unjust the annexation was, my self-justification would have exposed the Boers to such an extent, and the state of the country in such a way, that it would have been deprived both of the sympathy of the world, and the consideration of English politicians."

After the annexation, he was appointed field cornet (a position corresponding to our sheriff, but including also the duties of tax collector and other functions), of his district, at a salary of £200, which in those days was a good income. By false representations, however, he drew £300, or what came to the same thing, withheld tax moneys to that amount over his salary. The administration called upon him to make good the amount, but he did not do so then, or since. He only met the Government's request by demanding an increase of salary! The correspondence in the case is on record. How much the consciousness of this fraud had to do with the intrigues he engaged in against the British Government, it is hard to say. At all events, while holding an office under the British Government, he was engaged in agitations against it, and became the leader in the armed rebellion that followed. After the British defeats in the skirmishes at Laing's Nek, Majuba Hill and Ingogo, and while British reinforcements, to the number of 10,000 men, were gathered, the Gladstone Government stayed the sword-arm that was ready to strike back, and an armistice was arranged, followed by the convention of 1881, by which the Republic was restored, subject to the suzerainty of the Queen. By this instrument, the right of internal self-government was given to "the inhabitants" of the Transvaal, without prejudice as to nationality, and in the discussions by which the intent of its provisions was explained, Mr. Kruger distinctly declared that all would be put on an equality, as regarded the franchise and other rights. These discussions were taken down at the time, and form part of the records in the colonial office. At that time the Boers were in a large majority, and it is possible Kruger might have kept faith had the population remained thus, but Englishmen began to come to the country in greater numbers, and in 1886 the discovery of the now celebrated Witwatersrand gold fields brought people from all quarters of the globe, until the alien or outlander population, which of course included Englishmen, outnumbered the Boers. Kruger had from the first aimed to keep all power in the hands of the Dutch, and hence began the evasions and trickery by which the plain intentions of the negotiators of the original convention were to be thwarted. His ambition did not stop here. He purposed the formation of a great military state, which would centralize the Dutch influence in South Africa, and establish a Dutch republic extending from the Cape to the Zambesi, with Pretoria as the capital. For a long time this ambition, though steadily pursued, was concealed, and even now there are many well-informed public men in England and America who have either not grasped the situation or refused to believe the designs so steadily pursued by this cunning trickster. The people of the Orange Free State, under the misguiding influence of their present head, President Steyn—a third-rate attorney, possessed of none of the commonsense statesmanship of the late Sir John Brand, who so wisely guided the little State for twenty-five years previously—were easily led into these designs, and in the Cape Colony, the widespread ramifications of the Afrikander Bond—a sort of granger organization, having for its motto: "Africa for the Afrikanders"—afforded good ground to work upon, as its membership was almost exclusively Dutch. The plan, as regarded Cape Colony, was to overturn British authority gradually, allowing Britain to retain the

* In the course of his last address to his Volksraad, President Burgers said: "I would rather be a policeman under a strong government than the President of such a state. * * You have ill treated the natives, you have shot them down, you have sold them into slavery, and now you have to pay the penalty. * * The fourth point which we have to take into account affects our relations with our English neighbors. It is asked, what have they to do with our position? I tell you as much as we have to do with that of our Kafir neighbors. As little as we can allow barbarities among the Kafirs on our borders, as little can they allow that in a state on their borders anarchy and rebellion should prevail. * * To-day a bill for £100 was laid before me for signature, but I would sooner have cut off my right hand than sign that paper, for I have not the slightest ground to expect that when that bill becomes due they will be a penny to pay it with." President Burgers—who left the Transvaal broken hearted, not because of the annexation, but because of the intriguing which brought about the condition of things rendering that step inevitable—just before he died left a statement of the case for the benefit of posterity, in which he shows how Kruger plotted with the annexation faction in order to oust Burgers and get the presidency for himself. Kruger overdid his part, but though his ambition was balked for the time by the annexation which he did not count upon, he continued his intrigues against the British with the result which history tells.

naval station at Simon's Bay, and a certain "suzerainty," which could be strained to the breaking-point as time went on. Steyn, the Free State president, with his usual lack of diplomacy, gave a plain statement of these designs in a speech just a year ago, and anyone who studies the wording of most of Kruger's recent despatches and his replies to the enquiries of American and other newspapers, will see how he claims to act as champion of the whole of South Africa, though the difficulty is supposed to be with the Transvaal only. It was made plain to the British element in South Africa, and to the Home Government, that Britain must either make good her claim of paramountcy or give over the rule of South Africa to the Boers. As one of the Boers put it, there could not be two "bosses" in South Africa, and it became a question, which was it to be, Boer or Briton?

In pursuance of his policy of Napoleonizing South Africa, President Kruger, at the head of a delegation of three, went to London in 1884 to attempt to get a release from all semblance of British control, and to get a formal confirmation of the encroachments he had been making on independent native tribes since the convention of 1881. He represented to Lord Derby, the Secretary of State for the colonies, that his burghers were discontented under the existing convention, which they felt implied interference with their internal affairs. The deputation drew up a draft of a new convention, in which the name of the Transvaal was changed to the "South African Republic," and in which the British suzerainty was expressly abolished. In discussing this draft, Lord Derby politely, but firmly, informed the deputation that "neither in form nor in substance was it such as Her Majesty's Government could agree to;" but that as the paramountcy of Great Britain was an obvious fact, and did not require a document to establish it, he had no objection to satisfying the susceptibilities of the Boers by accepting the change of name, and by omitting any specific use of the word "suzerainty," which Kruger had said was offensive to them. And so, clinging to the letter of this change, Kruger built up his claim that the Transvaal was now a "Sovereign International State," though the new convention of 1884 distinctly prevents the Transvaal from making any treaty with a foreign power without the consent of Great Britain. Without trying to define the term "suzerainty," plain men will question the "sovereign independence" of a country whose autonomy was given as an act of grace, and which could not make its own treaties. But even if there were no suzerainty, the conduct of the Boer Government had rendered it liable to be called to account in a dozen ways under common international law.

Some people ask, was not the Boer Government justified in its recent policy, by the Jameson raid? The answer to that question is that the Jameson raid was the result of Boer tyranny and misrule, and not the cause of it. Had Kruger treated the Uitlanders as white men with natural rights, and had he not laid on burden after burden, and taken away right after right, with studied hostility towards British subjects in particular, there would have been no Jameson raid. The educational restrictions, the arming and fort building, the prohibition of public meetings, and the iniquitous press law, and other grievances, all preceded the Jameson raid. The people of Johannesburg and other Uitlander centres began to despair of any action from the British Government, and yet, while agitating persistently for their rights, the majority of the members of the "National Union," formed at the time to obtain redress for the people's grievances, publicly and privately assured the President that they had no desire to upset the republican form of government. And there is complete evidence that these sentiments were genuine with the Uitlanders at that time. Dr. Jameson's brave, but quixotic raid, as it was carried out, put the people of Johannesburg in a false position, and they have been unjustly charged with cowardice. It is not denied by the National Union leaders that an agreement was made with him to come to their aid. But after smuggling in 3,000 rifles, the leaders found that more had to be done to make the rising a success—for it was intended to seize Pretoria, whose forts, then under repair, were exposed and ill-garrisoned—and so they sent word to Jameson to wait on the Bechuanaland border till they notified him. Their object was not merely to

Scene—Market Square, Johannesburg.

become better equipped for the struggle, but to declare to the world that the struggle was their own, and not brought about through an invasion. They proposed to have a new flag, so that there should be no question of the independence of the movement. Dr. Jameson, however, became impatient, and appears to have disregarded either the requests of the committee or the warnings of the Imperial Government, who wired him as soon as they heard of his intention. The reader will remember how his force of 400 or 500 men were caught by a Boer force of three times his number before he reached Johannesburg, and compelled to surrender, the leaders in the movement at Johannesburg being unaware of his approach till too late to do anything. These leaders were arrested, and, as we know, heavily fined, the fines aggregating over a million pounds, and were bound over for three years not to take any part in the politics of the Transvaal. Their tongues were, therefore, tied, and hence the false impression that has been current regarding this affair. With his characteristic cunning, Kruger sent, as mediators, three men in whom the Johannesburgers had faith, and by promises of reform, made on his behalf through them, but which he had no intention of keeping, the people were induced to lay down their arms, hoping for redress at last. The President saw that the reformers had lost the sympathy of the outside world, through Dr. Jameson's mistake, and he took the fullest advantage of the fact. He at first pleaded for delay in the execution of the reforms till the excitement of his burghers should be allayed, and when this plea was somewhat worn by time, he repudiated the promises made to the mediators. An ever-increasing revenue, squeezed from the gold fields, enabled him to add to his forts and armaments, and the Jameson raid furnished the excuse that had been wanting before. In the case of Pretoria, the capital and centre of Dutch influence, the guns were mounted pointing outward; in the case of Johannesburg, the Uitlander city, they were placed so as to bear upon the town itself. Taking advantage of the sympathy naturally aroused in the Orange Free State, he drew that republic into a formal alliance by which it bound itself to join the Transvaal in any war that might arise. Before the Jameson raid, official Boerdom was insolent enough in its dealings with aliens, but after the raid, matters grew worse.

ENTER THE STANDARD OIL COMPANY.

Many of our good friends in Petrolia seem to have taken our reference to the Standard Oil Co.'s doings in Petrolia as a reflection upon the policy of the town authorities. This is shown by the letter from Petrolia in another column. Nothing could be farther from the writer's intention. We understand that the first deal by which the great oil monopolists obtained possession of Rogers, Fairbanks & Co.'s refinery was accomplished before the people of Petrolia were aware of it, and even if they had been they could not have prevented it. When the Imperial Oil Co. of Petrolia at first declined to sell out, the Standard Oil Co. took indirect, but none the less effectual means of getting their grip on the Canadian oil trade. They not only obtained from the Canadian railways a discrimination in freight rates against Canadian producers, but induced the Dominion Government to permit the importation of oil in ship tanks and cars. Before this, petroleum and its by-products had to be imported in cans or cases of not more than fifty gallons, and duty was charged on the cases. Inspection was also required which so restricted the imports as to give the Canadian refiner at least a fighting chance. When the Standard Oil Co. sought to break down these barriers deputation after deputation from Petrolia and other oil centres went to Ottawa, showing that such a change would ruin the Canadian oil trade as an independent industry, and would sooner or later deliver the business into the hands of the American monopolists. Their appeals were unavailing, but the prophecies were speedily fulfilled; for when the Imperial Oil Co. found itself in the ditch it sold out to the Standard, and the other small refineries had to follow.

The discrimination made by the railways in favor of the American corporation has been gratefully rewarded by the withdrawal of as much of the oil transportation business as it can divert to its own vessels. Once having become possessed of the Canadian oil business the Standard Co. could not be blamed for piping its crude oil from Petrolia to Sarnia, because with the facilities of shipping in tanks which the Government has given it a great saving could be effected by having its works along the water front at the Detroit River. As to the increased price which the Standard Co. is paying for crude oil, the fact will not be lost sight of that the price the company now charges for refined oil, gasoline, benzine, etc., has been advanced about ten times the proportion of the advance in crude oil. However, it is assuring to know that the enterprise of Petrolia's citizens is carrying the town ahead in spite of fate.

AMERICAN STEAM WAGONS.

Aside from the Serpollet system of flash boiler steam engines for light vehicles, which is successfully used in European countries, steam power was used exclusively for freight wagons and heavy constructions of other descriptions until a number of New England men, mostly engaged in other forms of machinery manufacture, evolved designs of boiler and engine which have made steam available for the lightest class of road wagons. By the success of their experiments they created a new type of light vehicle, which is characteristic for this country, and is already commanding intense interest in Europe. George E. Whitney, of Boston; A. T. Cross, of Providence; William B. Mason, of Milton; The American Waltham Manufacturing Co., and the Waltham Manufacturing Co., both of Waltham, and the Stanley Brothers of Newton, were the pioneers in these improvements of steam engines, closely followed by others, who are all indebted to the early experiments of S. H. Roper, who commenced his experiments with light steam engines over twenty years ago, and continued them until his death in 1896. To this common origin in ideas, says The Cycle Age and Trade Review, may be traced a certain sameness in construction of the engine part of the various wagons produced, but notwithstanding this partial similarity, each of the patterns has a pronounced individuality due to the great variation in running gear and details which are of the greatest practical importance for the management and operation of the vehicle.

Whitney in his experiments with yacht boilers found that the single vertical tubular boiler, with flues 26 diameters in length, produce more steam per pound of boiler than any other form of steam generator with which he experimented, and he has adopted as standard this ratio of dimensions. The dimensions of the boiler are: Total height, 20 inches, with a body diameter of 16 inches. Whitney uses copper tubes ½-inch in diameter, and about 300 in number. The boiler shell and fire-box are of steel, about 1-10-inch in thickness, and the completed boiler, which weighs about 85 pounds only, is tested to 500 pounds hydraulic pressure. The steam pressure used is not high, only about 125 pounds commonly.

In Mason's wagon the same style of boiler is used as in the Stanley and American Waltham wagons, the design being

Stanley's and the work Mason's. It is in most respects similar to Whitney's, but does not have the cylinder within the steam space of the boiler as has the latter. The Mason frame consists of a girder of steel tubing at each end, supporting the axles and connected underneath by two lattice braces, each formed of two crossed rods secured at their ends to the front and rear girders, and fastened together at the crossing. The upper corners of the two girders are joined by two composite side-bars, the wagon body being secured to these side bars by clips. The general scheme of the motive part of the Mason wagon is to locate the vertical boiler under the seat, and to pivot to the front side of the boiler a frame carrying a pair of piston valve, link motion, simple, steam engines, cylinders 2-inch bore by 3-inch stroke, working downward on cranks at 90 degrees. Mason uses a 12 pound flywheel on his engine shaft, with a view to equalization of torque when cutting off very early. Besides the flywheel the crank shaft carries an 8-tooth sprocket, from whence a Baldwin separable cycle chain leads to a 32-tooth sprocket on the compensating gear case on the rear axle. The rear axle is not divided, a sleeve being used to transmit power to one of the rear wheels. To secure a ready chain adjustment, a right and left threaded strut is pivoted to the compensating gear yoke, which forms a part of the rear axle support, and reaches forward to the engine frame. As the engine and boiler are carried on the wagon body springs, this screw strut requires a universal jointing to accommodate the variations in the relative positions of the engine crank shaft and the rear axle. The engine frame is pivoted on a steam admission located a short distance to the rear of the mid-point of the piston travel, hence the entire fabric of the engine frame and the engine has a free pendulum movement on the tri-union, enabling the driving chain to be very easily adjusted to a nicety. The firing of the Mason boiler is controlled by the use of a regulator acting on a diaphragm actuating the fuel admission valve. The gasoline is carried in a copper tank under 20 or 25 lbs. air pressure, maintained with a hand operated air-pump. This air pressure drives the fluid gasoline into a horizontal vaporizing tube, reaching entirely across the fire-box, close to the top of the burner. There is no valve between the gasoline tank and the vaporizing tube, and the fuel supply regulating valve is placed between the vaporizer and the burner, and acts on the gasoline vapor, not on the fluid before vaporizing. When the pre-determined boiler pressure is reached the regulator closes the fuel admission valve completely; to avoid the total extinguishment of the fire, a very small by-pass opening is provided around the fuel valve, this by-pass admitting vapor enough to the burner to keep the burner lighted and to keep the vaporizing tube hot, so that as soon as the boiler pressure falls the fire will be automatically increased without any attention on the part of the driver. When the regulator reduces the fuel supply it also opens a large area of cold air supply to the fire box of the boiler, and thus instantly checks the generation of steam, so that the safety valve never opens to discharge any steam into the open air, which is of very great importance, as this avoids an emission of visible steam, and also avoids a waste of boiler feed water, both very desirable points. The gasoline is carried in a cylindrical tank, located well forward, under the foot-board. The water tank is in the rear of the boiler. The boiler is clothed first with sheet asbestos, 1/8 inch thick, then with hair felt 5/8 or 3/4 inches thick. The tanks are of sheet copper. The smoke bonnet leads horizontally to the rear, and has an upwardly directed rectangular opening or smokestack, not more than an inch high, projecting a very little above the rear body cover. This smoke discharge is supposed to be of use when the wagon is standing still and the fire is burning. The smoke-stack is also carried downward and to the right side, and terminates in a downwardly opening, cylindrical nickel-plated smoke-stack, extending about 10 or 12 inches below the bottom of the wagon body. There is no damper in this smoke duct. The exhaust pipe is carried across the top of the boiler inside the smoke bonnet, and terminates in a nozzle directed downward into the cylindrical smoke stack mentioned; and when the engines are running there is a very perceptible down-draught through the rectangular hole at the rear of the smoke bonnet.

The Legislation Committee of the Trades and Labor Council, Toronto, waited on Hon. John Dryden recently, to ask that certain clauses in the Ontario Factories Act be rigorously enforced. They want a blower attached to all dry emery wheels

EXCESSIVE HEATING IN A CORLISS ENGINE.

Editor CANADIAN ENGINEER :

What is the correct lead to give valves of a cross compound Corliss engine, driving air compressors direct connected to the piston rods ? What would be the pressure on crank pins when thus connected, and would this pressure on crank pins be sufficient to cause excessive heating ?

Toronto, October 15th, 1899. ENGINEER.

THE DIESEL HEAT MOTOR.*

The Diesel motor has attracted more or less attention for the last two years, but the principles upon which it operates, and which are so widely different from other motors, have not been generally understood. Hirn's work at Mulhouse, Professor Lanza's work in Boston, and Isherwood's practical experiments, roused mechanical engineers to the importance of considering the utilization and conservation of heat in the steam engine as the fundamental question of design. Even Ericsson, one of the pioneers of the steam engine, had previously turned to the hot-air engine to escape from those losses inseparable from the employment of steam. Naturally enough, then, many scientists and inventors turned again to the internal combustion engine, which had been previously experimentally developed by Barnett in England, Drake in America, LeNoir in France, improved by Brayton, Barsanti, and others, ably discussed and advocated by Dr. Siemens, and finally developed into a practical working machine by Otto in 1876. Otto's master patent, though at first vehemently attacked, became the foundation on which Priestman, Crossley, Atkinson, Capitaine, Clerk, and others, built up a number of types with a gradual and satisfactory increase in economy. But they all worked in the beaten path of mixing a charge of gas and air, carefully compressing it, and igniting it for explosive action by various igniting devices. Not one attempted a vital change in the cycle itself until Rudolph Diesel, in 1893, proclaimed his method and attempted the development of a practical working engine on the ideal of Carnot.

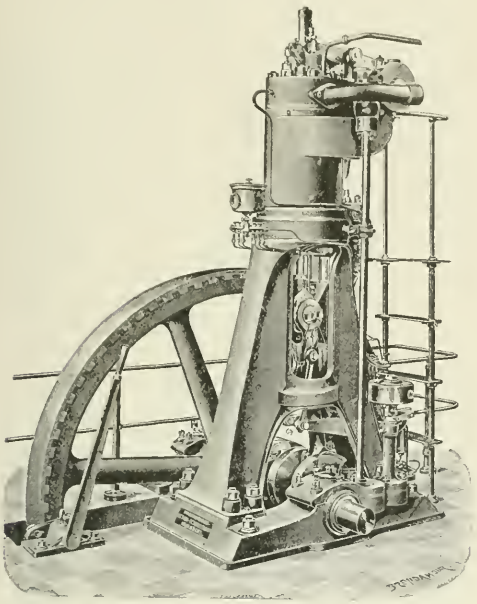
After experimenting with various vapors more permanent than steam, and at first attempting both to add and withdraw the heat from the working fluid from without, he reached the conclusion that the atmosphere about us would furnish a cheap, endless supply of permanent gas, available not only as the vehicle of heat, but as the means of evolving it from the fuel employed.

Rudolph Diesel is a Bavarian, 40 years old. He received his early education in Paris, where his parents then resided, until they were forced to emigrate in 1870 by the decree of the empire. He is a man of studious habits, a good mathematician and thoroughly versed in the science of thermo-dynamics, which he has made his life study. As a student at Munich he was a pupil of the celebrated Professor Linde, now well known as the inventor and builder of the ice machine which bears his name. Since the publication of his lecture of June 16, 1897, he has been fairly overwhelmed with praise and congratulations by the leading professionals of Europe. For the past fifteen years Mr. Diesel has devoted himself almost entirely to this work. He even built a small experimental motor in Paris many years ago, the working of which enabled him to modify his first theories considerably. He, however, took the precaution to have the parts of this motor made in different shops to prevent his ideas and processes from becoming known. In 1892 he made his applications for his first patents in different countries. On the 16th of June, 1897, he delivered a lecture before the National Society of German Engineers at Cassel, in which he not only developed his theories, but exhibited in drawings the actual construction of his motor, and gave some data in regard to the practical results obtained at Augsburg. Professor M. Schroeter followed Diesel in further development of the theory of the motor, and gave in detail the results of tests made by him on the first experimental motor, and stated his conviction that the motor was now ready for commercial work.

Diesel's idea was to follow Carnot's cycle strictly, obtaining the lower isothermal and adiabatic curves by compression, and the upper lines by combustion and expansion. For a long time he experimented with various vapors, which, under normal con-

*Extracts from a paper read before the Massachusetts Institute of Technology by E. D. Meier, C.E., M.E.

ditions, are far above their points of condensation. Ammonia vapors, especially, seem to have the properties best suited to the theoretical process. But great difficulties in handling them were encountered in practice. In the endeavor to replace them he was naturally lead to experiment with air. Up to this time he had necessarily applied his heat from without, and was subjected to the losses and limitations due to the metal walls



20 H. P. Diesel Motor—German Type.

through which it had to pass. He was then subject to the same losses which had defeated Ericsson, and was compelled to make the step which made his motor an internal combustion engine. Starting out, then, with the intention of improving the caloric process of the steam engine, he reached, in a round-about way, means similar to those employed in gas and oil engines. But this similarity is strictly limited to the fact of internal combustion, the method of combustion being radically different. Further, finding that to begin his compression isothermally led him into pressure which must, in our present practice, be considered excessive, he abandoned that part of the Carnot cycle, and made his compression adiabatic throughout, thus reducing the necessary pressures from over 100 atmospheres to between 30 and 40. When, as in the history of the steam engine, these higher pressures become practically feasible, a return to the original complete process may become advisable. Diesel's fundamental invention is then really a process of converting heat into work; this of course has been supplemented by other inventions naturally growing out of the persistent and logical development of a practical machine to operate on this process. It was Diesel's first intention to build a motor with three cylinders, embodying compound compression and compound expansion, and one of this type has been built at Augsburg, and is to be thoroughly tested on producer gas. But the development of the single cylinder type has been so satisfactory, and the demand for them has become so great, that at present the German shops are busy to their fullest extent, building their simpler form. As this form has reached an absolute efficiency of 30 per cent., and is in every way a simple and practical machine, there is at present no reason for developing the compound motor. The cut here given represents the first of these 20 h.p. motors, built by the Nuremberg Machine Works. This motor was exhibited at the Electrical Exposition in New York city, held in May, 1898. In appearance it resembles a vertical marine engine. A strong base plate supports the main journals of the crank shaft, outboard bearings being provided for the shaft extensions which carry the fly-wheel and pulley. Bolted to the base plate is a stout A. frame, containing the guides. In the rear leg of this frame a small air pump is supported. On the top of the frame is placed a cylinder open at the bottom. Its top is closed by a head cast in one piece, in which are contained one suction valve for air, one discharge valve for spent gases, and a needle valve for the fuel. The admission to the casing of this fuel valve is controlled by a stop valve, which can be instantly closed to shut off the supply of fuel. Besides this, there is a starting valve used only in starting the engine. Cylinder and air pumps are water jacketed. This water jacket was not used in the earlier experimental engines, but is found advantageous in keeping the temperature of the working parts uniform. As the temperature of combustion is so much lower than that of the explosion type of engines, a much smaller amount of water suffices for this. In the earlier German engines the main shaft and crank are bored for water cooling. This, however, grew out of the practice of Krupp's Steel Works of boring all small shafts produced. The practice has been discarded in England and in America as unnecessary. The air pump is driven by a set of levers attached to the main cross-head. Conveniently placed to one side is an air vessel known as the starting tank, connected by copper pipe to the air pump, and to the fuel valve casing.

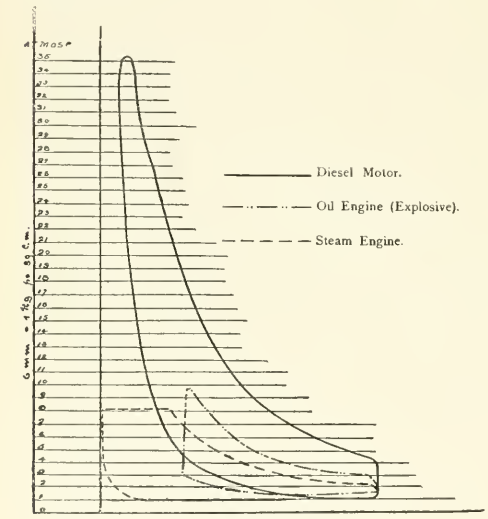
The operation is as follows: On one down stroke the main cylinder is completely filled with pure air; the next up stroke compresses this to about 35 atmospheres, creating a temperature more than sufficient to ignite the fuel. At the beginning of the next down stroke the fuel valve opens, and the petroleum atomized by passing through a spool of fine netting (wire), is injected during a predetermined part of the stroke into this red-hot air, resulting in combustion controlled as to pressure and temperature. This injection is made possible by the air in the starting tank, which is kept by the small air pump at a pressure some 5 to 10 atmospheres greater than that in the main cylinder. A small quantity of the air enters with the fuel charge, which it atomizes as described. When the motor is running at full load a very small quantity of injected air suffices, and the pressure in the air tank steadily rises. At half-load, with less fuel injected, more air passes in. For this reason, the starting tank is made large enough to equalize these differences, and a small safety valve is provided on the air pump. The petroleum is pumped into the fuel valve casing by a small oil pump, bolted to the base plate. This pump is arranged to pump a fixed maximum quantity of petroleum. A by-pass is provided so that this whole quantity, or any portion of it, can be returned to the supply tank. The governor controls the action of this by-pass valve, closing it just long enough to compel the exact quantity of the fuel required to pass into the fuel valve casing. As this requires only the movement of a small light wedge, the regulation is accomplished with great exactness. In this regulation resides a great advantage for the Diesel motor. The full charge of air being always supplied for complete combustion, it matters not whether the governor permits one or fifty drops of petroleum to enter the working cylinder at each motor stroke; the combustion is always complete. Thus variations in excess of air over that theoretically necessary, from 26 to 116 per cent., have been measured, and the analysis of the spent gases shows no trace of unburnt carbon or hydrogen. It is hard to conceive a more perfect combustion than that which takes place when fuel is sprayed, finely powdered or atomized into red-hot air, just beginning to expand. To stop the motor it is only necessary to close the valve which admits the petroleum into the fuel valve casing. The valve gear consists of a series of cams placed on a shaft and journaled on brackets cast on the cylinder.

In starting the motor a hand lever is pulled to one side, throwing all these cams, except the exhaust valve cam, out of gear, and throwing a special cam into gear with the starting valve. A few strokes of the petroleum pump by a hand lever inject a small quantity of petroleum into the fuel valve casing. The fly-wheel is thrown over by a lever a trifle beyond the upper dead point. The fuel throttle valve is opened, and by a turn of the hand wheel communication is established between the air tank and the starting valve. A single charge of highly compressed cold air enters the cylinder, sufficient to give two revolutions of the fly-wheel at moderate speed. At the close of the first revolution the starting valve cam is automatically thrown out of, and the other cams into, gear, and thus on the second revolution a full charge of air is drawn in and compressed, and in less than thirty seconds the motor is running at full speed.

Mr. Diesel makes a sharp distinction between the tempera-

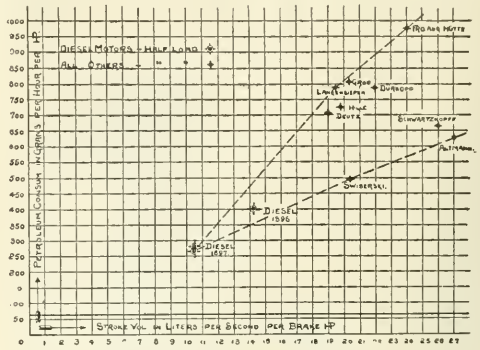
ture of ignition and the temperature of combustion; the first is a constant value at each pressure, and dependent only on the physical qualities of the fuel, the higher the pressure the lower the temperature of ignition. The temperature of combustion on the other hand is variable, depends on many conditions, and especially on the quality of the air by which the combustion is maintained, but it is always higher than the temperature of ignition. Diesel's radical departure from all previous practice is in generating a combustion temperature by mechanical compression of pure air, utilizing this temperature to ignite the fuel, and by so introducing the fuel that the heat lost by expansion is practically balanced by the heat added by combustion.

Before the completion of this perfect engine, certain critics of Diesel's theories contended that the dimensions of the cylinder, and all other working parts would become so great as to make it impracticable to build such engines. But in Diesel's engines the increase and the decrease in pressures are so gradual that there is no shock. The change from one to the other is always accomplished at a dead point. In all motors relying on explosion for their moving force, and even in the steam engine, there is a direct blow at the moment of ignition or admission. I present here a drawing on which indicator diagrams of a high pressure steam engine, of an explosion type motor, and of a Diesel motor have been drawn, based on the same piston displacement.

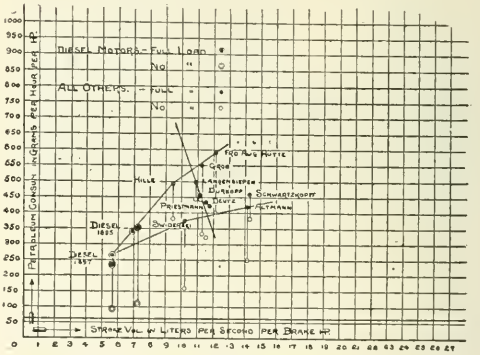


Comparative Diagrams—Diesel Motor Oil Engine and Steam Engine.

Diesel's and the explosion motor diagrams can be directly compared, since both work on the four-stroke cycle. The steam engine diagram should be quadrupled. This disposes of the objections just referred to. These second and third diagrams are graphic comparisons of the Diesel motor, with a number of the best petroleum motors as to economy in fuel and volume swept by the piston per second. They are given on the authority of Professor Hartmann, well known as a careful and conscientious observer in this field. The abscissae represent piston displacement in liters per second, the ordinates petroleum consumption in grams per hour, both figured on the effective or B.H.P. The full lines embrace the results for full loads, the dotted lines those for half loads. The comparison is between engines which burn ordinary safe lamp petroleum and kerosene; results obtained on benzine or naphtha are not considered, since motors depending on such dangerous fuels can never be generally adopted for industrial purposes. The calorific value of these highly inflammable and explosive liquids is no greater than that of safe kerosene or of fuel oil. You will notice that we find the Diesel results in both cases near the apex of the angle; or plainly put, both at rated capacity and at half load the Diesel motor shows the smallest cylinder dimensions and the least expenditure of fuel. Remember that the others represent the best results from engines carefully developed and improved in all mechanical details, while the Diesel motor is but the third one ever built, and that in its construction the practical realization of the theoretical cycle was the primal consideration, mechanical improvement being left for the future commercial exploitation of the machine. Broadly speaking, the absolute



Comparative Chart—Fuel Consumption and Stroke Volume, Half Load.



Comparative Chart—Fuel Consumption and Stroke Volume, Full Load.

efficiencies of the best known heat engines of to-day range about as follows, taking into account actual calorific values of the fuel and effective or brake horse-power:

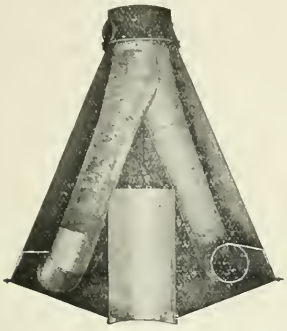
	Per cent.
Small auxiliary steam engines, pumps, etc.	6 to 10
Plain slide valve engines in good condition	3 to 5
Single cylinder Corliss engines	6
Compound condensing engines	8
Reheating compound or triple expansion steam engines	12
Best oil engines (explosion type)	16
Best gas engines (explosion type)	19
Diesel motor	28 to 30

All these are compared when running steadily at full load or rating at point of best economy. But in a large majority of the applications of all these prime movers, the exigencies of the service require them to be run frequently at three-quarters and half load for a large part of their daily service. It is conceded that in most engines the internal frictions or mechanical losses are a fixed amount, so that a loss of 15 per cent. at full load becomes 30 per cent. at half load. And thermal losses increase even more rapidly, for instance, in steam engines by cylinder condensation. In gas and oil engines the absolute efficiencies have in some cases shown a measured loss of nearly 60 per cent. In the Diesel motor the thermal efficiency is shown to increase with decreasing loads, thus counteracting in a marked degree the loss in mechanical efficiency which it shares with other machines. From a number of carefully checked tests I found the average drop in absolute efficiency from full to half load to be only 15 to 16 per cent. in the Diesel motor. So promptly and easily does it respond to a change of load that a sudden addition of 80 per cent. to the electrical load on the

Diesel motor at the Electrical Exposition at New York, by the throw of a switch, was not noticed by observers of the engines or the lights, though promptly registered by the ammeter. For variable load, then, the Diesel motor will show in practice a much greater superiority over all rivals than that apparent from the tabular figures just given.

A NEW FORM OF EXHAUST HEAD.

One of the important features of a modern steam plant is an exhaust steam pipe head. To be effective it must thoroughly separate the water from the steam, and thereby prevent the constant spraying of roofs and walls with consequent deterioration and expensive repairs. In the form of exhaust head built by the B. F. Sturtevant Co., Boston, Mass., and illustrated herewith, the principle of centrifugal force is utilized to secure perfect separation. Dry exhaust steam weighs only .038 lbs. per cubic foot, while water of the same temperature weighs 59.36



pounds per cubic foot. It is therefore evident that inasmuch as centrifugal force is proportional to the weights of the bodies in motion, the water will be thrown outward with $\frac{59.36}{.038}$, equals 1,562 times the force exerted upon the steam. In the Sturtevant exhaust head the steam passes up the interior pipes, is discharged tangentially close to the shell, and is thereby given a vigorous whirling motion. The entrained water—likewise the oil—flies outward, strikes the cool side and trickles down to the outlet at the bottom. The steam now perfectly dry, finds ready escape through the central opening above. The action is claimed to be so positive and absolute that perfect separation must be the result. These heads are built in sizes to fit pipes from 1 inch to 20 inches. All sizes above 10 inches are flanged instead of tapped.

THE LATE PROFESSOR BUNSEN.

Prof. Robert W. Bunsen died recently at Heidelberg, Germany. The age of the great scientist was 88, and he formed a most interesting link between the German scientific men of the past and those of to-day. As the obituary notice in the London Times says, Prof. Bunsen passed away full of years and of honors. He was born in 1810 at Gottingen, and graduated in the university of that town. The greater portion of his scientific researches were carried out at Heidelberg, where he held the chair of experimental chemistry from 1852 until his retirement in 1889. To enumerate Prof. Bunsen's discoveries in almost every branch of chemistry would fill a treatise. Suffice it here to enumerate those which have made Bunsen's name a household word. First came Bunsen voltaic battery, which, supplanting the more expensive form bearing the name of our countryman Grove, was generally used as the cheapest and most effective mode of generating electricity until the dynamo displaced all forms of chemical batteries. Next came the Bunsen gas burner, which, it is not too much to say, is now not only a necessity in the laboratory, but in every household and every manufactory where a clean flame is wanted. About his discovery of this simple and effective apparatus an interesting tale could be told. No one before Bunsen had thought it possible that a mixture of coal-gas and air could be made to burn without explosion from a simple tube burner. His clear conception of the laws which apply to the inflammation of such a mixture showed him that it was possible to arrange the dimensions in such a way that a steady, smokeless, and highly combustible mixture could be obtained, but a long series of delicate experiments was needed before the perfect burner which now bears his name resulted. Prof. Bunsen's work in spectrum analysis was most valuable, and his papers on this and on the many other subjects in experimental chemistry have been valued most highly by the world of science. They also resulted in honors from foreign scientific societies being conferred on their author, which were most richly deserved and were highly valued by their recipient.

REPORT OF THE CITY ENGINEER OF TORONTO.

The annual report of the city engineer of Toronto, Ont., C. H. Rust, for 1898, has been issued. It contains a great mass of information concerning matters dealt with by the engineer's department during the year. Statistics of the city show: Area, 17.17 square miles; 257.93 miles of streets, of which 179 are paved and 78 are unpaved; 82¼ miles of lanes; 230 miles of sewers, 430 miles of sidewalks, 255 miles of water mains, 230 miles of gas mains, 130 miles of underground electric conduit, 4,300 miles of overhead electric wire, 80 miles of steam railway track, 84½ miles of single street railway tracks, 7,000,000,000 gallons of water supplied annually. During the year there were 24.64 miles of new pavements and roadways constructed, as follows: Asphalt, 3.408 miles; brick, on concrete, 6.079; brick, on gravel, .352; brick, on concrete (track allowance), .413; cedar block and brick, on concrete, (track allowance), .280; cedar block, on concrete, .084; cedar block, on gravel, 4.831; macadam, 2.089; gravel, 4.756; concrete, .057. Reconstruction of track allowances—brick, 3.341; scoria, 2.986.

The engineer, referring to the increasing demand for improved roadways, says that the ratepayers are, owing to better times, beginning to realize the advantage of having a good pavement in front of their property. He mentions his disapproval of gravel roadways, as unsuitable for city streets, and he advocates discouragement of their construction. It is noted that a great many of the ratepayers have, Mr. Rust thinks, unjustly condemned cedar block pavements. The difficulty has been in the past that too long a time was given for the payment of the cost of cedar block pavements. Instead of ten years the time for payment is now five years. A cedar block pavement is cheap, easily laid and repaired, noiseless, and, dependent upon the extent of traffic, will remain in good repair for from six to eight years, and at the end of that period it can be renewed at a cost of from 45 to 50 cents per square yard, making it the cheapest pavement that can be laid, and much to be preferred to a gravel roadway, which costs about 10 per cent. more.

A large folder map is inserted in the report, which shows all the streets in the city, and they are colored to show the various pavements. Those which are in immediate need of repavement are also indicated.

Respecting poles, wires and conduits on streets, it is said that the time has arrived when strong efforts should be made to get rid of a number of poles and overhead wires, especially in the central portion of the city; and we should try and arrive at an agreement with the different electrical companies in the matter of the construction of underground conduits, which should be constructed by the city, and a yearly rental charged the different companies for the use of them. During the preceding year this department made several attempts to bring the companies together, so as to avoid the duplication of pole lines, but those efforts did not result in any satisfactory arrangement.

Mr. Rust urges improvements to the water works system, to place that branch of the city service absolutely beyond failure and guarantee an adequate supply of water for domestic and fire requirements for some years to come. Mr. Rust states most emphatically that a new conduit is necessary between the Island shore crib and the pumping station; at present the supply is endangered with low water. A large expenditure for mains, conduits and pumps, in order to place the water works in a satisfactory condition is recommended. He also recommends the installation of another 10,000,000 gallon high duty engine at the main pumping station, as an economical expenditure. A new 36-inch main is said to be required from the corner of Bathurst

street and College street to the reservoir, so as to provide a full supply for the high level district, and also to enable the reservoir to be filled in three or four instead of sixteen or twenty days, as at present; and also to enable a fire pressure to be maintained on the low level or main district at times when it may be necessary to shut down an engine for repairs at the main pumping station. He considers that a daily supply of from 14,000,000 to 15,000,000 gallons should be amply sufficient for all purposes If the present waste of water could be prevented, there is no doubt that a further reduction in our water rates could be made.

THE METRIC SYSTEM.*

In a paper on the Metric System, published in The London Times in 1896, Herbert Spencer in opposing its introduction begins by declaring that the "advocates of the metric system allege that all opposition to it results from ignorant prejudice," which he very properly declares is far from true. What is far more dangerous as an obstacle to human progress, and often far more common, is what may be called "intelligent prejudice," meaning thereby an obstinate conservatism which makes people cling to what is or has been, merely because it is or has been. It will be convenient to consider the objections offered by Mr. Spencer in the order in which he has presented them in the four separate letters which go to make up his article. Mr. Spencer reproduced in quotation a considerable part of the well-known argument of Sir John Herschel, written and widely published over thirty years ago, in which he claimed, first, that the metre was not exactly the ten-millionth of the terrestrial meridian passing through France, which was entirely correct, and that, therefore, it was not a good unit for international use, which does not at all follow. He further attempted to show that the polar radius of the earth, which could never be known except indirectly, was a better unit than the quadrant, a large part of which could be measured directly, and that this radius differed by only eighty-two yards from 500,500,000 English inches. He then proposed to increase the English standard by its one-thousandth part, so as to furnish what he declared would then be "a system of linear measurement the purest and most ideally perfect imaginable." It has always been a surprise that so able a mathematician and astronomer could have overlooked the inherent weakness in such an argument. The simple facts are that while in the beginning the metre was made to be as nearly as possible one ten-millionth of the meridian, no one imagined that it could be exactly so, or rather that we could ever know that it was exactly so. It is sufficiently near that value to be very convenient in calculations relating to terrestrial distances and areas, but it must always be considered as defined by a material standard, and no metrologist ever thinks of it in any other sense. Before beginning the exposition of his own views he ventures to quote another objector to the metric system in the person of Prof. H. A. Hazen, of the United States Weather Bureau, who some time ago argued that its adoption would necessarily include that of the centigrade thermometer scale, and that as, in his opinion, this was very bad, the metric system must be very bad.

Mr. Spencer objects to the metric system as, although it is a century old, it has not yet, even in France, entirely driven out some of the old denominations and units. In reply to this it may be said that little research is required to reveal innumerable examples of persistence in the use of words and things for more than a hundred years after their betters were available. The next objection is worthy of more serious consideration, and it has been given (for it has long been discussed) a good deal of weight by many thoughtful people. It refers to the alleged universal tendency to continual bisection, thus leading to the use of halves, quarters, eighths, sixteenths, thirty seconds, sixty fourths, and, sometimes in subdividing the inch, one-hundred-and twenty eighths. To begin with, the existence of any such inherent tendency is quite open to discussion, but, without going into that, it is at least plain that it has never shown itself in the evolution of systems of weights and measures. In all, as well as in the English money units and denominations, there is no indication whatever of this "natural tendency" toward continual halving. It is a common practice, possibly growing out of a tendency in some degree natural, to continually bisect a single unit. What possible objection can there be to speaking of a half or a quarter or an eighth of a mile or rod or yard or inch, if one wishes to do so? And no more can there be to a half, quarter, eighth, or sixteenth of a kilometre, kilogramme, metre, gramme, centimetre, millimetre, etc., nor, again, to the use of such fractional parts as thirds, fifths, or sevenths, if they seem to be desirable. But to compare the two systems in this respect one should undertake such a problem as finding the value of a third, quarter, fifth, or eighth of a mile or a ton in rods, yards, feet, and inches, or hundredweight, pounds, ounces, drams, and grains, and then do the same thing in the metric system. The enormous superiority of the latter will at once be revealed. On the other hand, it cannot be denied that there is, and has been for many years, a strong tendency toward the decimal subdivision of single units, even among users of our own clumsy system of weights and measures. In weight, for instance, in the United States it has been long ago decided that a hundredweight shall be a hundred pounds, as its name implies, and not a hundred and twelve as in England, and our ton is almost universally two thousand pounds, although they still retain the traditional ton of twenty-two hundred and forty pounds in certain transactions; and as if to emphasize the utter absurdity of the thing, in some parts of New England a "long" or "gross" ton of coal weighs twenty-two hundred pounds. In many extensive calculations the avoirdupois pound is adopted as the only unit of weight, and fractional parts are expressed in tenths, hundredths, etc.; and this is found to reduce the labor of such calculations enormously. In length measure the tendency toward decimalization is still more marked. In land surveying and in engineering operations it is now the all but universal practice to use the foot as the unit and multiply and divide decimally.

In accurate machine-shop practice the use of decimal divisions is becoming almost universal. The unit is generally the inch, and it is subdivided into tenths, hundredths, thousandths, etc. "True to one hundredth, or one thousandth, or one ten-thousandth of an inch" is heard a hundred times oftener in every shop than "correct within a sixty-fourth or a hundred and twenty-eighth," etc., and it means not only greater convenience of expression and measurement, but an actually higher standard in precision of workmanship. To the objection, then, that the tendency of mankind is toward a binary rather than a decimal division of units, which is almost the only one offered by Mr. Spencer worthy of serious consideration, we may briefly reply by saying that even granting it to be a fact, it has no bearing whatever on the questions of ratios and relations of units, which is what distinguishes one system from another; that such a tendency may find expression in one system as well as another, and certainly with infinitely greater facility in the metric system than that now in use among English-speaking people; and, furthermore, that the estimation of fractional parts by tenths or hundredths is believed by many who habitually work that way to be both easier and more accurate than by halves, quarters, eighths, etc., and as a matter of fact the prevailing tendency is away from the latter and toward the former.

Mr. Spencer resorts to quotation, and brief reference should be made to the arguments set up by some of his authorities. The letter of Sir Frederick Bramwell contains some remarkable statements. His assertion that the new system will require "more figures to perform ordinary sums than on our present system, when rightly applied," is so grossly incorrect, as may be easily proved by a few examples, that no time need be spent in controverting it. The same might be said of his further assertion that it is more likely to lead to error, and, above all, to the common error in placing the decimal point. This last statement is frequently made, and it is worth while, therefore, to call attention to the fact that in all ordinary business transactions in which the decimal system is used, and in all calculations for that matter, the error of a misplaced decimal point is one of the rarest of all errors. This is because of the generally quick and certain detection of such a mistake. To misplace the decimal point by the smallest possible amount is to change the result tenfold, and usually so great an error is instantly detected by means of approximate knowledge or other checks. Take the United States' own money system, for example: it is perfectly safe to say that other mistakes are a million times more frequent than a persistent, undetected misplacing of the decimal point. Yet, curiously enough, considerable weight has been given to this

*Extracts from a paper by Prof. T. C. Mendenhall, President Worcester Polytechnic Institute, in Appleton's Popular Science Monthly.

objection to the metric system of weights and measures, which is, on the contrary, vastly less liable to errors of computation than that now in use. Sir Frederick also furnishes an extensive extract, giving the views of the first Napoleon on the subject of reform in weights and measures. Many of the stock arguments are repeated, and if they had not been thrashed over long ago it would be perfectly easy to take them up one by one and show their absurdity. An entire lack of any really accurate knowledge of the subject and an absence of any sort of conception of the simplest metrological principles are shown in a single quotation: "A toise, a foot, an inch, a line, a point, are fixed portions of extensions, which the imagination conceives independent of their relations one to another; if, then, we ask for the third of an inch, the mind goes into instant operation. The length called an inch is divided into three parts. By the new system, on the contrary, the mind has not to divide an inch into thirds, but a metre into a hundred and eleven parts." It is difficult to properly characterize such utter nonsense; but, fortunately, the French people, who are to-day the leaders in the world's metrology, were not obliged to take their science, as they were most other things, from the first consul. A group of the most distinguished Frenchmen of any period had perfected this system, even in the very midst of the bloody revolution which closed the last century, and when their final report was made in an address to the legislative chambers by the celebrated La Place, the event was described by Adams as a "spectacle at once so rare and so sublime . . . that not to pause for a moment, were it even from occupations not essentially connected with it, to enjoy the contemplation of a scene so honorable to the character and capacities of our species, would argue a want of sensibility to appreciate its worth. This scene formed an epoch in the history of man. It was an example and an admonition to the legislators of every nation and of all after times."

Mr. Spencer also quotes from an auditor who had to go over £20,000 of accounts, and who was "very thankful that it was not in francs." At first blush it seems entirely natural and creditable to him as an Englishman to rejoice that his twenty thousand is in pounds sterling rather than francs; but, after all, his remark is only a reflection of that not uncommon English sentiment that the imperial monetary system is more perfect than any other in the wide world. This sentiment is doubtless the outgrowth of national pride and intellectual inactivity; it is not entertained by the majority of the more thoughtful and scholarly Englishmen, and, furthermore, it is in every respect false. It is unnecessary to consume time in quoting the opinion of England's most distinguished scholars, to show this.

I must be content to stop without reference to a few other points raised by Mr. Spencer, for they are essentially all of a kind. There is a sentiment underlying much of his argument, to which I must briefly refer, however, because it has shown itself in other recent discussions of this subject. I refer to an anxiety lest the "poor man" be in some way injured by the proposed reform. It has come to be the fashion in all political or economical controversies to exhibit a consuming interest in the poor man's welfare; indeed one marvels that there should continue to be any poor, so universal and so intense appears to be this anxiety to shield them from all harm. Fortunately, the so-called "poor man" is not so blind to his own interests as some would have it appear, and he is quite alive to the fact that the proposed metrological reform is fully as important to him as to anybody.

Finally, it ought to be understood that the advocates of the metric system do not assume that it can come into use immediately or without considerable hardship. It took nearly a century to fairly establish the decimal money system in the United States, which no one would now think of giving up. During all this time old units and denominations continued to be used in a lessening degree, although not authorized by law. Something of the kind must occur in the transfer from our illogical, brain destroying, time-consuming system of weights and measures for the more perfect system for which it is sure to make way. Furthermore, they heartily welcome and desire the presentation of all arguments against or objections to the metric system, believing that the more widely it is known and discussed the more supporters it will have. They expect to meet occasionally such "intelligent prejudice" as is exhibited by Mr. Herbert Spencer, whose contribution to the discussion of the subject is sure to be considered in the years to come as altogether the most remarkable to be found in any time or tongue.

THE PRACTICAL MAN.

Weights of square and round bars of wrought iron in pounds per lineal foot.—Kent.

Iron weighing 480 lbs. per cubic foot. For steel add 2 per cent.

To compute the weight of sheet steel—Divide the thickness, expressed in thousandths by 25; the result is the weight, in pounds, per square foot.

For weight of sheet brass, add 11 per cent.

For weight of sheet copper, add 10 per cent.

THE WATER CURTAIN.

For many years the water curtain has been in use in Canada as a means for fire protection. Some years ago when a building next door to the T. Eaton Co., Toronto, was burned down the value of this device was most apparent, since unshuttered windows within a few feet of the flames were not even cracked by the intense heat, because of the sheet of water which fell from the roof and from the tops of the windows where perforated pipes had been arranged for the purpose. That this is looked upon as a great novelty is evidenced from the following paragraph, quoted from a recent issue of The Engineering News, New York:

"Another form of protection against exposure fires which has recently been employed is the outside fire sprinkler system. This has been applied on an elaborate scale to the costly new public library building for the city of Chicago. As many of our readers doubtless recall, water curtains have been frequently suggested as a means of fire protection, but this is, we believe, the first instance, in America at least, in which such a device has actually been constructed."

GREEN'S ECONOMIZER.

Editor CANADIAN ENGINEER:

Referring to the article in your June issue, entitled "A Dismissed Engineer," it would appear that the utility of the economizer was not what it was guaranteed to be to the city of Toronto. The question of the utility of the economizer to the city of Toronto, and of the sufficiency of the tests made, is to be thoroughly sifted in an action brought by us, and now pending, and we are fully prepared to show when the proper time comes that the economizer has done everything that it was warranted to do. We consider it a little unfair on the part of your paper in the meantime to publish extracts from Judge MacDougall's report, which is based upon an investigation entirely ex parte as far as our company is concerned.

THE GREEN FUEL ECONOMIZER CO.

Matteawan, N.Y., August 15th, 1899.

NEW CATALOGUES.

Cranes—The Northern Engineering Works, of Detroit, Mich., U.S.A., have sent out their first catalogue, consisting of twenty pages, which illustrate three motor electric travelling cranes, compressed air travelling cranes, portable pendant winch, hand chains, jib cranes of the cantilever and single braced types, air hoists. Tumblers of different styles suitable for foundry use are also shown. It is sent free to enquirers. G. A. True is general manager; the engineer is Ed. S. Reid, late of the Whiting Foundry Equipment Co., Chicago.

The Gutta Percha Co.'s pocket catalogue for 1899-1900 to hand, and it illustrates the various styles of rubber footwear made by this well-known concern, under their famous trade mark, "Maltese Cross." Almost every conceivable style of footwear is shown from children's rubbers to lumbermen's, sporting and firemen's gum boots.

SEPTIC TANK SYSTEM OF SEWAGE TREATMENT.

A great deal of interest is being taken in Ontario in the Septic tank system of sewage treatment. C. H. Rust, C.E., city engineer of Toronto, has recommended the Septic tank system for adoption in that city. The following description of two plants on this system now in operation in the United States is taken from a recent issue of The Engineering News, New York:

The largest Septic tank for the treatment of sewage thus far built in the United States is located at Verona, N.J., seven or eight miles from Newark. It receives the sewage of a branch of the Essex County Lunatic Asylum, and was designed and built by Jas. Owen, M. Am. Soc. C.E. The tank and supplementary filter beds were put in operation about November, 1898, and now receive the sewage from a large building containing some 300 patients and attendants. Quite a large roof area is connected with the sewerage system, the connection having been made before it was decided to treat the sewage. The amount of sewage treated daily is placed by Mr. Owen at 40,000 gallons. The tank is of concrete, and is 18 x 50 ft. by 10 ft. deep, giving a capacity of about 65,000 gallons. It has a trapped inlet, from a small grit chamber 4 feet square. There is a man-hole at about the center of the top of the concrete roof of the tank, but the cover of this is sealed up with cement. The tank effluent passes out through a 16-inch pipe, beneath the surface on to four filter beds. Each bed is 14 feet square, with concrete walls and bottom. At the intersection of the division walls of the bed is a sheet iron distributing pan, 3 to 4 feet in diameter, with a bottom curved upwards, and a notch in one side to allow the sewage to flow on to the bed. The pan was provided with a device designed to cause it to revolve automatically through one-fourth of its circumference whenever the bed receiving sewage became filled, but the device has not proved successful, and the pan is now revolved by hand. The filtering material was originally composed of sand at the top, then coke, then gravel, resting on a layer of large-sized stone, making a total depth of about 5 feet. This choked up in about three months' of operation, which was in winter weather, making it difficult to do any cleaning. All the material, except the large stone, has been replaced by 3½ feet of coke, with 6 inches of coarse sand at the top. The walls of the bed extend about 16 inches above the top of the sand. The tank has not been cleaned since it was put in use. The amount of sludge which has accumulated is unknown, as the tank is sealed. To the eye the tank effluent, as it flows over the distributing pan, has a cloudy or slightly milky appearance, but it seems to be pretty free from suspended matters. On the bed, however, a depth of 0 to 12 inches has a brownish or yellowish look, like water standing in a muddy pool. A silver coin, held between the thumb and finger, could scarcely be distinguished at a depth of 5 or 6 inches. The tank effluent flowing from the pipe or dipped up in the hand from over the bed, had a strong sewage smell. One of the filter beds, which was in need of being raked, showed a thin skin of dark, almost black, sludge, which had curled up in small patches, on partially drying out. This, too, had a strong sewage smell. The effluent from the filter beds is discharged into a ditch leading into a small stream. This effluent at a point where it issued from the beds also had a pretty strong odor, less decided than that directly from the tank. As the four beds have a combined area of only 784 square feet, they work at an average rate of more than 2,000,000 gallons per acre, per day, assuming a total daily flow of 40,000 gallons. This is very high. With the present relation between daily flow and tank capacity the sewage remains in the tank about 40 hours, assuming proper distribution through the tank, and making no allowance for sludge accumulation. Perhaps a shorter stay in the tank or a more thorough aeration, or both, would enable the filter beds to do better work. As it is now, there is reason to believe that the sewage reaches the beds in such a state that little or no nitrification could be expected, except at a very low rate of filtration. It is realized that the beds are overworked, and a supplementary filtering area is proposed. The present plant cost about $2,600.

In March, 1898, after careful study into the more recent English method of bacterial purification of sewage had been made for the city of Columbus, Ohio, and their trial then recommended, beginning on a small scale, an opportunity was afforded Alvard & Shields, engineers, Chicago, to install a plant of this character for a large Golf and Polo Club house near Chicago. The soil of this vicinity being a very heavy clay, was not adapted to intermittent subsoil irrigation, which had already been ineffectually tried, and the expense of procuring sand, which had to be hauled from a great distance, debarred the consideration of artificial sand filters to any considerable extent. No dilution was afforded for the effluent, as the stream which passed through the grounds became entirely dry during the entire season when sewage purification would be needed. The only available location was necessarily within full view of the club house, and within 100 feet of a teeing ground; so that it was important that the method adopted should be such as to enable the plant to be concealed from view.

Under these circumstances, nitrification on prepared coke beds was decided upon, and a first installation based upon a sewage flow of 2,000 gallons per day was installed in a little more than two weeks. The plant consisted of a large flushing tank, with a capacity of 850 gallons, into which the sewage from the main building discharged; a basket screen of wire of 1 inch mesh removing the large matters such as waste paper, rags,

lemon and orange peel and the like. After leaving this tank, the sewage, somewhat staled, was discharged periodically upon a single nitrification bed, in a brick chamber 12 feet in diameter, and 3 feet in depth, filled with coke, the particles of which were of chestnut size and smaller. Perforated drains led from beneath this bed to an automatically-controlled valve in a man-hole outside of the chamber, so arranged and operated by means of differentiated inlets and a float as to discharge the contents of the bed after it had remained in contact with the coke some 2½ hours. The effluent from the coke bed thence passed on to an artificial sand filter, 30 inches deep, carefully prepared of graded and suitable materials and well underdrained, and proportioned for a rate of flow of 250,000 gallons per acre per day. The object of this room arrangement was, that such an anaerobic action as might be possible would be set at work in the flush tank, which was made large for this reason; and that the partially broken-down organic matter would be the more readily acted upon in the nitrification bed. Subsequent experience led us to highly value this feature of the design and extend it. The sand filter was only added as a precautionary measure. The sewage from the very first was of high concentration owing to the insufficiency of the water supply—rough determinations showing free ammonia, 3.40 parts per 100,000; albumoid ammonia, 0.75; chlorine, 8.00. Notwithstanding this, bacterial activity was rapidly set up in the nitrification bed, and in two weeks was at its best, the effluent being bright and odorless, the sand filters evidently having little if any work to do. This condition was maintained all during the early part of the season. Among the minor practical difficulties which developed was the fact that the sewage would form a membrane over the top of the coke bed. No attention whatever was given to the plant by the attendant of the club, and if neglected for many weeks, this membrane would become water-tight. When this film was broken open the sewage would rush down violently into the coke bed, showing that it was filled with air beneath. So long as the sewage could be got to go down into the coke, it would purify itself readily; and during the entire summer no deposit was to be found at the bottom of the bed—a difficulty which had been feared at the outset. During the summer the particles of coke each became covered over with a thin film of nitrogenous matter, slightly reducing the liquid capacity of the bed; but evidently increasing bacterial activity. It is estimated that with the average flow of sewage for the summer, not less than 440 cubic yards of sludge of 90 per cent. moisture were entirely consumed in this little space of 340 cubic feet. The purification effected in the early work of the plant was over 95 per cent. of organic matter removed.

In the early part of September when some 4,000 gallons of very concentrated sewage were being purified daily, the bacterial efficiency of both coke and sand bed failed; and the results which followed brought into more prominent light its recent excellent efficiency. Where golfers had frequently passed over it and by it in scores every day without observing its proximity it became so odorous as to make its presence known for several hundred feet around. Steps were promptly taken to temporarily divert the sewage, and the filter was given a rest for about a week. The area of the secondary sand filter was slightly increased, and a new form of filling and emptying device for the coke bed was introduced; the original one having proved unreliable through corrosion. Otherwise no change was made in the plant, the coke not even being removed from its bed. At the end of the week it was in good condition, and sewage was again introduced in gradually increasing quantities. It was noticeable that the coke freed itself from impurities much more rapidly than the sand filter. The results of the season's experience having met the most sanguine expectations of the builders it was determined to increase the capacity of the plant, both to reduce the rate of flow and to meet new demands upon it from an additional building erected in the spring of this year. Accordingly it was remodelled entirely and enlarged so as to be fully capable of purifying 6,000 gallons per day. The new plant consisted of a septic tank capable of holding the maximum flow of 24 hours, built of brick, arched and sodded over. The original flush tank was dispensed with, and the sewage passed direct to the septic tank without intervening screen or grit chamber. The effluent from the septic tank passed to two square nitrification beds by means of an alternating device which has now worked successfully for six months. The nitrification beds were of brick, 12 feet square with an effective depth of three feet. One was filled with the coke used the previous year, which was found when removed from its old bed to be as clean and bright as when it had been deposited there the year before. The other bed was filled with fine cinder about pea size. The rate of flow through the nitrification beds was (intermittently) 500,000 gallons per acre per day, or about 2 cubic feet of coke to 1 cubic foot of sewage per day. The alternating device is so regulated that the beds fill in from five to six hours when running at the maximum rate. The beds have seemed to become effective after a film of nitrogenous matter forms upon the particles of coke. The effluent automatically and alternately discharged on to the sand bed used last year, which, however was not enlarged at the time the plant was remodelled. The new design seemed to be fully equal to the occasion, and most effective purification resulted even without the use of the sand bed.

A rather curious and singular disaster, however, befell it, which caused much trouble and no little study for the time being. After having operated many weeks in a most satisfactory manner it suddenly began to fall. The most noticable failure occurred in the effluent from the septic tank, which became opalescent, and the sewage in the nitrification beds rapidly filled with a large amount of black sooty filaments, denoting decomposition. It was evident that something was wrong, but for the moment just what could not be determined. A little later there began to appear on the surface of the nitrification beds a lime sludge, which ran over from the septic tanks. Investigation showed that this was nothing less than the calcium carbide ash from a large acetylene gas plant which has recently been installed, and which used 100 lbs. of carbide daily, the saturated residue of which had been daily deposited in the main sewer. It was the most convenient way for the attendant of the acetylene plant to get rid of his own troubles, but it made several weeks of exceeding trouble for others. The ash from the calcium carbide in such quantities has enough lime to completely destroy bacterial activity in the septic tank or nitrification bed, to say nothing of its being a material which is most disastrous to sewers themselves by choking and filling them with its deposit.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.

Annual Dinner of Toronto No. 1.

The 13th annual dinner of Toronto No. 1 branch of the above association was held at Webb's restaurant on Thanksgiving eve, and was the most successful reunion yet held. The tables in the main hall were filled and an "overflow" table in the adjoining room well taken up, about 150 guests being present. The dinner was served in Harry Webb's best style, and was much enjoyed by all.

The chair was occupied by the president, Herbert Terry, and on his right sat Mayor Shaw, Ald. Hallam and Ald. R. C. Pettigrew of Hamilton, representing the Hamilton branch of the C.A.S.E. On the chairman's left sat A. M. Wickens and Ald. Frame. After welcoming the guests and mentioning the fact that of all the members of this association in Toronto only two were without full employment at the present time, the toast of the "Queen" was proposed and received with enthusiasm. John Alexander sang "Stand by the Old Flag," which was loudly cheered. The toast of "Canada Our Home" was coupled with the name of Ald. Hallam, who was warmly received. In responding he said that as an adopted son of Canada he always felt it impossible to do justice to the varied charms and the vast resources of this immense country, and he could only say that he loved it. There was no man who came to this Dominion willing to work that could not make a living and save something over. Thousands who came here poor are now wealthy. A country larger than the United States and only 300,000 square miles less than the whole of Europe had great possibilities. It was a land celebrated alike for its liberty and its loyalty to the Old Land (cheers), and he was glad that in the present South African crisis Canadians were ready to stand for the integrity of the Empire. We all revolted at the conduct of the Turks to the Armenians, but the conduct of the Boers towards the Uitlanders in the Transvaal was of the same tyrannical nature. The Boers were, in fact, the Turks of South Africa. He was glad to tell them that the city council had declared a half holiday on the occasion of the departure of the South African contingent, and

he hoped they would all turn out with flags. Referring to personal matters he felt justified in speaking of his long services in the city council, and to what he had done for the public library, and it was no secret that he would be a candidate for the mayor's chair for 1900. (Voices—"We'll elect you.") He was glad to feel that he had the support of so many of those present, and he should do all in his power to promote the prosperity of the city. Geo. W. Grant and John Alexander sang the duet, "The Standard on the Braes of Mar," and were enthusiastically encored. "Toronto Our City" was coupled with the names of Mayor Shaw and Ald. Frame, who were well received, and in their remarks referred to the great advantages and bright prospects of the Queen City. Wm. Prestwick then sang a comic song and received an encore. "The Manufacturers" was replied to by G. R. Baker, of Westman & Baker, who was glad to see so bright a silver lining to the cloud that had hung over manufacturers for some years. The good times were well indicated by the price of pig iron, which had gone up from $12 a ton to $24, and was likely to go up to $30. Steel was also up in proportion, and when these materials rose it was a barometer showing expanding trade. He was glad that this association was not a labor organization, and took no part as a body in strikes and agitations, but aimed only to improve the minds of its members. This was a hopeful sign. There was no trade in which there were so many botches as in the machinists' and mechanical trades. Speaking of the need of technical education, he was surprised how few men could read a mechanical drawing, and the technical school here should have its work extended. He hoped the machinists and mechanics would take pattern by the stationary engineers in the matter of study for self improvement, for he held that every mechanic ought to have an ambition above the bench. J. D. Powers then sang "Brown October Ale," and was recalled. John Mayne was also called on and said trade in his line was remarkably good, and he did not know a boiler maker in Canada who was out of a job. Competition, however, was still keen, but he was proud to say that Canada was now competing with the greatest countries in the world in the production of machinery and other manufactures. Many members of the C.A.S.E. had become convinced of the value of the association, as some of them would not now be in the positions they occupy had it not been for the connection. The engineer was now getting to be a man of responsibility and influence, and many a manufacturer looks to him for advice on questions of coal consumption, electricity, gas, compressed air and kindred questions. Ald. Hallam here said he might remind the members that the city council had not lost sight of the technical school matter, but had already voted $75,000, but he wanted $25,000 more for the extension of the work. The site for the new school had already been secured, and as soon as this additional grant is made the work could go ahead. The matter was now in the hands of Ald. Lamb, whom the members should stir up. He (Ald. Hallam) had done all he could to promote this work, which he felt had already borne fruit, as he knew an instance where a young man who got the rudiments of his training at this school was now filling an important place in New York at a salary of $5,000. Mr. Gray then gave a trombone solo which was well rendered. A telegram was then read from City Engineer Rust regretting that absence from the city prevented his being at the dinner, but wishing them a pleasant time. The toast of "The Executive" was responded to by Robt C. Pettigrew, of Hamilton, the executive president, who said he was proud to have the honor of the presidency of this association, for he looked upon it as the greatest organization in existence. It was great because it was educational, and because its objects were solely the intellectual and technical improvement of its members. Bro. Wickens, the secretary, was preparing question papers to be sent out quarterly and this will do much to help the associations in rural districts. Alluding to the progress of his city he humorously referred to Toronto as the northern suburbs of Greater Hamilton. He closed by commending the work of the Toronto Technical School. Mr. Alexander then sang "Kings of the Road." Bro. Geo. C. Mooring, executive vice president, followed, explaining briefly the relations of the general executive to the different branches and said the Toronto branches were more flourishing than at any time in the history of the association, and its finances as well as membership were in better shape than ever. He urged the need of legislation, which would put the stationary engineer upon as good a footing as the marine engineer, and hoped something would be done at the next meeting of the Ontario Legislature. Bro. Charles Moseley, treasurer, also spoke, saying that all members interested would find in the September number of The Canadian Engineer the draft of the law which it was proposed to submit to the Legislature. There was some prejudice yet to overcome, but all could do something to remove this from the minds of members of Parliament. The association was prospering, new branches were being formed, and it was only a matter of time till our legislators would fall into line. There was now a permissive law in Ontario under which certificates of qualification were issued, but this did not fill the bill. There were numbers of second-hand steam plants in operation in this province, and there should be some sort of inspection enforced, which would prevent the use of such dangerous engines and boilers. Mr. Prestwick sang a comic song, "Old Clo'," which was encored. "The Sister Societies" was replied to by Robt. Mackie, of Hamilton branch, and Alex. McRae, of Toronto No. 2, who spoke briefly and to the point. The latter, speaking of the need of some standard of qualification for the steam engineer, mentioned a case where a boiler was taken out of an old tug, after being condemned, and sold to a man who erected it in a saw-mill. If this boiler was condemned in a tug, where it might have endangered the lives of three or four men, why should it not be condemned in a saw-mill, where it would endanger the lives of thirty or forty men? After a song by Messrs. Grant and Alexander, Bro. Pettigrew proposed "Toronto No. 1," coupling it with the names of Bros. Terry, Wickens and Huggett. The first named gentleman relegated his speech to Bro. Wickens, who expressed his strong desire to see the cause of technical education advanced more rapidly in Toronto. No business required to advance more rapidly than the engineering and mechanical trades. If a man embarking in some new line of manufacturing wanted some appliance never used before for a certain purpose it was to the mechanical man he would go to get the idea put into practice. A man who could work out practical ideas was worth something to his employer, and the more he improved the more valuable he became. There was nothing visionary in the value of technical knowledge. He saw young men before him who were living evidences of the advantages of study on practical lines, and especially of membership in this association. He believed in the idea of mutual help. There was no use in a man hiding his light under a bushel—in fact the man who did so generally had not much light to hide. As to legislation there was no reason why a stationary engineer should not be licensed. If it was necessary to license a marine engineer, who might have half a dozen lives in his care for four or five months in the year, it was surely necessary to license a stationary engineer who might have as many hundred lives in his hands the whole year round. It might be laid down as an axiom that there was no such thing as the explosion of a boiler by accident, so that skill in the handling of boilers and engines was all important. Bro. Huggett followed on the same lines, and in regard to the Technical School question claimed that the association ought to have a more direct and larger representation on the board than it was proposed to give. After the press had been responded to by representatives of The Canadian Engineer and Canadian Electrical News the gathering broke up about 1 a.m.

HAMILTON BRANCH, C.A.S.E.

A meeting of the Hamilton branch of the Canadian Association of Stationary Engineers was held October 17th, in their hall. The attendance was fairly large. The meeting marked the commencement of an educational movement in connection with the society, to extend throughout the fall and winter, and to consist of a series of papers on educational topics of particular value to the membership of the association. Among other subjects treated will be mathematics, mechanics, engineering and electricity. A paper, the first of a number on mathematics to be given by C. R. T. Fessenden, of the Westinghouse Co., dealt exhaustively with the subject of fractions. In the beginning it was emphasized that it was important that all engineers and mechanics should have a thorough knowledge of this subject, as the character of their work frequently required the use of difficult fractions. By blackboard examples he explained and illustrated the principles and use of fractions, from the elementary common fraction to problems in decimals, and gave a num-

ber of valuable rules on short methods, and the avoiding of complications in working them out. After the conclusion of the paper Mr. Fessenden satisfactorily answered and explained a number of questions on the obtaining of areas of circles, and the reduction of inches to decimals. It was announced that his next paper would probably deal with mensuration and formulas for obtaining square and cube root. On a motion by R. C. Pettigrew and George Mackie, a vote of thanks was tendered Mr. Fessenden for his paper. Mr. Pettigrew said that it was the intention of the provincial executive of the association to publish and distribute circulars containing questions on educational topics of particular interest to engineers and mechanics, and that the taking up and answering of such questions would be a prominent feature in the educational movement in connection with the local branch.

On Oct. 19th at 10.30 the C.A.S.E. and O.A.S.E. executive held a special joint meeting in the C.A.S.E. hall, Toronto. The arranging for some minor changes in the details of the clauses referring to inspectors in the draft of proposed bill (draft given in the September number of The Canadian Engineer), and also the advisability of engaging proper legal counsel to represent them before the committees who would act in harmony with the solicitor of the O.A.S.A., was discussed. It was decided to issue a circular to the subordinate associations containing a request for funds sufficient to put legislation through properly, and it was decided that the circular would also have embodied in its contents the question of a plebiscite to ascertain the wishes of the C.A.S.E. members as to whether an annual or biennial convention would be held in future. Full report of the discussion was given in our September number regarding this matter, and this is the vote decided at that time to be taken. The C.A.S.E. executive present were: President Pettigrew. Chas. Moseley, treasurer; A. C. Mooring, vice-president; John M. Dixon, Robt. Mackie, A. M. Wickens, W. Wadge and Thos. Elliott were the representatives of the O.A.S.E.

THE REED MANUFACTURING CO., ERIE, PA.

In our advertising columns our readers will find an illustration of a new malleable iron pipe vise with tool steel sectional jaws. This pipe vise is a radical departure from the old style so familiar to all plumbers and engineers, and has the maker's guarantee that one will outwear four of any solid jaw pipe vise. Another article which to engineers is of very great interest is the Economy automatic eccentric, cross-head and wrist pin oil cup for marine, traction, and stationary engines. This cup has now been on the market six years, and it is claimed that no device attached to the rotating and oscillating part of an engine can compare with the Economy in perfect lubrication and saving of oil. It is to the crank pin, the cross-head, the eccentric, and in fact to any part of the engine where there is sufficient motion to throw the oil from the bottom to the top of the cup, as the automatic sight feed lubricator is to the cylinder over the old common suction cup. Many of the large shops and factories are using these cups exclusively; the Carnegie Company having nearly five hundred in use, and the L.S. & M.S.R.R. Company have used about one thousand. Its makers state that with the old type of cup more oil is wasted during the fourteen hours the engine is idle than is used while it is running. As the Economy cup feeds only while the engine is in motion, and the oil is sprayed from the top of the cup in minute particles, it absolutely prevents any waste while the engine is idle. It is a well known fact that the least bit of good oil will keep a smooth pin cool. The trouble with all other cups is to supply sufficiently small quantity of oil to do the work and feel secure that the cup will continue to feed. With the Economy you need not set the feed, only to remove the feed cap and replace it with another of a larger or smaller feed hole as the case may require. This can be done at any time in half a minute, without the use of any tools. After the proper feed is once ascertained it will never change; the oscillating motion puts the oil into openings, and air compression completes the operation. Long-continued use does not affect its reliability. A guarantee to save 50 per cent in oil is given with each cup by the makers. The construction is claimed most perfect and simple.

The Clark pipe hanger is another noticeable product of the Reed Mnfg. Co., and is said to be the cheapest as well as the best of all pipe hangers. They are designed for use on steam water, gas and soil piping, are made of high grade malleable iron, and they are unbreakable. Piping can be hung closer to ceiling than with any other hanger it is claimed, and adjustment to any required length can be had by means of a hanger bolt, piece of pipe and coupling. It can be put up or taken down in an instant, the hanger bolt being put up first and hanger clasped over it. Hanger bolts are furnished with hanger unless otherwise ordered. The Clark adjustable beam hanger is another type also made. The Reed Manufacturing Company, Erie, Pa., will send circulars fully illustrating and describing these goods, on application.

DISCRIMINATION IN CARBON DUTIES.

Editor CANADIAN ENGINEER :

We are in receipt of your letter of the 28th, and in reply beg to state that the situation is briefly this: We have been selling our 7-16 by 12-inch carbons of second quality at approximately $5 per thousand, ½ by 12-inch at $6, f.o.b., Cleveland. The duty on our goods was formerly based on face of invoice, but since the last revision in the tariff the valuation was increased to an average price of $8 per thousand for 7-16 inch regardless of billing price, and either $8.50 or $9 for the ½-inch size. The duty was also advanced from 25 per cent. to 35 per cent., based on the new valuation. The same carbons are sold in this country at same prices as we have first mentioned, and in some cases even a little less where large quantities are ordered, but as a matter of fact, there are less of the second grade carbons used in this country than in Canada, for the reason that the American consumer has no duty to contend with, consequently his carbon cost does not run up and he can, therefore, use the first grade carbon rather than to put up with a little trouble in trying to use second grade carbons. In Canada the tendency has been to use second grade carbons in order to keep down expenses. By the time our second grade carbons are landed in Canada, the duty and freight makes them cost even more than the American consumer pays for first grade carbons. This is the reason why nearly all of the Canadian trade has been accustomed to using second grade carbons. The Canadian customs are placing a valuation on these carbons on the basis of the selling prices of first grade carbons in this country. This is where the discrimination or unjustness of the revision comes in. Yours very truly,

NATIONAL CARBON CO.

ADVANTAGES OF COKE OVER COAL AS A FUEL FOR GENERATING STEAM.*

BY ARTHUR C. FREEMAN, WALTHAM, MASS.

The item of fuel being one of the large items of expense entering into the cost of manufacturing, is necessarily one in which every manufacturer is interested. The most important fuel in use at the present time is coal. The cases where wood is used are exceptional, and becoming more so as the population increases, and timber becomes scarce and more in demand for structural purposes. It is only recently that the question of coke has been seriously considered by manufacturers here in New England, although large quantities are annually consumed in the West, where it enters into competition with both hard and soft coals. One of the reasons why this fuel has not been more extensively used in New England is possibly due to the fact that it is only recently that its manufacture has been attempted on a commercial scale. The heretofore high cost has also been one of the reasons for its no more general adoption.

Coke, as generally understood, is carbonized coal or the carbon of the coal left in the ovens after expulsion of the volatile substances by heat; or, as it is generally called, *coking*. The volatile substances are tar, pitch, gas, ammonia, and smoke producers. About one third of the weight of the coal is thrown off in the coking process; the carbon in one and one-half tons of coal is therefore largely represented by the one ton of coke. The manufacture of coke is generally carried on in heaps, retorts, or ovens, and is spoken of as gas or oven

*A paper read before the Canadian Manufacturers' Association at the annual convention in Montreal.

coke, referring, of course, to its mode of production. In the case of oven coke, the object is not so much to prepare coke as it is to obtain gas, tar and various other products. In the present day, coal is converted into coke almost exclusively in ovens constructed for this purpose, it having been found that by the use of ovens the operation is more readily conducted, and that a larger quantity and better quality are obtained.

Coke is prepared for various purposes: For increasing, or rather concentrating the quantity of carbon in the coal, and thus obtain a fuel which will yield a more intense heat than coal. For the purpose of converting coal into a fuel which does not become pasty when ignited. Coal in consequence of this property being unsuitable for blast, cupola, or other furnaces. Well burnt coke, or oven coke, is a hard, uniform, compact, solid mass, difficult to break, and not honey-combed, or very porous. Its color is black-gray or iron-gray, with a dull, metallic gloss. Good coke should contain very little sulphur. When discharged from the ovens, coke consists chiefly of columnar pieces about eight inches long and four or five inches thick, with smaller pieces mixed in. By a specially designed crusher, it is then broken up into various sizes, as egg, nut and pea. For boilers it is generally used as it comes from the ovens. The advantages claimed for this fuel are that it is clean, there being no dust, no dirt, no smoke, and but few ashes. It kindles quickly, makes the hottest fires, is easily controlled, and requires but little draft. It does not clog the boiler flues, thus obviating the frequent and expensive cleaning. This secures the complete utilization of the heat value of the fuel. It is smokeless. When looking at the stack of a boiler fired by coke, it is impossible to determine whether the boiler is running or not. This absence of smoke, especially around bleacheries and other places where expensive and fine work is carried on, and in thickly populated communities, where soot and smoke are so destructive, is a matter of no little importance.

Its general use would probably do away entirely with the smoke nuisance encountered in some of our large cities, and would add immeasurably to the comfort of those who travel by steam where coal is used. At the present time this question of smoke from soft coal is receiving the very serious consideration of the municipalities of some of our large eastern cities. New York is seriously threatened with the same affliction that has beset Pittsburg and Cincinnati, and Boston is fast losing its prestige as a clean and healthful city. Fine buildings are being injured by smoke, and what is far worse trying to the individual, the interior of houses likewise suffer from the same cause. From a hygienic standpoint the health of citizens must in a measure be impaired by breathing in this soot. With the volatile substances removed, the dangers from spontaneous combustion are entirely eliminated; and it can be kept with safety anywhere, and for any length of time. Coke is a fuel unlike bituminous coal in its composition, and therefore requires somewhat different treatment when used in place of that fuel. It resembles hard coal, and should be fired in a somewhat similar manner. Some changes in the ordinary grates will probably be necessary to burn coke with maximum economy and convenience, but it can be burned on ordinary grates. The following suggestions will be found useful in learning its management:

1st. In building the fire, put the coke on lightly and often, until the fire is seven or eight inches thick. An eight-inch fire will make steam much better than a heavier one. 2nd. It is better not to disturb the top of a coke fire, therefore when firing, spread the fuel evenly, to keep the fire level. 3rd Shaking bars are very suitable for burning coke, and they should be shaken frequently. If dead bars are used, a light poker should be run under the fire frequently to keep clinkers from clinging to the grate and to keep them broken up. A poker is better than a slice bar for this purpose, as it is lighter and more easily handled. The object is not to bar up the fire, but to detach small pieces of clinker, and prevent them from forming and running together. 4th. It is advisable to keep water in the ash pit or to introduce a jet of steam.

Following is the result of a test made by the Mutual Boiler Insurance Co., of Boston, on the evaporative powers of coals and coke compared with the best soft coals. Steam making value is the only criterion used in making up the table below. The coke is that of the New England Gas and Coke Co., and the value is based on boiler tests and on proximate and ultimate analysis.

COMPARATIVE EVAPORATIVE POWERS OF COALS AND COKE COMPARED WITH THE BEST SOFT COALS.

Soft Coals.	Combustible.	Probable p.c. of Refuse	Coal as Bought.
Pocahontas	100	7½	100
Best Cumberland	100	7½	100
Average Cumberland	98	7½	98
New River	95	5	97
Clearfield	95	10	92
Pittsburg (Youghiogheny)	88	6	89
Ohio (Hocking Valley)	80	6	82
Nova Scotia	83	10	81
Anthracite steam coals and coke—			
Coke (New Eng. Gas & Coke Co)	91	9½	89
Lykens Valley Pea	96	15	88
Lykens Valley Buckwheat	96	18	85
Wyoming Pea	95	15	87
Wyoming Pea, Buckwheat	95	18	84
Schuylkill Pea	93	15	85
Schuylkill Pea, Buckwheat	93	18	82
Lehigh Pea	91	15	84
Lehigh Pea, Buckwheat	91	18	81

The boiler tests are full length tests carefully made on the type of boilers in general use, and with grates suitable for the coke. They indicate a value for the combustible portion of 86 per cent., both when considering the evaporation alone, and when allowance was made for the information given by gas analysis. The proximate analysis indicated a value of 92 per cent. and the ultimate analysis indicated a value of 93 per cent., from which figures we have estimated that 91 per cent. was a fair estimate for the evaporative power of the combustible. The percentage of refuse averaged 9½ per cent. in three boiler tests. Another boiler test showed over 20 per cent. due to unsuitable grates for the size of coke used; but 9½ per cent. appeared to be a fair figure for proper grates, making the evaporative power of the coke 89 per cent. on the basis used in the table.

The capacity of the coke appears to correspond to that of anthracite coal of similar size, and to be about 80 per cent. of the capacity of the best soft coals, such as Cumberland, Pocahontas and New River. By capacity is meant the ability to evaporate steam with a given grate area and draft pressure, irrespective of the economy. In regard to the behavior of the coke, it was found to clinker slightly in a manner similar to the Dominion coal from which it is made, but nowhere near as badly as some of the pea and buckwheat and anthracite coals frequently used.

SAND FILTRATION OF PUBLIC WATER SUPPLIES.*

BY R. S. LEA, ASSOC. M. CAN. SOC. C. E.

(Continued from last issue).

In England and the continent, however, the experience of many years is available, this method, as we have seen, having been used long before the rationale of the process was understood. In England particularly, many of the supplies are from surface waters made available by means of large storage reservoirs; and in nearly every instance the stored water is filtered before being supplied to the consumers. The new supply for Liverpool, which was put into operation in 1892, comes from an artificial lake formed by damming the Vyrnwy River in Wales. This lake is 68 miles from Liverpool, and lies in a sparsely inhabited district remote from railways or towns. Yet the water from this source, safe as it may appear, is also made to pass through a sand filter before being allowed to enter the distribution pipes. In Germany the use of any surface water without filtration is prohibited by law.

But in addition to the high esteem in which the method is held wherever it has been used, there are certain health and mortality statistics which are perhaps of even greater significance. The typhoid fever death rate is now considered to be a pretty good index of the purity of a city's water supply. Keeping this in mind the tables prepared by John W. Hill, M. Am. Soc. C. E. were examined, and the death rate from typhoid

*From a paper read before the Canadian Society of Civil Engineers.

fever of 66 cities in United States and Canada over a period of years studied. These figures show that the lowest rates are for those cities deriving their supply either from springs or from surface waters which have been subjected to sand filtration carried out in accordance with the strictest modern requirements. They also indicate the general inferiority of the water supplied to American cities when compared with European supplies. Chicago and Berlin have about the same population, yet the typhoid death rate of the former is more than ten times that of the latter; or, in other words, the chances of contracting typhoid fever in Chicago are ten times as great as in Berlin. Out of the many instances showing the beneficial effect of filtration with regard to the prevalence of certain infectious diseases, two of the most noted will be cited, one in Europe and the other in America..

Hamburg and Altona, though under separate governments, practically form one continuous city with a joint population of about 800,000. They both draw their water supplies from the sewage polluted Elbe River upon which they are situated. Altona is the nearest to the mouth of the river, and its water intake being three or four miles further down is below the outfall of both its own sewers and those of Hamburg. The Hamburg intake is about two miles above the city. In 1892 an epidemic of cholera occurred, during which Hamburg, with a population of 622,530, had 17,975 cases with 7,611 deaths, while Altona, with 143,000 population, had during the same time 562 cases and 328 deaths, and in many of the cases credited to Altona the disease was contracted in Hamburg. Wandsbeck (20,000), just across the river from Hamburg, enjoyed the same immunity as Altona. Both of these places purify their water supplies by sand filtration, while in Hamburg the only attempt in that direction was the employment of settling basins. A filtration plant was, however, in process of construction at that time, and was put in operation in May, 1893, since when the typhoid rate has diminished from about 30 to 6 per 100,000. The other case is that of Lawrence, Massachusetts, which is situated on the Merrimac River, a few miles below Lowell. In spite of the great dilution, the water of this river which supplies both cities is seriously polluted by the sewage draining into it from the towns built along its banks; and as a consequence the typhoid fever rates in both places were unusually high. In Sept., 1893, a system of intermittent sand filtration was completed. The effect upon the health of the citizens is shown in the following figures:

Year.	Deaths from Typhoid Fever per 100,000 Population.
1887	114
1888	114
1889	127
1890	134
1891	119
1892	105
1893	80
1894	47 (23)
1895	31 (17)
1896	19 (4)
1897	16

For the last four years the figures in the brackets represent the number of deaths among people (principally mill operatives) who were accustomed to drink canal water without filtration; so that the actual reduction in the death rate which should be credited to the filters is much greater even than the figures indicate. Many attempts have been made during the last 12 or 15 years to improve upon the sand filter, but so far without success. Some of the methods invented involve less expense for construction or give better chemical results; but the thoroughness of the bacterial purification effected by the sand bed has not been equalled by any.

The only one of these methods which has been used to any considerable extent is the American or Mechanical System of Filtration, which is employed in several places in the United States. Sand is the material used in this process also, but it is contained in cylindrical iron tanks. The water enters the tanks, usually under pressure, and is driven through the sand at a rate 50 times as great as the maximum allowed in the case of the filter bed. For this reason the latter method is sometimes referred to as Slow Sand Filtration. With such a high rate the surface film must be formed artificially; and this is done by adding a solution of alum to the water, which forms with the carbonates present a white flocculent precipitate. Such a filter will, of course, soon become clogged; but it can be quickly and easily cleaned without removing any of the sand from the tank. The results produced, under test conditions at least, are undoubtedly good; and it has the advantage over the filter bed of somewhat lower first cost. On the other hand, the charges necessary for repairs and depreciation will be considerably higher on account of the less permanent character of its construction; so that if proper allowance could be made for this, the difference in the actual cost of filtering a given quantity of water by either process would not be very great. In any case it will probably not involve an addition of more than 10 per cent. to the ordinary cost of the water. Indeed, calculations have been made showing that if a proper valuation is put upon the lives saved by its use, the construction of a filtration plant is often in the long run a source of economy. Such considerations, however, seem quite unnecessary. A city's water supply should be pure, wholesome, and attractive in appearance, just as the streets should be clean and well paved, and the public buildings architecturally beautiful. Besides, having gone to the expense of obtaining a public water supply, indifference with regard to its purity or unwillingness to provide for it would seem to be utterly unreasonable; especially when it can be secured for such a comparatively small increase in the total cost as sand filtration involves.

It would be much cheaper, of course, to purify only that part of the supply which is used for purely domestic purposes. But that would require a double set of distribution pipes; and we should also lose the satisfaction of knowing that the whole of the public supply could be used for any purpose with perfect impunity so far as health is concerned. And when we consider that the expense of filtering the whole supply only amounts to two or three cents per month for each consumer, it will scarcely be considered excessive.

METAL IMPORTS FROM GREAT BRITAIN.

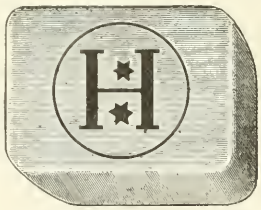
The following are the sterling values of the imports from Great Britain of interest to the metal trades in September, 1898-99, and the nine months ending September, 1898 and 1899:—

	Month of Sept.		Nine Months ending September	
	1898	1899.	1898.	1899.
Hardware	£2,803	£2,018	£17,420	£15,188
Cutlery	3,704	5,538	39,545	39 304
Pig iron	273	5,792	8,386	14,607
Bar, etc.	405	3,288	6,676	14,257
Railroad	2,147	55,311	9,119	113,902
Hoops sheets, etc.	8,059	16,203	44,181	84,510
Galvanized sheets	4,371	8,952	43,712	49,069
Tin plates	5,268	23,394	101,437	141,660
Cast, wrought, etc., iron	3,188	7,435	10,850	39,750
Old (for re-manufacture)	—	1,766	3,574	4,190
Steel	4,203	16,917	30,388	69,677
Lead	4,192	1,657	23,918	34,007
Tin, unwrought	417	4,218	12,292	18,433
Cement	2,859	3,704	17,083	22,643

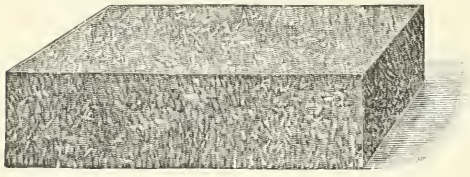
DRAUGHTING.

A most important feature of any engineering or manufacturing establishment is its draughting room. Here the draughtsman prepares the designs for work or machinery it is intended to construct, and on the character and accuracy of the draughtsman's work a great deal depends. For the successful prosecution of his work the artist requires good light and suitable materials. Up to a recent date no Canadian house carried a stock of mathematical instruments and drawing materials adequate to the wants of a manufacturing country such as Canada has grown to be, and supplies of this character have had to be procured from abroad, involving delay and much expense to obtain the same, and not always with satisfactory results. The Art Metropole, of Toronto, has been gauging the wants of manufacturers and engineers in this respect, and has been steadily adding to the stock such articles as leading draughtsmen regard as the best for their purpose. And to-day, it is claimed there is no better stocked house in America in this line than the Art Metropole, Toronto. Here will be found mathematical instru-

ments of the highest grade, the most popular brands of tracing linen, blue print papers, drawing and detail papers, as well as all the lesser accessories such as pens, inks, pencils, rubber, etc., any of which articles may discomfort the user very much, if not of good quality. We illustrate a few things, seemingly small in themselves, but in many cases of great value to a draughtsman.



For example all can appreciate a good rubber, and we here show what is claimed to be the best draughtsman rubber, namely, Hardtmuth's grey pliable rubber, which erases readily without abrasion of the surface of the paper. It may be had in a variety



of sizes. Another rubber indispensable to the artist is a good sponge rubber, which makes a soiled drawing look fresh and new with a few strokes. This is also illustrated. Pens suitable for artists and draughtsmen are also hard to procure, but this

firm carries a full line of everything in this department. Those which are claimed to be the most popular pens for draughting, and for illustration are shown here.

LITERARY NOTES.

A very convincing little circular is that issued by the B. F. Sturtevant Co., of Boston, Mass., regarding their exhaust heads, which shows that by the utilization of centrifugal force in the operation of this head, the water is thrown outward with 1,000 times the force exerted upon the steam, and is thereby absolutely separated from it.

"Modern Buildings of New York City" is the theme of one of the most artistic publications issued in the interests of the valve trade. It contains some fifty pages, and beautiful photo engravings of these buildings are shown, amongst which we notice the New York Life, The Empire, Commercial Cable (21 stories), Postal Telegraph, St Paul Building (25 stories), Siegel, Cooper Co., New York Athletic Club, New York Herald, and Hotels Majestic, Netherland, Savoy, Manhattan Waldorf, Astoria, and numerous other modern edifices in which are used Fairbanks' valves. The Fairbanks' Co., Montreal will be pleased to furnish architects names of architects erecting these buildings in given and others interested in valves, etc., with a copy of the book. We congratulate the Fairbanks' Co. in finding out such a work of art so free from ordinary common place advertising features which so often mar a book of this nature.

Wall Cards, H. & J. published by the Mechanics' Supply Co., Quebec are original in composition, and of great service to parties doing a plumbing. French and English plumbers' supply trade, as well as to machinists' tool users. The names of tools, fittings, furnaces, and valves are given in both languages. The printing is excellent, and the general appearance of the cards make them worthy of a place in any office, machine or plumbing shop.

The annual report of W. Bell Dawson, C.E., engineer-in-charge of Tidal Surveys in Canada, has been issued in the usual Blue Book. It is a report of progress, and as such is welcome. The department is most ably conducted, and the criticisms which are made of its works from time to time in the public press are only criticisms of the small amounts devoted to this service by the Government, not to the way it is expended.

"Small Engines and Boilers" is a manual of concise and specific directions for the construction of small steam engines and boilers of modern types, from 5 h.p. down to model sizes for amateurs and others interested in such work, by E. P. Watson, late editor and proprietor of The Engineer, author of "Modern Practice," "Manual of the Hand Lathe," etc., etc., illustrated, 30 full page working dimensioned drawings. Published by D. Van Nostrand Co., New York.

"The Growing Time in Canada" is the title of a handsomely illustrated pamphlet issued by The Toronto Globe. The public buildings of the various provinces and of the Dominion are shown, as well as points of interest in the chief cities. The engraving was done by Moore & Alexander, Toronto, and is a very fine display of the art.

"The Statistical Year Book of Canada for 1898" has been issued from the Government printing bureau by the Dominion Department of Agriculture. This is the fourteenth year of issue, and, as on each former appearance, the Year Book is more interesting than before. A neat folder gives statistics for the past thirty years of the population, revenue, expenditure, public lands, lands in cultivation, postage, shipping, imports, exports, public debt, expenditure on railways and canals, the working expenses of all our railways, their earnings and profits, full details of chartered banks and postoffice savings banks. Geo. Johnson, F.S.S., is to be congratulated upon the excellent work he is doing in preserving in so compact and convenient form the statistical history of the country.

"A Practical Course in Mechanical Drawing," by William Fox, M.E., assistant professor of Applied Mathematics, College of the City of New York, and Chas. W. Thomas, M.E., instructor in descriptive geometry and drawing in the College of the city of New York. There are numerous illustrations. Published by D. Van Nostrand Co., New York.

Our advertising department has received four handsome wall cards from Jenkins Bros., Boston, Mass. They are issued in the interest of their well known valves, "Jenkens'" '96 packing, and the Sellars' pattern injector.

"The Canadian Home Journal" has passed under the management of a new company, called the Canadian Home Journal Co., and the current number shows that the change is to the advantage of its readers. This journal is now the official organ of the Women's Historical Society, and that department has much information of value to every Canadian who cherishes the records of the country's past. The subscription remains the same, $1 a year.

The 5th edition of the Mechanics' Pocket Memoranda is to hand, published by Colliery Engineer Co., Scranton, Pa. This book is very complete and compact, and is intended for machinists, steam engineers, electrical workers and anyone interested in these and kindred branches will find it of great value. It is bound in pebbled black leather, pocket inside cover, gilt title and edges, and rounded corners.

We have just received No. 4, September, 1898, of Specifications, a half yearly publication of over 700 pages issued, for architects, surveyors and engineers when specifying, and for all others interested in building. This most valuable work is published by the proprietors of the Builders' Journal and Architectural Record, London.

Leaks in metallic pipes can be easily stopped by a patching device, a U shaped yoke being passed around the pipe, with the ends of the yoke carrying a detachable head, with a screw in the centre which presses a cushioned patch over the leak.

NEW RECIPROCATING DRILL AND RATCHET SCREW DRIVER.

This drill is used in drilling steel, iron, brass and other metals, as well as all varieties of woods. It is so constructed that the drill runs continuously to the right, during both the forward and backward movement of the driver, hence drills continuously. The pressure to feed the drill is had by the pressure against the head of the tool, which is provided with ball bearing to reduce the friction. There is no tool made just like it. The chuck is of new design, has three jaws, is accurate, strong, durable, and will not get out of order. No drill points are furnished with this tool—the user furnishing such quality, style and size best suited for work required in wood, iron, steel, brass, etc.

NEW RECIPROCATING DRILL.

The chuck will hold any drill with shank 3-16-inch diameter or less. To open or close chuck move the driver up to chuck, push down the catch in lower end of driver, which holds fast the driver on spindle. After drill is put in chuck and tightened, push up the catch, releasing driver from spindle so it can be moved backward and forward to operate drill. The movement or traverse of the driver is $8\frac{1}{2}$ inches, and full length of tool (without drill), is 16 inches. Every tool guaranteed.

Most ratchet screw drivers made possess one very serious drawback in practical use—that the friction in ratchet mechanism is so great that unless a screw is first made tight in wood by some other means the ratchet screw driver turns the screw out in its backward movement as fast as it is driven in by the forward movement of the driver. The screw is simply turned in and out, no progress made in getting it to its place. The blade of driver instead of remaining at rest during backward movement is carried back by the excessive friction of ratchet and pawls, and the screw with it, except the screw is first driven tight enough in wood to outbalance this friction. Most ratchet drivers are quite noisy in their operation, unhandy to change from right to left, made in a quite limited range of sizes and too high in price to make them popular. This ratchet driver over-

RATCHET SCREW DRIVER.

comes all these faults. The friction in ratchet mechanism is so slight as to be hardly felt, the backward movement is as easy as in a good "stem-winder" and just as noiseless. When a screw is screwed in it stays where put, and is not screwed out when handle is turned back. The construction of ratchet and pawls is such that neither can bend or break, wear or get out of order, and permits a very compact arrangement. The adjustment for right or left hand is exceedingly simple. For right hand or to ratchet a screw in, push the slide to end of slot towards bit; for left hand or to ratchet a screw out, push the slide towards handle of driver. If the slide is placed midway between ends of slot, the blade is held rigidly and the driver can be used as an ordinary screw driver with fixed blade. The materials and workmanship are of superior quality in every detail. The drivers are strong, durable, handsomely finished, and are made in these sizes, 2, 3, 4, 5, 6, 8, 10, 12 inches. North Bros., Philadelphia, are the makers of these new and interesting tools, and in the Aikenhead Hardware Co.'s advertisement on another page, others just as unique will be found illustrated.

—The city of Nicolaiev, Russia, is about to install a complete system of water supply. The water is to be taken from a depth of sixty to ninety feet by a series of wells, a collecting basin, and a standpipe. The plant is to be based upon a supply of about 2,000,000 gallons per day of eighteen hours. The pipe will amount to about sixty miles, dimensions not stated, with all necessary connections and fireplugs. Two pumping engines are specified, with Babcock & Wilcox boilers. Tenders for the plant as a whole or in part will be received for about four months. Interested parties should communicate with V. A. Datsenko, mayor of Nicolaiev, Cherson, Russia.

PAVEMENTS BETWEEN STREET RAILWAY TRACKS.*

BY C. H. RUST, CITY ENGINEER, TORONTO.

In 1891 the exclusive privilege of operating the street railways in the city of Toronto, for a period of thirty years, was disposed of to a company now known as the Toronto Railway Company. The clauses of the agreement, made between the city and the company, that refer more particularly to this paper, read as follows:

"The purchaser shall maintain the ties, stringers, rails, turnouts, curves, etc., in a state of thorough efficiency and to the satisfaction of the city engineer, and shall remove, renew or replace the same as circumstances may require, and as the city engineer may direct. When a street upon which tracks are now laid is to be paved in a permanent manner, on concrete or other like foundation, then the purchaser shall remove present tracks and sub-structures, and replace the same, according to the best modern practice, by improved rails, points and sub-structures of such description as may be determined upon by the city engineer as most suitable for the purpose, and for the comfortable and safe use of the highway by those using vehicles thereon, and all changes in the present rails, tracks and roadbed, construction of new lines or additions to present ones, shall be done under the supervision of the city engineer and to his satisfaction.

"(A). In the event of the purchaser desiring to make any repairs or alterations to the ties, stringers, rails, turn-outs, curves, etc., on paved streets, the purchaser shall repave the portion of the roadbed so torn up at his own expense.

"11. When the purchaser desires or is required to change any existing tracks or sub-structures for the purpose of operating by electric or other motive power, approved by the city engineer and confirmed by the council, the city will lay down a permanent pavement in conjunction therewith upon the track allowance (as herein defined) to be occupied by such new tracks and sub-structures. This shall first apply only to existing main lines and thereafter to branch lines or extensions of main lines and branches, as and when the city engineer may from time to time recommend and the city council may direct and require; but such tracks as are now laid on a permanently formed roadway must, when so required as aforesaid, be changed by the purchaser as hereinbefore provided, without any change of roadbed being made or any expense occasioned to the city thereby."

Under the terms of the agreement the company pays the city treasurer $1,600 per annum per mile of double track and 8 per cent. of the gross receipts. When the receipts exceed $1,000,000, 10 per cent. is to be paid. To raise the money for constructing these permanent pavements debentures were issued, payable in ten years, and the revenue derived from the mileage and percentage of gross receipts is used to pay interest and sinking fund upon these, the total amount of bonds issued up to the present time being $1,210,776, and the annual payment to provide interest and sinking fund is $149,136. This is at present very nearly the amount received from the street railway company, but as these pavements between the tracks will last for a much longer period than ten years, in a few years there should be a considerable revenue derived from this source.

A great diversity of opinion has arisen as to the meaning of the word "permanent," used in connection with pavements. In 1888 this question was in the High Court of Justice before Judge Rose, in a case brought by the corporation of Toronto against the old Toronto Street Railway Company, and after a considerable litigation it was finally settled, without, however, the judge giving his opinion as to the meaning of the word "permanent." When the present company obtained its franchise the interpretation of the word was again subjected to a great deal of discussion, and in 1893 the continuation of the work of changing the rails by the company and the construction of the pavements were postponed from April until August, pending a settlement as to the meaning of this word. The writer has always taken the ground that in this case the word "permanent" refers to pavements with a concrete foundation, and this has since been taken as the meaning of the word as mentioned in these clauses. It is a great pity that this word should be so frequently used in connection with pavements. It would certainly be well in future cases to state explicitly what is a permanent pavement.

*A paper read before the American Society of Municipal Improvements, at the Toronto Meeting

In compliance with the provisions contained in the previously mentioned clauses, in the spring of 1892 plans and specifications for paving the track allowance on King, Queen, Yonge and other streets were prepared, and on the 28th of June, 1892, the Street Railway Company laid down a temporary track on King street, west of Simcoe street, and the contractor for the pavements commenced work. The work of changing the tracks and constructing permanent pavements on the above streets was carried on continuously until winter set in (with the exception of a week's intermission during the time of the Industrial Exposition). The amount of track taken up and relaid this season was 29.9 miles. The rail adopted by the company and approved of by the city was a 6½-inch steel girder rail, weighing seventy pounds to the yard, and having a web three-eighths inch in thickness and a base of 4½ inches wide. A slight alteration was afterward made in the size of the base, making it 5 inches instead of 4½ inches. The rail now weighs about seventy-three pounds to the yard. From experience since gained a heavier section of rail should have been used. The following are the quantities required to build one mile of single track: 114,714 tons of seventy-three pound rails per mile; 5.85 tons of fish plates, seventeen pounds per pair; 1,800 cedar tires; 1 ton of spikes, three-quarters pound each; 1 ton of bolts and nuts, one pound each.

The work of constructing these pavements and the laying of new rails was carried on continuously until the work was practically completed in 1894, there being only a few extensions constructed since. In constructing these new pavements the street railway company took up the old rails, tamped the gravel under the ties, put down new rails and lined and leveled them and the paving contractor did the rest of the work. It may be of some interest to give the amount of work done in each year, the average cost per lineal foot (the width paved being 15 feet for double track), the average rate of progress per day and the different classes of paving material:

1892—20.9 miles single track cost	$322,555 00
1893—26.1 miles single track cost	392,030 00
1894— 9.8 miles single track cost	116,942 61

Average cost per lineal foot of double track for the different classes of pavement during these years was:

Asphalt	$5 23
Granite	2 43
Brick	4 21
Cedar blocks	3 83

This covers the cost of stone or scoria toothing, but where granite was used the contractor was allowed to relay the blocks that were on the street. Average amount done per day was:

Asphalt—131 lineal feet of double track.
Granite—56 lineal feet of double track.
Brick—73 lineal feet of double track.
Cedar blocks—96 lineal feet of double track.

In 1894, on McCaul street, the method of construction was slightly altered as to the system of laying the granite or scoria toothing. It was found that when the blocks were laid as headers and stretchers that the water lodged next to the block and assisted in destroying the asphalt. To prevent this it was decided to lay scoria blocks, 4 x 5 x 9 inches, parallel to the rail, and then lay the asphalt. The practice had been to lay the first six inches of concrete up to the bottom of the rail, then lay the scoria blocks in mortar, and finally put in the remainder of the concrete. On this street a change was also made in this respect. The whole of the concrete was put in at once and while still wet scoria blocks were pounded into it and left to consolidate with the concrete before the asphalt was laid down. In any extension constructed since 1895 wooden ties have been dispensed with and steel tie bars, 2 x ⅜ inches, placed 6 feet apart, are used, the rails being laid on a solid bed of concrete 8 inches in depth by 20 inches wide. This method of construction is much superior to the first type adopted, and is largely used in other cities. After an experience of six years of the different materials used, it is evident that, with the conditions existing in Toronto, asphalt is not a suitable paving material to be used between street railway tracks. After having been down only four years the asphalt commenced to disintegrate. This was at first more noticeable where the asphalt joined the toothing, but it was not long before the rest of the material between the rails commenced to wear into holes. This was due probably to the following causes: The lack of proper foundation under the ties, which was shown by the settlement of the rails in several places, the impossibility of properly tamping the asphalt between the toothing, and the constant watering of the asphalt, rendered necessary by the dust caused by the passage of the cars, and also by climatic conditions. Upon King street, which was the only asphalt pavement laid without toothing, a rut was soon formed, rendering necessary constant repairs. The fact of the lip of the rail not being quite as high as the head, and the gauge of the track being 4 feet 10⅞ inches instead of 4 feet 8½ inches, probably had a great deal to do in forming this rut.

As previously mentioned, the first pavements were laid in 1892, and in 1897 it became necessary to commence tearing up the asphalt and replacing it with granite, scoria or brick, depending upon the amount of travel upon the street. By 1900 all the asphalt between the rails will have been replaced by a more permanent material. Up to the present time seven and one-half miles of this work have been done. As these asphalt pavements were guaranteed for five years, arrangements were made with the contractors whereby they substituted brick for this asphalt, and were paid $1.50 per square yard, but afterward when the guarantee expired the price paid for substituting scoria for asphalt averaged about $2.40 per square yard. This includes taking up the old asphalt and also four inches of concrete. The amount of money spent up to the present time in substituting a more permanent material than asphalt is $137,340.19. In putting in blocks in place of asphalt, the asphalt was first taken off and then the concrete had to be picked out so as to afford room for the blocks, which were bedded on a cushion of sand. Fortunately, on most of the streets the concrete was put in between the rails just to a depth of four inches, and it was not a very difficult operation to take this out. Granite is no doubt the most durable material to use between street railway tracks, but owing to the very strong opposition of the cyclists to this material not so much of it was used as the department would have liked, and scoria blocks, imported from England, were used instead. On streets where there was not a great deal of travel Canadian bricks were used. Cement grout was almost entirely used for this work, although some filling was done with paving pitch; but cement was found to be the most satisfactory. Owing, however, to the impossibility of stopping street car traffic while this work was in progress, it was very difficult for the filling to become properly set. On King street during the past summer, where we were substituting scoria block for the asphalt, a portion of the pavement between the tracks was laid with concrete. It has been down now some two months, but not long enough to know the result.

ORIGIN OF THE B. GREENING WIRE CO., LTD.

Wire, in its various manufactured forms and composition, has during the present generation become so important a factor in some of the great inventions and engineering achievements, that a few facts as to its uses and manufacture may be interesting to many of our customers. It is but within the present century that the electric telegraph, the ocean cables, the great suspension bridges, the useful and important telephone, the electric railroads, the drilling for natural gas, the making of wire fencing, nails, etc., has created such an immense demand for this article, and stimulated an industry that now takes such high rank amongst manufactures. The art of making wire has been traced back to the year 1700 B.C. Gold wire decorated the sacerdotal robe of Aaron. A specimen of wire, made by the Ninevites 800 years B.C., is exhibited at the Kensington museum, London, England. Homer and Pliny referred to similar productions in their early writings. Metal heads, with imitation hair of wire recovered from the ruins of Herculaneum, are in the Portici museum, Naples. From such remote eras up to the fourteenth century, wire in its general acceptance was produced by hammering out strips of metal, and not by the process of "drawing," as now practiced. In the middle ages this industry was extensively pursued, and the artificers thus engaged were termed wiresmiths, but in the earliest days of the manufacture, gold, silver and bronze appear only to have been used. It is substantiated by technical records that the present method of drawing wire was practiced in the Lenne district of Germany during the fourteenth century, and about the year

1350 a wire drawing mill was erected at Nuremburg by a man named Rudolph.

The first needle manufactory in France was started by an Englishman, named Christopher Greening, at St. Omer, and the town recently celebrated the four hundredth anniversary of the establishment of the industry. About 1600 A.D., it is recorded that at Tintern Abbey on the Wye, pins and needles were manufactured by one Greening by name. In the year 1630, a proclamation was issued by Charles I. to the effect that the home industry had made such advancement that further imports of wire were prohibited. About the year 1799, Nathaniel Greening, who came from Tintern Abbey, commenced the manufacture of wire at Warrington. A few years later the firm of Greening & Rylands was established, and carried on business until the year 1840, when the partnership was dissolved, Mr. Greening taking his sons into business, and establishing the firm of N. Greening & Sons; Mr. Rylands' sons continuing under the firm name of Rylands Bros. It was with the firm of Greening & Rylands that the late Benjamin Greening, second son of N. Greening of the firm in question, served a seven years' apprenticeship as a wire drawer; then, commencing business for himself, continued until 1858, when he removed to Canada, and became one of the pioneers of the wire industry here. Under the firm name of B. Greening & Co. he commenced the drawing of wire, wire weaving and rope making, and for many years carried on a successful and steadily increasing business until his death, in 1877, when he was succeeded by his son, S. O. Greening, who built new works and added many new lines to their already extensive business. In 1889, the B. Greening Wire Co. was incorporated as a joint stock company, with Samuel Owen Greening as president, since which time important additions have been made to their buildings and machinery.

THE BRITISH FIRE PREVENTION COMMITTEE.

The British Fire Prevention Committee, under whose auspices tests of materials are conducted, was founded after the Cripplegate fire, London, of November, 1897, and was fully incorporated early this year. It counts a membership of some five hundred architects, surveyors, engineers, municipal officers and others directly or indirectly interested in fire prevention, among whom are practically all the leading members of the professions named. The offices are at No. 1 Waterloo Place, London, Eng., where the library includes a file of some sixty technical journals from all parts of the world, and the regulations and building acts, etc., of all countries. Regular publications are issued by the committee (over thirty already having appeared), and business meetings are frequently held. The founder was Edwin O. Sachs, the architect. Three of the primary objects of the committee are defined as follows: To direct attention to the urgent need for increased protection of life and property from fire by the adoption of preventive measures. To use its influence in every direction towards minimizing the possibilities and dangers of fire. To undertake such independent investigations and tests of materials, methods and appliances as may be considered advisable. It is with the idea of meeting these objects that a testing station has been established. The present tests will be of an entirely independent character, arranged on scientific lines, but with full consideration for the practical purpose in view. Absolute reliability will be assured, records being mostly taken automatically, or by photography, and the temperatures being easily regulated by the application of gas. All reports on tests solely state the bare facts and occurrences, with tables, diagrams and illustrations, and on no account will reports include expressions of opinion, or any expressions that might be read as comparisons or criticisms. The general arrangement and direction of the tests is in the hands of the executive, and in accordance with certain principles laid down after careful study and experiment. The actual tests are attended by the members of the council and the members of the committee in rotation, care being taken that the attendance is always thoroughly representative of the technical professions primarily interested in the specific object under investigation. As to the financial aspect of the station, the establishment expenses have been met by a special subscription which will also cover the expense of conducting tests of general technical interest. Tests with patented materials, makers' systems, etc., are, however, subject to a scale of charges, but these charges are so figured as to only just cover the actual cost. The services of the members conducting or attending tests are given gratuitously. In the first six months' work at the testing station no less than 27 official tests were undertaken, and the results were embodied in twenty reports. Of these 27 tests there were 5 with floors, 2 with ceilings, 4 with partitions, 7 with doors, 8 with glazing and 1 with treated wood.

THE ENGINEER'S AND ELECTRICIAN'S HAND-BOOK, A REFERENCE DIRECTORY.

When the Canadian Association of Stationary Engineers a couple of years ago determined to publish a hand-book containing in a convenient and compact form a great deal of information which successful stationary engineers require to be familiar with, a number of our leading business houses, whose specialties brought them in close contact with the engineers, such as engine and boiler makers, pump manufacturers, manufacturers of dynamos and electrical machinery, elevators, radiators, belting, oils and engineers' supplies generally, took the opportunity which was offered them of placing their products permanently before the engineers, by securing advertising space in the volume. At the same time they gave tangible expression of their good will to the engineers by aiding in the publication of a work which was of great educational value. The time that the stationary engineers had at their disposal for preparing such a work being limited, it was found necessary to place the business arrangements in the hands of an agent. The members of the committee which had the matter in hand were, James Milne, A. E. Edkins, E. J. Philip, Albert Slute, A. M. Wickens, S. Thompson, Wilson Phillips and Secretary J. W. Marr, of Toronto No. 1. The agent employed was W. H. McCarthy, with whom the committee made such liberal terms as to entirely free the society from the suggestion that the venture was in any sense a commercial one. The educational features were paramount and the good of the order was the only object sought.

The agent's work was rendered very light, because the credentials given him by the committee were in most cases sufficient to ensure his receiving an order for an advertisement when they were presented to those, who, as we have already explained, were interested in the success of the project. We append the letter of introduction given the agent:

Toronto, Sept. 13th, 1897.

To Whom it May Concern:

This is to certify that the bearer, W. H. McCarthy, is authorized to solicit advertisements for Engineer's Manual, to be published under the auspices of the Canadian Association of Stationary Engineers, and to collect for such advertisements on publication of said Engineer's Manual.

Given under our hand and seal this 13th day of September, 1897.

[Copy].

JOHN W. MARR,
Secretary, Toronto No. 1, C.A.S.E.

Notwithstanding the generous terms made with the agent, the association was obliged, after the publication of the book, to enter suit in the Division Court, their solicitors being McLean & McCallum, to recover from Mr. McCarthy the small percentage of the receipts which was the association's share of the proceeds. It was impossible to serve a writ, however, as the defendant had removed himself beyond the jurisdiction of the Court.

A short time ago one of our advertisers handed us a shabby volume without an index, whose pages were not even numbered. Its title set forth that it was the Engineer's and Electrician's Hand-Book and Reference Directory, provincial edition, compiled and published by the Reference Publishing Co. The reading matter in the volume seems to have been selected at haphazard from former hand-books, from technical journals and from the household columns of the country weeklies. Such valuable bits of information as the following are happily illustrative: "To soften old putty in sashes—run a red hot iron over it and it will peel off easily." "To find the weight of a grindstone 4 feet 6 inches in diameter, 7 inches thick," etc.

The chief interest in this literary venture lies, however, in the fact that many of the leading advertisers in the Engineer's

Manual, compiled by the Canadian Association of Stationary Engineers last year, are also found in the pages of this unfathered publication. Almost at the same time as we received the Reference Directory, we received the following letter:

Editor Canadian Engineer:

Sir:—There have been a number of enquiries lately about an engineer's hand-book. I am authorized by the Book Committee to state that the C.A.S.E. have not issued a book this year, neither have they authorized any person to get one out for them.

Yours respectfully, W. J. Webb,

October 26th, 1899. Secretary Toronto No. 1.

The columns of The Canadian Engineer have been at the service of the C.A.S.E. since the formation of the association, and we determined to investigate a matter so closely affecting its interests, and also those of the commercial world generally. The majority of advertisers in the Engineer's and Electrician's Hand-Book and Reference Directory were found to be under the impression that this book was being brought out under the auspices of the C.A.S.E., because the volume shown them when canvassed by the advertising solicitor was a handsome leather-bound copy of the Engineer's Manual of the year before, and the solicitor was W. H. McCarthy, who had been the agent of the C.A.S.E. the year before. A rumor, which we were unable to confirm owing to the advertisers being out of town, states that the original letter was also used to secure advertisements.

Several of the advertisers, such as the Jubilee Grate Bar Co. and the Downer Pattern Works, having become suspicious of the bona fides of the publication, refused payment for the advertisement and the copies of the book ordered, claiming that they had believed the book to be published by the C.A.S.E., and that the books delivered were very inferior to the sample submitted. Suit has been entered to compel payment in these cases, and a number of adjournments have been granted at the request of Mr. McCarthy's solicitor, he being out of the country, where he will probably remain.

Other advertisers only discovered the true state of affairs during the course of our investigation. They had unhesitatingly paid their accounts, being fully persuaded that the Reference Directory was published by the C.A.S.E. Among minor irregularities perpetrated we found that limited editions were gotten up for delivery to special advertisers, who believed the terms of their contract were similarly carried out in the whole edition. G. F. Haworth, of Sadler & Haworth, in placing his advertisement had stipulated that in consideration of the price paid no other advertisement of leather belting was to appear. There certainly is no other such advertisement in the fifty copies which were furnished to Sadler & Haworth, but the Beardmore Co.'s advertisement appears on the back cover of all other copies of the issue which we have traced. Norman G. Macleod, with the Beardmore Belting Co., Ltd., assures us that he was told by Mr. McCarthy that the C.A.S.E. was publishing the work, and Mr. McCarthy sold him the space in the book which is now occupied by Sadler & Haworth, afterwards offering to move the Beardmore Belting Co.'s advertisement to the back cover without charge. Thus he carried out his promise to give Sadler & Haworth the only advertisement of leather belting in the book. The following firms have been interviewed by a representative of The Canadian Engineer, and all tell practically the same story of misplaced confidence. In some cases the prices paid were one hundred per cent. greater than others: Beardmore Belting Co., Sadler & Haworth, E. Rogers & Co., Coulter & Campbell, Mica Boiler Covering Co., Aikenhead Hardware Co., Jubilee Grate Bar Co., Reid & Brown, Westman & Baker, Downer Pattern Works, Dodge Mnfg. Co., Redpath, Reid Automatic Smoke Consumer Co., Pendrith & Co.

The other firms whose advertisements appear in the Reference Directory, but whom time or circumstances have prevented us calling upon are: Canada Metal Co., Rice, Lewis & Son, Morrison Brass Co., Burns & Co., Conger Coal Co., Standard Fuel Co., Royal Electric Co., United Electric Co., P. H. Patriarche Boiler Insurance Co., St. Lawrence Foundry, Luxfer Prism Co., A. R. Williams, Queen City Oil Co., Canadian Rubber Co., Chas. H. Riches, B. & H. B. Kent, and Fetherstonhaugh & Co.

We are sure that the full account of this affair which we have given will be of interest, not only to those directly affected but to all who recognize legitimate advertising as the path to success in business. Too often wide-awake business men invest money in advertising without any of the careful investigation which they would bring to bear on any other transaction involving a similar amount. In this way grave injustice is done to legitimate advertising mediums, which have been built up by great expenditure of time and money.

THE EVERETT COKE WORKS.

The coke ovens at Everett near Boston, Mass., which H. M. Whitney stated some time ago would soon use three-quarters of a million tons of Nova Scotia coal a year, are described in a recent issue of The Mining Record: Four only of the many by-products of coal are sought for at the works, namely, coke, gas, tar, and sulphide of ammonia. All of the tar is disposed of to the National Tar Company, while for the ammonia there is a ready general demand. As yet little or no gas is being disposed of, as connections with the mains of other gas companies have not been completed. On the wharf there are towers for discharging, of the same kind as those erected by the company at Montreal. There are also coal pockets for receiving coal. From the towers the coal is conveyed in tubs by means of an endless rope to pockets situated about the centre of the coke oven plant. From the towers the tubs run until a pocket is reached into which the coal is discharged. The empty tubs do not return by the road they came, but continue on and go up an incline on the opposite side. When an oven is to be charged an iron car, hopper-shaped, is run under a chute—or the pocket—filled and run to the particular oven, as required. The car contains six tons of coal, which is the quantity necessary to a charge. When the coke is ready a steam ram shoves it out into a peculiarly constructed, movable, chute shaped car, with a movable gate at foot, to prevent the coke from running over on to the railroad underneath. This car is, say, thirty feet long. As the coke comes from the oven it falls on, and runs down and over the iron sheets on the car. As the coke fills the space on the car in front of the oven door it is moved along until the whole surface of the car is covered with coke. During the time of discharging water is poured on to cool the coke. The coke comes out of the oven in an almost solid mass, but breaks some, of course, on falling into the car. After the coke has cooled sufficiently, the iron gate on the car is lifted, and the coke runs into railway coke cars. After January, 1900, there will be 400 ovens, which will require no less a quantity than 2,400 tons of coal daily. This, after making allowance for an occasional oven being allowed to cool for repairs, will bring the quantity of coal necessary, in charging the ovens for a year, up to 750,000 tons, the quantity stated by Mr. Whitney that would be required. With so much favor has the coke, for locomotive and other purposes, been received, that it is in contemplation to erect an additional 400 ovens. That would mean an annual consumption of coal of 1,500,000 tons, and an annual revenue to the province of the large sum of $187,500. The gas made so far has been employed chiefly in the burning of the coke, and in heating the uncharged ovens. Each ton of coal produces 10,000 feet of gas. Of this quantity 48 per cent. returns to the ovens, to produce heat. The more gas returned to the ovens the quicker made is the coke. When all the ovens have been heated 50 per cent. of the gas made will be returned for the purpose of quicker burning. This will leave 5,000 feet of gas, for heating and lighting purposes, for every ton of coal coked. In other words the company will have for disposal, after the 1st of January, the large quantity of 12,000,000 feet of gas daily, a quantity much larger than is consumed by all of Boston and its environs.

The Berlin, Ont., Rubber Mnfg. Co., Ltd., has almost finished installing its plant and already some 75 tons of machinery are in place. The main building is white brick, three stories, 158.53 feet; the boiler-house is 48 x 50 feet, with a chimney 100 feet high. The contract for the motive power went to Goldie & McCulloch, Ltd., Galt. There are two large horizontal return tubular boilers of 130-h.p. each. These boilers will be fired by two Jones underfeed automatic stokers, supplied by the General Engineering Co., Ltd. On the premises is an 8-inch artesian well, 255 feet deep, to supply water. The officers of the company are: J. Kaufman, president; A. L. Breithaupt, secretary-treasurer, and George Schlee, manager.

Industrial Notes.

The gas company at Sarnia, Ont., is laying larger mains.

Willis Chipman, C.E., has prepared plans and estimates for waterworks in Gananoque, Ont.

R Dillon, Oshawa, Ont., maker of saw sets and cross-cut saw handles, is putting in a plant for forging bolts, nuts, etc.

The Imperial Paper Mills, Sturgeon Falls, Ont., want that town to give them an additional bonus of $12,000 with several other privileges.

The dam of T. G. McMullen's pulp mill at Union, N.S., was carried away October 14th. It will not be rebuilt before next summer it is said.

The Maritime Clay Works, at Pugwash, N.S., are under contract to supply the Dominion Iron and Steel Company with 7,000,000 bricks.

Ritchie & Ramsay, manufacturers of coated papers, New Toronto, have erected an extension 100 x 60 feet, three stories high, to their factory.

The heating apparatus in the Penetanguishene, Ont., Reformatory has been changed from wood to slack coal burning. A considerable saving will be effected.

The Waterloo, Ont., water tower will be 115 feet high, diameter, 20 feet; capacity, 225,687 gallons. Hunter Bros., of Kincardine, are the contractors. The cost is $6,000.

The Syracuse Smelting Works, Montreal, are now running day and night. Orders received by the company before the annual inventory is taken will be filled at special prices.

The grist mill recently completed by R. J. McDougal & Son, Lancaster, Ont., is supplied with power by a 20-h.p. gasoline engine, manufactured by Goldie & McCulloch, Ltd., Galt, Ont.

It was stated some time ago that a well-known hardware merchant of Halifax, N.S., and another of Dartmouth, N.S., were about to put up a rolling mill at the latter town. The Maritime Merchant now announces that they will establish a steam laundry.

Oelschlager Bros., Berlin, Ont., are putting in an elevator at Schaefer, Killer & Co.'s, Waterloo, and one into C. H. Doerr & Co.'s, Berlin, biscuit factory, and have an order for a two ton elevator from the Berlin Rubber Co.

September, 1899, is the banner month for business in the history of the Austin Separator Co., Detroit, Mich., manufacturers of steam and oil separators. The Austin is one of the oldest baffle plate separators on the market, and one of the most popular.

Fred. C. Beresford, London, Ont., superintended the drilling of ten wells for the Berlin, Ont., waterworks. The wells are an average of 150 feet deep and will furnish a daily flow of 1,000,000 gallons. Berlin has hitherto had a water supply from a small lake. The well water is said to be of very fine quality.

Waterloo, Ont., has leased a suitable lot for a furniture factory to the furniture firm of Lippert & Pommer for a term of ten years at a rental not to exceed the school taxes on the lot and building. At the end of the ten years the lot will be deeded to the company if they are still in business and employ at least twenty-five skilled workmen.

J. M. Ruddock, of the Miramichi Foundry and Machine Works, was the successful tenderer for the super structure of the new steel bridge across the Nashwaak at Marysville, N.B. There will be four spans of 112 feet each and one span of 43 feet. The work will be done at Chatham, N.B., and taken to Marysville by the Canada-Eastern railway for erection. The price is about $25,000.

The buildings of the Cushing pulp mill, near St. John, N.B., which will be complete by the end of the present month, cover 56,517 square feet, and comprise the following buildings: Machine, 180 by 66 feet; screen, 144 by 60 feet; blow-off, 144 by 30 feet; digester, 144 by 28 feet; wood, 160 by 45 feet; boiler, 131 by 75 feet; engine, 50 by 60 feet; chemical, 156 by 50 feet. The chimney is to be 200 feet high, and a wharf 370 feet long is being built. The output will be 50 tons of pulp daily, and 250 men will be employed.

Fisk & Co., curriers and fine feather makers, Montreal, are asking Lachine, Que., for a bonus of $25,000 to establish a factory in Lachine to employ 60 people, and pay $35,000 annually in wages.

Edmonton, N.W.T., is offering free site and exemption from taxation for ten years to anyone who would erect and maintain a fully equipped foundry and machine shop within the corporation limits.

J. H. Wilcox, H. Buckel, J. E. McGarvin, F. Wilcox, Alice M. Buckel, Toronto; J. Buckel, New Hamburg, Ont., have been incorporated as the Cyclone Woven Wire Fence Co., Ltd.; capital, $30,000; chief place of business, Toronto.

Last winter the Goldie & McCulloch Co., Ltd., Galt, Ont., sold a "Model" gasoline engine to D. P. Tobin for cutting ice. So well did the experiment work that the company has shipped two more to Mr. Tobin to be used for the same purpose this season.

D. A. Ripley, Pittsburg, U.S.; G. W. Burkhart, J. P. Warrick, Detroit, U.S.; H. S. Warrick, W. A. Smith, Kingsville, Ont., and S. H. Chisholm, Cleveland, U.S., have been incorporated as the Ontario Glass Co., to make glass in Kingsville, Ont.; capital, $100,000.

The Prescott, Ont., waterworks are now practically complete, and water will be turned on about the end of the month. Wm. Watson, whose name is familiar to all readers of our columns as a writer on sanitary matters, has been engaged on the works as inspector for the engineers during construction.

The Carborundum Co., Niagara Falls, N.Y., and Ontario, has just issued a neat little booklet, which shows that carborundum, though a higher priced abrasive than emery, is rapidly increasing its sales. The pamphlet contains a number of letters which say that carborundum wheels are the best in use.

St. Henri, Que., has bonused the Lang Biscuit Manufacturing Company, Montreal. The council exempts the company from all municipal taxes for ten years, the company undertaking to build a factory in the town, and to expend at least $100,000 annually in wages. The company has bought part of the Drummond property, and will erect a building four stories high.

W. McDonald and D. McGregor, Westville, N.S.; R. Bell, D. R. Campbell and J. H. Marshall, St. John, N.B., have been incorporated as the Maritime Glass Co., to carry on the manufacture of ornamental glass by bending, staining, silvering, cutting, etc.; capital, $15,000; chief place of business, St. John, N.B.

Colin Campbell, St. Hilaire, Que.; G. R. Starke, R. D. McGibbon, Q.C., J. A. Prevost and Victor E. Mitchell, barrister, Montreal, have been incorporated as the Arlington Cab Co., Ltd., to buy the business of the Arlington Private Cab Stables, and establish a line of automobile cabs to ply for hire in Montreal; capital, $100,000; chief place of business, Montreal.

Ernest Rolph, of Sproat & Rolph, architects for Lever Bros., of Sunlight Soap fame, has let the following contracts, amounting to over $140,000: Carpenter work, W. & J. Clarke, Toronto; masonry, Cannon & Sons, Toronto; steel structural work, about $50,000, Hamilton Bridge Co., Hamilton; roofing, Forbes Roofing Co., Toronto; galvanized iron work, Douglas Bros., Toronto; soap machinery and soap pans, Jno. Inglis & Sons, Toronto; Heine boilers will be used.

The Goldie & McCulloch Co. has at present a number of large orders for flour milling machinery. Among these are the equipment for a 175 barrel mill at Saskatchewan, N.W.T., to be known as the Farmers' mill, which will be installed in a few weeks; a 50-barrel mill at Leduc, N.W.T., for J. P. Findlay; a 150-barrel mill at Brantford, Ont., for Wood Bros., which has just been put in; and for the Dowling Manufacturing Co., at Edmonton, N.W.T., a mill with a capacity of 175 barrels of flour per day, now being installed. Quite a number of other orders, for smaller mills in various parts of Canada, are also being filled.

The Sissiboo Pulp and Paper Co., which made a successful flotation of stock last month, will absorb the property of the Sissiboo Falls Pulp Co., at Weymouth, N.S., and will build a new mill three miles further down, operating both. The two will have a combined capacity of forty tons of dry pulp per day or about 12,000 tons annually. The work of erecting the new mill will be commenced at once, so that it will be in operation next year.

The Hamilton Bridge Company has taken out a permit to build an addition to its works.

There will be a million dollar station and hotel built by the C.P.R. in Winnipeg next year.

Arrangements are said to be under way for the establishment of a beet sugar refinery at Aylmer, Ont.

The contract for the new sulphite pulp mill buildings at Sault Ste. Marie, Ont., has been let to W. J. Hill.

A great deal of building has gone on in Petrolia, Ont., during the past season.

It is proposed to organize the Lambton Co-operative Creamery Co. among the farmers in the neighborhood of Petrolea, Ont. The capital stock will be about $25,000.

The electrical fountains put into the Crystal Palace, London, Eng., are supplied by pumps built by the Goulds Mnfg. Co., Seneca Falls, N.Y.

A neat folder containing particulars of the large leather belt being made for the Ogilvie Milling Co. has been issued by Sadler & Haworth.

The market for iron and steel scrap is reported very active by the Syracuse Smelting Works, Montreal, which company is large buyers of these materials.

The House of Refuge for Ontario county will be built in Port Perry, Ont., that town having offered a bonus of $5,000, and a free site. The building will cost $20,000.

The Dominion Government has placed an order for an iron show case with the Goldie & McCulloch Co., Ltd., Galt, Ont., to contain the mineral display at the Paris Exhibition.

Fifteen large bagasse filters for sugar plantations in Mexico have just been shipped via New York and Vera Cruz by the Goldie & McCulloch Co., Ltd., Galt, Ont. The same firm has on hand an extensive order for special machinery for the St. Charles Condensing Co., which is building a branch in Ingersoll, Ontario.

F. C. Billings, superintendent of the famous Billings & Spencer works at Hartford, Conn., manufacturers of fine steel drop forgings, writes of the Yankee Twist Drill Grinder, described in our September number: "It is the best drill grinder Billings & Spencer have ever used." This grinder is sold by the Fairbanks' Co., Montreal.

Shurley & Dietrich, Galt, Ont., are now supplying their eastern trade from the Beaver works in Sherbrooke, Que., recently taken over by them. They will also make axes in Sherbrooke. They are also removing the iron bedstead factory from St. Catharines, Ont., lately bought from the R. H. Smith Manufacturing Co., and are putting up a large stone building in Galt for its reception.

The Goldie & McCulloch Co., Ltd., Galt, Ont., is turning out some very large engines of late. Among others are engines for the Vulcan Iron Co., Winnipeg; R. C. Ennis, Neepawa, Man.; the town of Barrie and the town of Prescott; Berlin Rubber Co., Berlin, Ont.; Dominion Bridge Co., Lachine, Que.; Kennedy & Sons, Owen Sound, Ont.; Intercolonial Railway Co., St. John, N.B., and the Standard Shirt Co., Montreal.

During the last two years the development of trade in connection with the Albion Iron Works, Victoria, B.C., has been little less than phenomenal, says The Toronto Globe recently. In 1896 the company were employing about 90 men. To day they have about 260 men on their pay roll. In addition to this they have within the last two years added to their plant, involving an expenditure of $75,000. For the last two months they have had shifts working night and day in order to keep pace with their orders.

It had been cabled from London that there was an extraordinary military parade at Aldershot October 31st, when 15 traction engines and 40 trucks were inspected previous to their departure for South Africa. A stretch of sandy, rocky road was selected for the tests and gave an excellent chance to observe the points of the engines. A steep ditch and banks, two and three feet high, were safely traversed. Though at times the wheels sank to the deep other engines pulled out the disabled ones. The Duke of Connaught and Prince Louis and Victor Napoleon attended the trials, and were much pleased with the result. Twenty four of these engines will be despatched to South Africa.

The B. F. Sturtevant Co., of Boston, Mass., has issued a circular relating to its exhaust heads, which makes clear the efficiency of centrifugal force as a means of separating water and steam.

The Waterloo, Ont., Manufacturing Co., agricultural implement makers, has decided to build an addition to its factory, 200 x 60 feet, two stories high. One story will be completed this fall.

The new buildings erected or in process of erection since January 1st, 1899, in Vancouver, are stated by The World to be valued at $2,475,000, and the value of the municipal improvements also being undertaken at this time amount to $280,000.

There will be three ventilating shafts placed in the northern part of Toronto to ventilate the sewers which in the upper portions of the city at times emit a horrible stench. If this experiment proves successful these ventilating pipes will be generally introduced.

There is a very large prize offered for the best plans for a system of waterworks, drainage and electric lighting for the town of Levis, Que. The prizes are $1,000 for the best and $500 for the second best plan. The details will be found in our advertising columns.

E. Dowling, W. Dowling, R. P. Ottewell, J. H. Dowling, J. B. Dowling and H. W. Dowling, farmers, Northwest Territory, have been incorporated as the Dowling Milling Co., Ltd., with a total capital stock of $40,000, headquarters in the Edmonton Settlement, in the District of Alberta, N.W.T.

The L. S. Starrett Co., Athol, Mass., U.S.A., has decided to discontinue the manufacture of milling cutters, and has sold the stock, machinery and good will of the cutter department to F. J. Gay, for the past five years a partner with them in that branch, and also manager of it. E. T. Ward is to be associated with him under the firm name of Gay & Ward. The L. S. Starrett Co. is confining itself to the manufacture of fine mechanical tools already fairly known in Canada to machinists and the tool supply trade.

The Association of Architects of the Province of Quebec opened its new rooms in Montreal a short time ago by holding a reception, which was attended by members of the association and a number of distinguished guests. Invitations had been given to the president of the Royal Canadian Academy, who was present, and to academicians in Montreal; to the office-bearers of the Art Association, of the Canadian Society of Civil Engineers, and of the Renaissance Club; Dr. Bovey, dean of the Faculty of Applied Science at McGill University; Professor C. H. McLeod, P. W. St. George, the professors of the Ecole Polytechnique, etc. The president of the association, Professor Capper, of McGill University, received the members and their guests.

One of the reasons why Canadian pulp is now so much in demand in England is because of the enormous cost of pulp wood in Sweden, the former source of supply. Formerly a cord of pulp wood, 4 x 4 x 8 ft. cost in Sweden $2.50. Now it costs $10. The industry has so reduced the supply in that country that a reduced cut and practically prohibitive prices have resulted. An instance is given in a contemporary of one English mill in Sweden that had 600,000 logs last year for pulp purposes. Of this lot 300,000 were only five inches at the top, thus showing that the larger trees are getting very scarce. A representative of an English firm lately made contracts in Nova Scotia, it is said, for 25,000 tons of pulp to be delivered next year.

F. S. Evans, of the F. & D. Bicycle Co., recently stated that the very large trade in Canada previously done by the companies now incorporated in the American Bicycle Co. is to be preserved and continued by a syndicate of Canadian capitalists, who have purchased for Canada from the American Bicycle Co. all their patents, rights, good will, and business, and will immediately establish in Canada a complete manufacturing plant, capable of turning out not less than 30,000 bicycles per year. In addition to this plant, the plants of the Canadian Typograph Co., manufacturers of the F. & D. bicycle, the E. C. Stearns Co., and the Wheeler and Christy Saddle companies, will be taken. This plant will be established in Canada in two months. Toronto has been chosen as the site, if suitable buildings can be secured. The company will have a capital of $2,500,000.

The engine in S. G. Parkins' shingle mill, Lindsay, Ont., was wrecked by the breaking of the belt which drove the governor. This threw off the main belt, and the engine raced with the result stated.

After the 15th of November the headquarters of the Canada Cycle & Motor Company, Ltd., will be at the southeast corner of Bay and Front streets, Toronto. They have leased the entire building containing about 25,000 square feet. The entire management for all the factories will be concentrated here, and the offices are now being made ready for the accommodation of the staff. Meanwhile they are occupying temporary quarters on the fourth floor of the Canada Permanent Building, 18 Toronto st.

Marine News.

There appears to be every prospect of the building of the southern portion of the Trent Valley canal.

Angus MacAuley, Southampton, Ont., has received the appointment as captain of the Government Upper Lake patrol boat "Gilphie."

The Richelieu and Ontario Navigation Company paid a dividend of three per cent. out of the half year's profits on the 2nd of November.

The directors of the Quebec, Hamilton and Fort William Navigation Company have accepted the tender of an English firm to build two vessels at a cost of $275,000.

The corporation of North Vancouver is submitting a bylaw to the voters of the district to borrow $12,000 to be used in buying and operating a ferry steamer between Vancouver, B.C., and North Vancouver.

M. Connolly, who has the contract for dredging and building the Government wharf at St. John, N.B., says that he will have the dredging completed and the stone work of the wharf sufficiently advanced to permit of a vessel coming alongside, during the present month.

An order has been placed by the Lodestar Co., Kaslo, B.C., in Liverpool, Eng., for the construction of a hull, boiler and machinery for a new steel steamer, which is to arrive in Kaslo about the end of February next, when she will be put together. The steamer will be 65 feet long and 16-foot beam.

It is reported that the contract for the extension of the Lorne Graving dock, at Levis, is to go to Thomas Powers, Levis, Que., the lowest tendered. Departmental estimates are $117,000, but it is said Powers' tender is above this figure. The dock is to be lengthened from 445 feet to 600 feet.

J. J. Long, president of the Collingwood Dry Dock Company, stated recently that arrangements were about completed for establishing at Collingwood a modern shipbuilding plant of large proportions. Alexander McDougall, Duluth, formerly general manager of the American Steel Barge Company, will be a director in the company. The dry dock will be taken over by the new company.

The water front at the foot of Yonge street, Toronto, known as Pier No 21, will hereafter be called the Richelieu and Ontario Navigation Company's dock. With the new management there will also come new alterations and additions to the wharf. From the foot of Scott street and extending for a distance of 300 feet a new wharf will be built adjoining the present structure. When this is completed it will provide an excellent berth for the palace steamer "Toronto."

The Canada Atlantic Transit Company, recently incorporated, has elected officers as follows: President, J. R. Booth, of Ottawa; vice-president and counsel, H. F. Stevens, St. Paul; secretary, J. T. Rose, Duluth; treasurer and assistant secretary, C. T. Fleck, Ottawa; assistant treasurer, W. H. Burk, St. Paul; general manager, E. J. Chamberlain, Ottawa. Most of the officers are connected with the Canada Atlantic Railway Company, with which it will operate. The company has operated the Menominee fleet of six boats since early in 1897, between Duluth and Parry Sound, and Chicago and Parry Sound. This fleet was recently sold to the National Steel Company, and the Canada Atlantic has purchased the "George Orr" and "Arthur Orr." They will purchase four more vessels.

T. W. Paterson, manager of the Victoria & Sidney railway, states that the company has decided to build a steamer to be on the route by the 1st of February, which is to be a screw vessel, 90 feet long by 20 feet beam, and fitted both for freight and passenger service. Her machinery will be built in Toronto. When on the route she will make two round trips a week to Nanaimo from Sidney, and will spend two other days of the week among the islands, maintaining a mail service, in addition to doing all other transportation business.

Capitalists from the marine provinces are figuring out the possibilities of establishing a trade between the coal fields of Nova Scotia and the iron ranges of Ontario. To carry iron ore from the Atik-Okan or Mattawin deposits, by way of Fort William or Port Arthur, becomes a project well worth consideration when the St. Lawrence canals have been deepened, and a waterway of 14 feet deep established. The vessels would not have to return light, because, being assured of full cargoes eastwards, they could probably afford to carry coal west to Montreal, Toronto, or even Lake Superior ports, at very low rates. The development of the Maritime Provinces coal trade is increasing rapidly. September coal shipments of the Dominion Coal Co. amounted to 196,000 tons, an increase of 32,745 tons over the same month last year. From March 1st to September 30th, this year, seven months, 1,031,500 tons, against 838,285 tons in the same period of last year; increase, 193,215 tons.

Mining Matters.

Campbell & McNabb, Douglas, are working a mica mine at Mt. St. Patrick, Renfrew county, Ont.

A valuable discovery of iron is reported on the property near Dog Lake, in the vicinity of Battersea, Ont.

The Canadian Copper Co., Sudbury, Ont., finds it almost impossible to secure men enough to carry on its work.

The Truro, N.S., Foundry and Machine Co. will have ready in a short time a 60-stamp mill for Waverly, N.S., gold mines.

The Copper Crown Mining Co. is going to extend the I.C.R. at Picton, N.S., to its smelter now under construction, the Minister of Railways having promised to pay the company for the outlay.

The Le Roi Mining Company recently ordered from the Jenckes Machine Company, three 100-h.p. boilers. These will be used to furnish the power for the 40-drill compressor plant, recently ordered by the company, and will be delivered early in March next.

John Cook, director of the Boerth Mining Co., stated recently that the mill at Ardoch, Ont., is running steadily and turning out gold in good quantities. The ore runs an average of $17 per ton, with considerable gold in the concentrates that will be treated later on.

One of the members of the staff of the Geological Survey, recently returned from field work in New Brunswick, states that alluvial deposits of gold have been discovered on the Serpentine, a branch of the Tobique, in Northumberland county, which seems to show splendid indications of the existence of gold in good paying quantities.

The Hall Mines, Ltd., Nelson, B.C., have just closed a contract with James D. Sword for a new steel wire tramway rope 50,000 feet in length. This rope is of a high grade steel, and has a breaking strain of nearly 70 tons, and weighs about 35 tons. It is to replace the old cable, and will be specially manufactured for the work required. This will be the fourth cable used at the mine.

Archibald Blue, of the Ontario Bureau of Mines, returned recently from a trip to the Michipicoten district; he said there was a great deal of mineral, and iron was the principal product. There has not been much development work done yet and there is much room for exploration. A branch of the Algoma Central Railway is being built from the Clergue iron mine to Michipicoten harbor. A branch will also be run to Dalton, to connect with the C. P. R. Surveying parties are going out now to prepare for the Algoma Central.

The Jenckes Machine Co., Sherbrooke, Que., shipped two car loads of mining machinery recently to the War Eagle Mining Co. It will be erected at once.

Railway Matters.

The C.P.R. has ordered ten more compound engines from the Kingston locomotive works.

The Canada Atlantic Railway is building a large number of 35-ton freight cars at its Ottawa shops.

The Shawenegan Falls branch of the Quebec & Lake St. John Railway has been open to traffic since October 23rd.

J. S. O'Dwyer, C.E., returned to Granby, Que., after exploring a route for a projected railway from the headwaters of the Skeena, to the headwaters of the Stickeen rivers, for the Dominion Government.

The Milwaukee Southwestern Railroad Co. announces that it proposes not only to build a line 200 miles long, extending southwest from Milwaukee, but that it intends to go into the lake and rail business, co-operating with the Canada Atlantic.

The Rainy River Railway is being pushed with great vigor by McKenzie & Mann's contractors. Between 5,000 and 6,000 men are at work on a section of 150 miles stretching from Stanley, on the Port Arthur, Duluth & Western Railway, southwesterly towards Rainy River, and next spring 10,000 men will probably be engaged in order to try and complete the line to secure a share of next year's northwest harvest.

The C.A.R. train that took the Government party to the opening of the Soulanges canal ran 81 miles in 76 minutes. Among those on board were, Hons. J. I. Tarte and Fielding; Collingwood Schrieber, Deputy Minister of Railways and Canals; L. K. Jones, secretary; J. R. Booth, E. J. Chamberlin, W. J. Poupore, M.P.; H. B. Spencer, of the Canadian Pacific Railway; E. Marceau, superintending engineer of the Quebec canals; R. B. Rogers, superintending engineer of the Trent canal; R. C. Douglas, of the Department of Railways and Canals; the representatives of the Montreal, Ottawa and Toronto papers, and others.

The Grand Trunk Railway has a surveying party at work making arrangements for improving the grades and double-tracking the line from Hamilton to Niagara Falls, Ont. This special work has been under consideration by the G. T. R. management for some time, and consequently the company of late has been putting in the stone abutments to bridges double width, so as to carry a double track when it would be required. It is expected that the contracts for widening the roadbed, tracklaying, etc., will be let during the winter, and the construction work commenced early next spring, and the double-tracking finished some time next summer. When done this work will complete a double track run from Toronto to Niagara Falls.

Personal.

R. R. Smith, superintendent of the Sherbrooke Street Railway, is ill with an attack of typhoid fever.

W. H. Randall has been appointed foreman of the meter and machine shops of the Toronto waterworks, Soho street.

Jas. Flemming, head of the foundry firm of James Flemming & Sons, St. John, N.B., died October 10th of apoplexy.

H. C. White, of Jenkins Bros., Boston, called on us during the past month. He reports good demand in Canada for this firm's goods.

Alex. Dyer has left Perth, Ont., for Birmingham, England, where he has secured employment with the Birmingham Tramway Co.

H. Orpen, for twenty four years foreman of the meter and machine shops of the Toronto waterworks, was presented with a gold ring by his friends in the department. Mr. Orpen resigned a short time ago.

J. Tees is now representing the Oliver typewriter in Toronto. This machine is built by the Linotype Co.

Chas. Potter, optical instrument maker, Toronto, died Nov. 3rd, aged 68 years, after many years' illness.

J. Laprairie, Montreal, has been appointed by the Canadian Pacific Railway Co., inspector for the car works at Perth, Ont.

E. Lafontaine, assistant engineer of the Department of Public Works, Ottawa, died in Vancouver, Oct. 10th, of typhoid fever.

The death of George A. Browne, traffic manager of the Richelieu and Ontario Navigation Company, took place at Atlantic City, October 12th. He was 40 years of age.

Mrs. Campbell, Guelph, Ont., has been given a verdict for $1,000 and of $500 each to two children in her suit against the Acton Tanning Company for the death of her husband.

Frank H. Pitcher, McGill University, Montreal, who has been demonstrator in physics for the past five years, has just been appointed engineer of the Montreal Water and Power Company.

Thos. Eversfield, engineer in charge of the heating and lighting plant of Toronto University buildings, has resigned, and Fred. Hanmer, formerly machinist at the Fensom Elevator Works, Toronto, has taken his place.

Jas. Gunn, Royal Military College, Kingston, son of Alexander Gunn, postmaster of Kingston, Ont., has received from the Imperial War Office an appointment in Egypt on the staff of the Government railways, under Lieut. Girouard.

T. G. Hazlitt, president and general manager of the Dickson Lumber Company, died at Peterborough, Ont., Oct. 12th. He was a native of county Armagh, Ireland, and came to Peterborough when a young man, and engaged in the lumbering business. In 1870 he became manager for the Dickson Lumber Company. He was 76 years old.

Joseph Smith, bridge foreman on the Canadian Pacific Railway on the North Bay division, while recently engaged in the work of repairing the trestle near Desbarats station, was struck by a passing train and knocked off the trestle, falling on his back, a distance of about fifty feet. He was removed to the hospital at North Bay, Ont., in a most critical condition.

C. N. Coburn, who has been looking after the engineering work in connection with double-tracking C.P.R. main lines in Ontario, has been appointed resident engineer of the C.P.R., at Smith's Falls, Ont. He supersedes A. K. Kirkpatrick, who, it will be remembered, was selected some time ago by the British Government to be engineer of the government railroads in Egypt.

The position of General Manager of the Canada Cycle and Motor Company, limited, has been offered to and accepted by Joseph N. Shenstone, the well-known secretary of the Massey-Harris Company, Ltd. He had much to do with the building up of the successful business of A. Harris, Son & Co., of Brantford, and since the formation of the Massey Harris Co., Ltd., has been a director and secretary of that company.

The remains of the late James A. MacMahon, railway contractor, son of the late Philip MacMahon, were interred in Dundas, Ont., October 16th. Mr. MacMahon was born in the town of Dundas 47 years ago, and his life has been spent in contracting. He had just been awarded a contract for 90 miles of railway construction in Eastern Canada, when he died. Amongst the large engineering works which deceased superintended may be mentioned the Government dry dock at Levis, Que., section 33 Welland Canal, several large contracts on the C.P.R., G.T.R., M.C.R., and the Canada Atlantic Railway bridge across the River St. Lawrence at Cotean Landing.

Ottmar Mergenthaler, the inventor of the linotype, died at Baltimore, Md., October 28th, of consumption. He was born in Wurtemburg, Germany, in 1854, and came to the United States penniless and friendless, when 18 years of age. He was employed by a Baltimore firm that was making some models of printing machines for James O. Clephane a Washington stenographer. He took a deep interest in the work, and for four years devoted his time to inventing a type setting machine of his own. After many experiments he made a complete change of system in 1880, and adopted the plan which resulted in the present linotype machine.

We regret that the senior member of the firm of the Brown & Sharpe Manufacturing Co., Lucian Sharpe, died at sea while returning from a trip to Germany. The deceased was born March 20, 1830. He worked on his father's farm in his youth and received a common school education. Leaving the farm, he served a five years' apprenticeship with Joseph Brown, and was admitted to a partnership in 1853. The firm of Brown & Sharpe was incorporated as the Brown & Sharpe Manufacturing Co. in 1868.

Iron and Steel.

The Montreal Rolling Mills Co., Montreal, is negotiating with Sydney, C.B., for encouragement to locate rolling mills in that town.

Work is being rushed on the branch line from the Kingston & Pembroke Ry. being built into the Caldwell mine at Calabogie, Ont.

The Rhodes, Curry Co., Ltd., Amherst, will build large work shops at Sydney, C.B. The company has already bought the land which is close to the junction of the Intercolonial and Louisburg Railways.

The Dominion Iron and Steel Co., Sydney, was advertising at the end of October for 250 men to mix concrete, 500 men on night work, 100 men to load scows, 100 horses and carts, and 50 carpenters.

The directors of the Hamilton Iron and Steel Company have decided to practically rebuild the furnaces and make other improvements at a cost of $50,000. When completed the furnaces will have a capacity of 250 tons of iron a day.

The Beaverton Express says that recently an experiment was made at Phoenix foundry in that town with peat made by the new compression system as a fuel for smelting iron. The Express reports the failure of the experiment, the fuel being too light.

The Nova Scotia Steel Co., New Glasgow, N.S., is building another smelting furnace. The large steel building will be extended some eighty feet to cover the new furnace and bring the steel traveling crane in connection with it. The furnace will produce 100 tons a day.

The work is progressing on the steel plant which is being built in Hamilton, Ont., near the smelting works; the construction is in charge of Clifford C. Smith, who represents the Wellman-Seaver Company, Cleveland. There will be two furnaces, each having a capacity of fifteen tons. The main building will be 144 feet long and 90 feet wide. The furnaces, which are open hearth, will use gas.

The discovery of iron on the line of the Rideau Canal in Frontenac and Leeds counties is no new thing, though considerable attention is being given to it. The old inhabitants in Lansdowne and neighboring townships still speak of Lyndhurst village by its old name of Furnace Falls, for there were iron works at that point nearly a century ago.

Application has been made for a charter of incorporation for the Canada Foundry Co., with a capital of $1,000,000. The company is composed of Messrs. E. B. Osler, M.P., W. R. Brock, W. D. Matthews, Wm. Hendrie of Hamilton, Fred. Nichols, T. W. Horn and W. H. Winslow of the Chicago firm of Winslow Bros. It is the intention to establish a foundry in Toronto, and later on another in the West, probably at Vancouver. All kinds of cast-iron work, including every branch of architectural work, will be turned out.

The concreting and brick work on the Dominion Iron and Steel Co.'s blast furnace No. 1 was finished October 6th. Work on the other furnaces was to be finished November 15th. McManus, Low & McManus, contractors, have been working day and night, an electric plant having been installed, but the cement for the concrete work ran out, and the work has gone behind. The contractors were supposed, when the ground was prepared, to average 800 yards of concrete per day. The area to be concreted is 25,000 yards. Two cars of cement were brought from Montreal, but the cost of transportation was too great, and so the work had to wait.

An important auction sale took place in Montreal, Nov. 1st, when the assets of the Londonderry Iron Co., Londonderry, N.S., were sold for the sum of $153,000 cash to interests represented by H. S. Holt, Montreal. The capital of the company, which was incorporated under a Dominion charter some years ago, was placed at a million dollars, divided into $400,000 preferred and $600,000 ordinary stock. The directors were: Lord Mount Stephen, Sir Chas. Tennant, Glasgow; A. S. McClelland, Glasgow; J. J. Greenshields, London, Eng.; A. T. Patterson, Montreal; Jno. Turnbull, Montreal, and R. McD. Patterson, Montreal. Some time since the company went into liquidation, and the property was placed on the market. The assets of the company, which have now been purchased, consist of about 30,000 acres of mineral land, town lots at Londonderry, N.S.; together with the plant and machinery now contained in the building and on the property of the company. The property known as the Chignecto colliery, and situated at Maccan, N.S., as well as all outstanding claims, unsold material, stores, goods, and any rights belonging to the company on the 25th of last September, are all included in the transaction.

F. H. Clergue, Sault Ste. Marie, who founded the great pulp industry at that place, is now organizing a $20,000,000 iron and timber and transportation company. This is the Ontario Lake Superior Company, which is being formed by the same capitalists who organized the Consolidated Lake Superior Company, with which it will be allied. The new company is to acquire the entire capital stock of the Algoma Commercial Co. and the Algoma Central Railway. It will thus, it is stated, acquire title to some 2,000 square miles of timber and mineral lands adjacent to the Canadian lands of the Consolidated Lake Superior Company. A railroad line is being built as part of the project, and 40 miles is to be in operation next year, from Michipicoten harbor, on Lake Superior, to two hematite iron mines, one of which is the Helen mine, owned by the Consolidated Lake Superior Company, in the Michipicoten range. The plan is eventually to extend the road 120 miles to connect with the Canadian Pacific at or near Misanabie. It is estimated that the company will handle during its first year 1,500,000 tons of ore for the Consolidated Lake Superior Company. Jas. Conmee, who has charge of the construction work on the railway, stated recently that 2,000 men were at present employed in connection with the company's projects. Half a million tons of iron ore were ready for shipment at the Helen mine, and there were ten millions in sight.

H. M. Whitney, at a reception tendered him at Sydney a couple of months ago, summed up the prospects contingent upon the establishment of the new iron works in these words: "I believe that the establishment of these iron works will be the means of introducing the town of Sydney to the length and breadth of the whole world. I cannot control my enthusiasm when I think of the future. The dormant energies of the country will be awakened. Here, right at our very doors, is the basic source of all prosperity. We know that on yonder spot all the elements that go to produce iron and steel, can be assembled cheaper than on any other spot on the face of the earth. We have limestone almost at our feet, immense coal fields right at hand, and magnificent iron areas within a few hours' sail from the centre of production. It has been demonstrated that Cape Breton coal is the best in the world for metallurgical purposes. The establishment of the iron and steel works signifies more than the works alone. Industries that depend upon the production of those metals are bound to follow. I have no doubt that there will be a gradual extension from one thing to another, and, unless I am greatly mistaken, before many years the production of this vast concern will stretch from the Atlantic to the Pacific, and the material manufactured be exhibited in all the marts of the world. To the province of Nova Scotia will be restored its old shipbuilding industry, for, when there is coalition in the manufacture of iron and steel, all industries depending upon these two metals must naturally prosper."

The iron mines of Belle Isle, near St. John's, Nfld., bought for $1,000,000 from the Nova Scotia Steel Co. by the Dominion Iron and Steel Co. are thus described by Elias Rogers, one of the directors of the company, in a recent issue of The Toronto Globe: The deposit is of peculiar formation and different from anything I have ever seen. The ore can be taken out more

cheaply than in any other mine that I know of, said Mr. Rogers. It is in the form of segregated cubes, which can be detached by the use of a crowbar, one man being able to pry off tons at a time. The only preparatory work necessary is to strip off from six inches to two feet of soil on the surface and by the insertion of a crowbar in the cracks which run vertically throughout the depth of the deposit the ore is pried off and falls into small cubes exactly in the condition we want it for smelting. All that remains to be done is to shovel the ore into the ore cars and ship it to the smelter. It is a high grade ore, the surface of the deposit at the workings has very much the appearance of a tiled floor. The seams are nearly horizontal, with a slight dip to the north. No. 3 seam, the seam at present being worked, is from eight to ten feet thick, and from where it outcrops to where it goes under the hill is perhaps 300 feet wide and three miles long. The ore is taken out so easily that no blasting is really necessary, although occasionally a cartridge may be put in several feet from the face of the working to loosen hundreds of tons at a time. This ore can be laid down at the smelter cheaper than is being done by any other mine in the world. The conditions for handling the ore could not be better. The natural formation of the island is perfect for the purpose of handling the ore at the least possible cost. The company from which we purchased had already constructed a first-class plant for handling the ore economically. There is a double track line running across the island and terminating at the loading pier. The cars are operated by means of an endless cable, to which they are gripped at distances of about fifty feet. The loaded cars going down grade help to operate the light cars going back to the mine by the gravity system. The cars are unloaded automatically into pockets, from which the ships are loaded. There is also a large pocket constructed in the rock, which will hold many thousand tons, from which the ore can be emptied by means of a conveyor in the bottom and running through to the pier. This will enable the company to continue mining and store the ore should there be any delay of vessels. The cost of the ore free on board vessels is about 30 cents per ton. The Dominion Iron and Steel Co. will handle 4,000 tons of this ore per day.

Electric Flashes.

C. H. Mitchell, C.E., and Guy Winn are preparing a report on a proposed power scheme at Bracebridge, Ont.

The Goderich Knitting Co., Goderich, Ont., has installed an 80-light incandescent plant, supplied by the Jones & Moore Electric Co.

J. Haynes, Brigden, Ont., has placed an order with the Jones & Moore Electric Co. for an incandescent lighting plant for his mill.

Clelland Bros., Meaford, Ont., are installing an electric light plant which they have bought from the Jones & Moore Electric Co., to light up the factory.

The Niagara Falls town council is considering the proposals of the Niagara Central Railway Company for the extension of that road and its conversion into an electric line.

The Niagara Falls Park and River Railway showed their appreciation of the work of the fire brigade at the power house fire by sending a cheque for $100 to the town council.

The Mack Machine Co., Belleville, Ont., is placing an incandescent plant in its works. The order for the dynamo was placed with the Jones & Moore Electric Co., Toronto.

There has been great delay caused in the power development works at Rugged Rapids, Ont., by the breaking away of the temporary dam. Supplies cannot be brought in till the temporary dam is in position. The contract calls for the completion of the works by December 1st.

Geo. Forbes, F.R.S., London, Eng., electrical expert; Clemens Henshell, New York, hydraulic engineer; Dr. Coleman Sellers, of Philadelphia, expert engineer and ex-president of the Niagara Falls Power Co., were recently at Niagara, in consultation with W. B. Rankine, secretary and treasurer of the Niagara Falls Power Co., regarding the development of power on the Canadian side.

The West Kootenay Light and Power Co. has ordered another 30-h.p. three-phase induction motor from the Canadian General Electric Co.

The Canadian General Electric Co. is furnishing the Montreal Street Railway Co. with 20 of its standard general electric 1,000 railway motors.

Bothwell, Ont., has made a considerable extension to the electric plant recently, the work having been carried out by the Canadian General Electric Co.

The Canadian General Electric Co. has received an order from the Summerside Electric Co., Summerside, P.E.I., for a standard 120 k.w. single-phase alternator.

E. W. Stickney, Esq., Newburgh, Ont., has decided to place an incandescent dynamo in his factory, the order for which has been given to the Jones & Moore Electric Co.

The Standard Chemical Co., Deseronto, Ont., has recently installed an electric lighting plant in its factories. The apparatus was supplied by the Canadian General Electric Co.

The Palmerston Carriage Co., Ltd., of Palmerston, Ont., has ordered from the Royal Electric Co. a complete lighting plant, consisting of a 100 light dynamo, switchboard and wiring.

Richardson & Sons, Bedford, N.S., have bought a complete electric lighting plant from the Royal Electric Co., for their factory. The Maritime Electric Co., of Halifax is installing it.

The corporation of Neepawa, Manitoba, has contracted with the Canadian General Electric Co. for a standard 75-k.w. monocycle alternator with switchboards, transformers and wiring supplies.

The Canadian General Electric Co. is installing two standard 45-k.w. multipolar generators for Tooke Bros., Montreal, together with switchboards, and three 15-h.p. direct current motors, and three 8-h.p. motors.

The Montreal Cotton Co., Valleyfield, Que., is continually increasing its power plant, and has just placed another order with the Canadian General Electric Co. for six 50-h.p. and one 100-h.p. induction motors.

Donnelly & Drum, Ottawa, Ont., have recently ordered from the Jones & Moore Electric Co., an incandescent dynamo. This firm have also received orders from three Quebec firms for incandescent dynamos during the past month.

A new electric company has been formed in Dutton, Ont., for the purpose of supplying light, heat and power to the corporation, merchants and residents of the town. The Canadian General Electric Co. is supplying all the electrical apparatus, transformers and wiring. The initial order is for a 30 k.w. single-phase alternator.

The town of Paris, Ont., is to have a second electric light company, W. H. Meldrum, with a number of local people, having formed a new company, and have purchased a complete outfit consisting of a Leonard-Ball engine and boilers, and from the Royal Electric Co., a complete "S.K.C." two-phase system, the dynamo having a capacity of 50 k.w.

The Trent River Paper Company, Frankfort, Ont., has placed an order with the Royal Electric Co. for a 40-k.w., S.K.C. two-phase generator with transformers and supplies. It is the intention of the paper company to not only light its own large premises, but also Frankford (one mile distant), Stirling (nine miles distant), and possibly Foxboro and Wooler (six miles distant). Work of excavation was commenced on the 27th of May last, and the fact that this month this company will be making paper is an evidence of the capability of the manager, Walter S. Miller.

Another large manufacturing business is being established at Sault Ste. Marie, Ont., which promises to reach vast proportions in the very near future. F. H. Clergue, president of the Lake Superior Power Co., has been instrumental in interesting American capital in the formation of the American Alkali Co., of which he is the vice-president. They purpose manufacturing caustic soda and other similar products under electrolytic processes, and the initial plant will require 1,000 h.p. for its operation. There has been placed an order with the Canadian General Electric Co. for three 300 h.p. specially designed generators to be direct connected to water wheels. The plant is expected to be in operation shortly.

The J. D. King Co. has decided to operate a portion of its Toronto factory by electricity, and has placed an order with the Jones & Moore Electric Co. for a 20-h.p. motor, and also a 6 h.p. for the elevator.

The Richmond Electric Co., Richmond, Que., has installed a second 75-k.w. "S.K.C." generator. It has also installed a number of two-phase motors from 5 to 15 h.p., that operate from the "S.K.C." system.

Since October 21st, Dundalk, Ont., has had its municipally owned electric light. The plant consists of Leonard engine and boilers, and an "S.K.C." 30-k.w. dynamo. The streets are lighted with incandescent lamps.

The steamer "Sardinian," which is to transport the Canadian contingent to South Africa, is well supplied with artificial illumination for "The Soldiers of the Queen." The Royal Electric Company, of Montreal, started to install a complete electric lighting equipment on this steamer, Saturday, October 21st, and turned over the plant, consisting of one 20 k.w. direct current generator with 325 lights installed, complete in operating condition, Thursday, October the 26th.

The following is a list of some of the motors sold by the Jones & Moore Electric Co., during the last month, which goes to show the growing popularity of their new type of machines: Littlejohn & Vaughan, Eakins & Ferris, H. F. Sharpe & Co., Atkinson Bros., Social Tea Co., two machines, making the third this year; Toronto Law Book Co., L. Sexsmith & Co., W. C. Hunt, McFarland, Gray & Southgate, two machines, making three this year; J. W. Dobson, Toronto Glass Co., M. & H. Peterson, L. M. Swawite, Toronto Show Case Co., Canadian Camera Co., all of Toronto; Queen's College, Kingston. Five machines have also been sent to Winnipeg, Man.

ACCIDENTS OF THE MONTH.

Edward S. Evans, who for eight years had charge of the shops of the Toronto Electric Light Co.'s works, died last month.

A. Ellis, an employee in the Fernie saw and planing mill, lost his life, October 27th, by falling on a circular saw. He was a native of Dobbington, Ont.

Water thrown on a fire in the Dominion Carbide Co.'s works in Ottawa, caused an explosion which wrecked the building, and seriously injured 15 men.

Nicholas Milburn was killed, October 13th, at Nanaimo, B.C., while working in Protection Island shaft, his face and head being crushed by a fall of coal.

Peter Wiese, Chandos, Ont., was killed in an explosion at a gold mine near Apsley, in North Peterboro'. Another miner, named Galbraith, had his eyes blown out and one hand and the fingers of the other hand blown off, which caused his death.

H. M. Innes and H. Doley, prospector, were drowned while prospecting for gold at Windermere, B.C. Two other miners named James Mills and Charles Crane were killed about the same time at Moyie Bay by a premature blast in Lake Shore mines.

A man named L. Giguere, aged 26, employed at Howard & Craig's sawmill, Beauce, Que., was at work running a bark peeling machine, when in stepping around it he slipped and was thrown against the frame with such force as to break his skull, and he died in a few minutes.

John Atkinson, Toronto, 32 years old, employed by the Great Northwestern Telegraph Co., as lineman, accompanied by James Grasby, St. Chrysostome, Que, 26 years old, a blacksmith by ocupation, were drowned in Little Wolf Pond, near Ogdensburg, N.Y., October 17th.

A freight train from Madawaska to Depot Harbor, Ont., on the Canada Atlantic Railway, ran into a landslide at Rock Lake station, October 18th, as a result of which fireman Homer B. Barney, Jericho, Vermont, was killed, and engineer Arthur Grogan, of Depot Harbor, injured.

G. A. Sampson, of the Aikenhead Hardware Co.'s staff, while assisting in the cutting off of a piece of cast steel in the iron store department of the firm, was struck in the wrist by a particle of the steel which embedded itself in the bone, and had to be located by X-rays before the surgeons could remove same. Mr. Sampson has been particularly unfortunate, and had scarcely recovered from a severe operation, and it came very hard on him in his rather weakly condition of health, especially as there was great danger for a time that he would lose his arm.

Wm. Partlo, an Ingersoll, Ont., miller, had a narrow escape from a horrible death a short time ago. He was superintending the remodelling of King's mill, when he fell down the wheel-hole, alighting on the pipe which goes to the wheel, and thence falling into the water below. The wheel was running at the time, and had he fallen a few inches either way he would have been ground to pieces by the machinery. He was partially stunned by the fall, but had sufficient strength left to raise himself out of the water, and he was rescued from his perilous position as quickly as possible and medical aid summoned. An examination revealed the fact that no bones were broken, but he sustained severe injuries to his back.

An accident occurred at the cement works, Napanee Mills, Ont., Oct. 25th, by which George Thompson, aged 18, lost his life. He and H. Sweet, a lad about his own age, were alone at the time. Sweet for some reason flung a cement sack over a shaft making over 200 revolutions per minute. According to Sweet's testimony, Thompson asked him how they would get the bag. Sweet replied, "It will have to stay there." Starting to go about his work, he noticed where the sun was shining on the opposite wall a shadow flying around. Turning his head he saw Thompson on the shaft. As soon as possible the machinery was stopped, and Thompson's lifeless body dropped to the floor, horribly mangled.

PETROLIA AND THE STANDARD OIL CO.

Editor CANADIAN ENGINEER :

Your article in a recent issue of your publication was a gross misrepresentation of the facts as they exist in and around the town of Petrolia, and while the information may have been furnished you from a source which you presumed was authentic, the intention of the originator of the ghost story was clearly to injure a prosperous town from some spiteful or selfish motive. True, Petrolia has lost its refining industry, and with it a certain percentage of population, but Petrolia was a good town when this department was located chiefly in London, and other centres outside the oil producing territory. The last twelve months have seen more improvements in the town than any equal period for some years. Granolithic sidewalks are being constructed extensively, and a great amount of building is being done, including business blocks and a very large and expensive church. Merchants report business as good as any season they have had, and collections prompt. The real prosperity of Petrolea has always depended on the production of crude oil, and to-day there are very few idle drilling rigs in the territory. As a matter of fact Petrolea was never asked to bonus the Bushnell Oil Co., and further, when the Bushnell Co. purchased the refining plant of Fairbank, Rogers & Co., it was well known that they were a branch of the Standard. The Canadian oil trade had nothing to fear from the Standard or any other corporation, so long as the Government could withstand the inducements that American capital was prepared to offer in return for certain favorable concessions, the chief of which was the privilege of importing oil into Canada in tank ships and tank cars, and certain minor changes in the tariff and inland revenue restrictions. The present Government gave the Americans all they asked, and the Standard then quietly and in a business like way purchased all the refineries in Petrolea, and closed them up, and located the entire refining industry at Sarnia, as they must necessarily have their works at a lake port to take advantage of the tank ship concessions. You will now find oil being carried in tank ships owned by the company to points all along the lakes and St. Lawrence routes, at a loss of thousands of dollars freight to American railways. As to what the Standard will pay producers for crude oil in the future one cannot say, but to-day they are paying $1.62 per barrel for what was selling at $1.40 per barrel when they assumed control. They can pay as high for crude as is required, as they have control of the market in the refined product, and can advance the price of refined oil in proportion to what they are paying for crude (or more so). Petrolia may have lost some industries, but it has always been so far ahead of other similar towns in the West, that even with these industries gone,

it is still one of the best towns to be found anywhere, and you will see no grass on the streets, and no lack of business and enterprise, in proof of which note the fact that they passed this week a bylaw with only eight dissenting votes, giving franchise to a company to put down deep wells for gas and install plant, etc., for heating and lighting.

November 4th, 1899. PETROLIAN.

SIR WM. MACDONALD'S GENEROSITY.

Prof. Robertson, Dominion Commissioner of Agriculture, delivered an address before the Ottawa Public School Board, November 2nd, on the subject of the introduction of manual training into Canadian schools. At the close of the address he said: Sir Wm. Macdonald offers to pay for the equipment required for educational manual training in one place in every province in the Dominion, and also to meet the expenses of qualified teachers and incidental maintenance for three years in all those places. In Ottawa, he offers to equip and maintain for three years as many centres as are required to give all the boys (about 1,000), between the ages of 9 and 14 in the Public schools an opportunity to receive this training. It is hoped that after a year or two an equally valuable course of practical instruction, suited for girls of the same ages, may somehow be provided, and doubtless nature studies in rural schools will be joined to them. In Ottawa the plan will, incidentally, provide for evening classes for those actually engaged in trades who need and want technical instruction. Sir William has authorized me to make a similar offer to the school authorities of Brockville, Ont., of Charlottetown and Summerside, P.E.I., of some places in the province of Quebec, of Truro, N.S., of Fredericton, of Winnipeg, Man., of Calgary, N.W.T., and of some place in British Columbia. To begin it on right educational lines a thoroughly trained and experienced teacher of high attainment will be brought at first from Scotland, England, or the United States. Next summer it is proposed to pay the expenses of several teachers from Canada in Great Britain and Sweden to take the course of training there, to see for themselves the educational systems and methods of those countries and to meet teachers and other education reformers in them. When those Canadian teachers return they will be as lights set on hill tops. The fire of their inspiration, information, and enthusiasm will spread. Such in brief outline is the proposal I have the supreme satisfaction and happiness of announcing. It must result in immediate, lasting, and far-reaching benefit to the boys of Canada. I am sure we all join in the earnest hope that Sir William C. Macdonald, the wisely patriotic and generous benefactor, may long live, gladdened by knowing that the children and the grown men and women of Canada rise up and call him blessed.

FIRES OF THE MONTH.

Oct. 4th. St. Matthew's church, North Sydney, C.B.; loss, $12,000.——Oct. 6th. Taylor Bros.' sawmill, near Port Elgin, N. B.; loss, $4,000; no insurance.——Oct. 6th. MacPhee & Meader's flour mill, Moulinette, Ont.; damages, $4,000; insurance, $1,500.——Oct. 9th. The buildings at Fort Lawrence, N.S., of the Chignecto Ship Railway, which were erected during the construction work.——Oct. 16th. N. Levinsen's sawmill, Lake Megantic, Que.——Oct. 18th. Elgin's tannery, London, Ont.——Oct. 18th. F. H. Manning's sawmill and barrel factory; loss, $5,000.——Oct. 19th. Murray's planing mill, Winnipeg; loss, $12,000; partly insured.——Oct. 19th. Grist and sawmill belonging to D. Purriston, near Richmond Corners, N.B.——Oct. 25. The Fulton Bros.' sawmill, Fingal, Ont.; loss $5,000; no insurance.——Oct. 27th. Kennedy Bros.' evaporating factory, Leamington, Ont., loss, $2,000.

—Granville C. Cunningham has been appointed manager of the Central Electric Railway, London, Eng.

—F. W. Draper, B.Sc., of Rolla, Missouri, has been appointed lecturer in Metallurgy in McGill University.

—We have received a pamphlet of 250 pages, being the Proceedings of the Illinois Society of Engineers and Surveyors, 1899, a report of the fourteenth annual meeting held at Champaign, Ill., in January last.

—The Marine Review, Cleveland, O., issued a special number in honor of the return of the United States Admiral from the Phillipines, which contains a large number of very fine pictures of the ships of the United States Navy.

Recently the Boston and Maine Railroad began to sprinkle oil over its tracks to lay the dust, having constructed two special cars for the purpose. About fifty miles of track was covered the first day, and the sprinkling will continue until the entire system in the vicinity of Boston at least is covered. The oil costs 8⅝ cents a gallon, and the cost of sprinkling per mile is $6,250. After three annual sprinklings the oil will remain effective for from three to four years. Hereafter, when renewal of ties are made, or other disturbance of the road bed is called for, the overturned earth will be oiled from huge tin pots with flattened nozzles.

WANTED—Draughtsman, thoroughly competent man. One accustomed to engine and saw mill work preferred. WATEROUS, Brantford.

WANTED—Young man familiar with installing and repairing electric recording meters. Give particulars of experience. Only hustlers and first-class penmen need apply. Advancement if satisfactory. Address "WATT," Canadian Engineer, Montreal.

FOR SALE

A good Water Power, 500 horse, situated one-half mile from railway, every facility for making siding to power. Address

I. D. THEUNISSON, Cookshire, Que.

Levis Waterworks.

Notice to Engineers.

"A by-law opening a competition for the preparation of plans and specifications to establish a system of waterworks, draining and electric lightning in the town of Levis" has been adopted at the meeting of the council held on the 16th October, 1899.

Moved by Mr. Councillor D. Laine, seconded by Mr. Councillor Joseph Carrier that the by-law opening a competition for the preparation of plans and specifications to establish a system of waterworks, draining and electric lighting in the town of Levis be adopted as follows, viz:

1. A competition is hereby opened to all competent persons, to prepare plans, specifications and estimates, for the establishment, execution, working and maintaining of a system of waterworks draining and electric lighting in the town of Levis.

2. The persons wishing to take part in the said competition can obtain the necessary information and particulars on inquiring at the Secretary Treasurer's office, at the city Hall, Levis.

3. The plans, specifications and estimates will have to be prepared so as to provide for the supply and wants of a population of twenty thousand souls at the rate of thirty gallons of water per head, every day.

4. The plans and tenders for the above mentioned purposes shall have to be deposited at the office of the corporation of Levis, on or before the first day of January next.

5. Those plans and tenders will then be submitted for examination to three competent persons chosen by the council, and the said persons shall report to the council within the delay fixed by the said council.

6. The council, nevertheless, will have right to choose and adopt whatever plans and tenders which it will deem most advantageous, and will not be held to accept those whose price will be the lowest or any of them.

7. A prize of $1000 will be awarded to the person whose plans, specifications and estimates shall have been declared the best by the three persons mentioned in article fifth of the present by-law; a prize of $500 to the person whose works will come in the second place.

8. These plans, specifications and estimates shall remain the property of the corporation of the town of Levis

FLAVIEN ROY, Secretary-Treasurer. J. EDMOND ROY, Mayor.

American Sewage Disposal Co. of Boston

89 STATE STREET, BOSTON, MASS. 60 BROADWAY, NEW YORK.

JOHN N. McCLINTOCK, A.M., C.E., President & General Manager

The Company is organized to design and construct sewers, and to build sewage disposal works (protected by patents), effecting any degree of purification required, under all climatic conditions. Circular sent on application.

We invite investigation, consultation and correspondence

SOUTH AFRICA, ITS PEOPLE AND TRADE.

CAUSES OF THE BOER WAR.

ARTICLE III.

To give an idea of all that has been suffered by the Uitlander population of the Transvaal would be impossible in so brief a sketch as this, but a few of the grievances may be stated. First stands the franchise. As already mentioned, when the internal independence of the country was granted in 1881, it was, of course, believed that all white races would be treated alike, and Kruger, in the most distinct manner, promised this. The franchise was at first to be given on a property qualification or upon one year's residence; but in order to cut off those who came in after the annexation, the Volksraad (Parliament) afterwards changed this to five years, and then when time passed by and the five years' citizens looked to the time of enfranchisement, the law was again amended so that a man had to be a constant resident in the country for fourteen years. When the conditions were looked into, it was seen that even when the fourteen years should have elapsed, the Uitlander would not get his vote, because the claim had to be based on the field cornet's records, and in nine cases out of ten, there were no records of the registration. In many cases the field cornet could not read or write, and in cases where he could, there was a temptation to neglect the duty. In a majority of cases he collected the taxes without making any returns, so that the omission of the names gave no record of the fraud, thus serving the double purpose of concealing his stealings and depriving the Uitlander of his vote. But even if this were honestly carried out, the Uitlander was further discouraged by the provision that he should first have to renounce allegiance to his own country, remaining a political eunuch for these fourteen years, and then when this time expired, he would have to get the recommendation of a majority of the burghers of his district (whom he knows to be hostile), and still after that his application is liable to the veto of the President and Executive. We see the pitfalls so artfully prepared, in order that a man would certainly fall in one if he escaped another. Can it be wondered at that the High Commissioner and the British Government wanted to make sure of the details of the recent proposals made by Kruger at and since the Bloemfontein conference? As President Kruger is a great reader of the Bible, it would be curious to know what he would have to say to the franchise provisions laid down in the 47th chapter of Ezekiel, verses 21 to 23? The Montreal "Witness," in pointing out this principle of Old Testament law, remarks that "the most curious thing in Boer legislation is that they should by special enactment exclude from participation in the land and liberty they enjoy, the very people to whom they are indebted for the Scriptures they prize so highly, and who, even before the Babylonian captivity, extended to the stranger, who came among them, the benefit of the ancient ordinances. This instance, however, only goes to confirm the estimate made of the Boers by Dr. Livingstone, who described them as narrow, stupid and cruel."

The Boer Government not only excludes both Jews and Roman Catholics from the franchise, but even from working in the civil service. If it is found out that a railway, post office, or other civil servant is a Jew or Catholic, he is quietly but speedily dismissed, and a Boer, Hollander, or German appointed to take his place. The Germans and Hollanders would, however, not be called in if it were not that very few Boers are sufficiently educated to fill these places.

By the trickery and breach of faith before described, the voting-power was kept, as before, in the hands of the Dutch burghers. As not one out of a thousand of the Boers of the rural districts had enough education to fill civic offices of responsibility, many Englishmen held public posts for a time after 1881, but one by one these were dismissed and Hollanders and Germans imported to take their places, until British subjects were almost as completely shut out from all share in the civic life of the country, as they were from political influence. One of the first fruits of this oligarchic rule was the system of plunder by concession. Each session of the Volksraad brought a horde of speculators, who purchased by bribery the sole right to manufacture or sell this or that article in the Transvaal. These mono-

polies, or "concessions," were secured chiefly by Hollanders and Germans, and hence, we see one mainspring of the active sympathy of Hollanders and Germans in the present contest, for between the fat salaries of the imported officials, and the dividends from the operation of the monopolies, a good stream of money has been flowing into Holland and Germany for some years past. When we consider this, and the extortions of the Netherlands Zuid Afrikan Railway Co., owned and managed by a group of Hollanders, and when we consider that by every device possible, British trade is hampered and Dutch and German imports favored, we see why the cause of the Boer should be so warmly espoused in Holland and by sections of the German press, even if race affinity were not a factor in the case. We may add to this the work of the Transvaal political agent in Europe, Dr. Leyds—a Dutch pocket edition of Talleyrand—who has been supplied with means to make the agency a nest of intrigue against Great Britain ever since his appointment. The Netherlands Railway Co. has practically controlled the finances and legislation of the State. It has been able to levy the outrageous freight rate, averaging 8½d., say 17 cents per ton per mile, as compared with 6 cents per ton per mile on the Cape and Natal railways, which themselves return a good dividend to their governments. Yet, when some of Kruger's own friends protested against these extortions, he said he considered this contract a matter of high policy, and would not even hear the subject discussed.

The art by which the combined Boer and Hollander legislators framed laws, which, while appearing to the outside world to be quite fair, yet could be made to work out to the particular disadvantage of the Uitlander, amounts to a positive genius. For instance, the school laws, while apparently giving a show to English children, are so worked as to school hours, etc., that in practice English children can neither get a chance to learn English or Dutch, while the school tax is so artfully fixed that the English parent, whose child is robbed of its chance of education, has to pay £7 against the Boers' £5. A law, to forcibly suppress all English private schools even, was proposed in the Volksraad, and only defeated by two votes. The school law is so beautifully arranged, in the case of Johannesburg, that the grand sum of £650 a year is spent on the children of Uitlanders, who have to pay nine-tenths of the £63,000 spent on education there. Then there is a tax of £20 recently levied on farms. Here the unsuspecting foreigner would see a tax levied on the Boer element entirely. Kruger cannot be so unfair after all. But look at it a little closer, and you will notice that farms on which the proprietor lives are exempt; look still closer and you see that it applies to farms owned by companies only. Now the Boer never buys stocks or bonds, and never goes into partnership, so you see it hits the Uitlander, who has bought up a Boer farm at five or ten times its agricultural value, on the chance of minerals being found on it. Another example of Boer "slimness": A poll-tax was recently introduced. It was to be levied on all male inhabitants, and there was no distinction or discrimination. Surely this was fair to all? Time answered the question in the same old way, when it became known that the tax of 18s. 6d. was faithfully collected from all Uitlanders, but not one Boer or Hollander has ever been made to pay. These are just a few samples of Krugerite equity.

We are familiar with the press law, by which Kruger has imprisoned and brought financial ruin on editors who have had the courage to run up against him. Of the same brand is the law giving it into the discretion of a policeman to break up a meeting, in the open air, of more than seven persons.

If the torture and degradation of thousands of Englishmen, Americans, Australians, and other peoples, accustomed to free institutions, were not in question, it would be amusing to those knowing the facts, to observe the injured innocence which glowed in the official despatches of the Boer Government right up to the time of the ultimatum. "If these people," said one of these despatches dealing with the petition of 40,000 Uitlanders made direct to the Queen, "instead of complaining to the British authorities had only come to this Government direct, their complaints would have had attention." What had they been doing all these years but complaining to a Government which treated their entreaties with scorn and contempt and only changed the chastisements by whips for those of scorpions? In 1893, a petition for the redress of grievances, signed by 13,000 Uitlanders, was presented to the Raad, and was received with a general laugh of derision. In 1894, another petition, praying for reforms, and signed by over 35,000 adult male inhabitants, was presented, and received more seriously, and it is due to some of the Dutch members that they made a stand for fair play; but the only response from Kruger, who moulded the Executive at his will, was new restrictions on the Uitlander's liberty, and new burdens on his industry. When the vote was taken on this petition, one of the Boer members was heard to say: "Nothing can settle this but fighting, and there is only one end to the fight. Kruger and his Hollanders have taken away our independence more surely than Shepstone ever did." It is only fair to say that many members of the Raad, who might be called progressive, by comparison, saw what Kruger's policy was leading to, and urged concessions to the Uitlander element. These were supported by a slowly-growing minority of burghers, who were almost as jealous of the Hollander faction as they were of British. But Kruger had his will; and when he found occasions arising where he could not carry his point by straight legislation, he went past the Volksraad and did it illegally, as head of the Executive. On several occasions he upset the decisions of the High Court, and ended by forcing the resignation of Chief Justice Kotze, who refused to prostitute the court, and make it the tool of the Executive. A more pliant man was put in his place, and Chief Justice Kotze was deposed without a pension or other allowance or support to his old age. A sample of the direct and easy way in which the Government overrode the decisions of the courts was furnished by the Doms case, among others. A man named Doms sued the State, but while the case was pending, the Government passed a resolution declaring that Doms had no right to sue! And so Doms was thrown out of court, lost his property, and is now a cab driver in Pretoria. When the Government wished to defeat the ends of justice, even in the High Court, all it had to do was to declare itself by resolution, and it was done whether the resolution conflicted with the

grondwet (constitution), or not. It is scarcely to be wondered at that the Uitlanders lost all hope of fair play when such things could be done.

(to be continued).

For The Canadian Engineer.

DESTRUCTIVE DISTILLATION OF SAWDUST.

A series of experiments have been made in Ottawa in October with a machine for the destructive distillation of sawdust, which is designed not only to get rid of the dust, but also to turn it to financial account. These runs were eminently satisfactory, exceeding even the expectation of those who knew most about the machine. Much has been written, and more said, about machines designed for the destructive distillation of sawdust and the products therefrom, but many difficulties have to be overcome before the desired object can be achieved. Sawdust offers so much resistance to the passage of heat through a mass of it that it is necessary to bring successive quantities of dust in contact with the heated plates, or to bring a mass successively into contact with the plates of the retort.

The machine referred to may be described as a cylindrical retort, to the ends of which are bolted flat castings, in the centre of which are holes to allow of the introduction of a short but large hollow shaft. On the outside of the end castings are stuffing boxes and glands to prevent gaseous and liquid matters escaping. Through the end openings pass the shafts, which just clear the end castings and then spread out to form four arm spiders which are bolted to a drum. In the centre of this drum and extending its entire length is a tube which is rigidly fastened to the end spiders.

In the spaces between the tube and the drum, and between the drum and the shell, are arranged plates which encircle respectively the tube and the drum, one forming a right hand and the other a left hand helix or conveyor. This arrangement ensures a continuous circulation of dust through the machine. The machine is fired in a way specially designed to maintain an even temperature throughout. No direct fire is allowed to come into contact with the shell. The machine is carried by lugs in an oven, the hot gases from which pass through the tube above referred to, thereby providing a large internal heating area ; from this tube the gases pass into the chimney

Charging is accomplished through an opening on the upper side of the machine, and the discharge is situated at the bottom or underside, and at one end, and is automatic. It is perhaps hardly necessary to state the nature of the products, but it may be interesting to some who may not have a knowledge of chemistry to know that destructive distillation is a process—broadly described as the decomposition by heat in a closed chamber, of a body the elements of which recombine, on cooling, to form compounds differing chemically and physically from the parent substance. When sawdust is submitted to this process it breaks up into bodies widely different from one another and from the parent substance. These bodies are principally pyroligneous acid or crude acetic acid, wood oils or wood creosote, tar, naphtha, or pyroxalic spirit, a large quantity of combustible gases, mainly carbon monoxide, and a residue of charcoal dust which is unequalled as a form of carbon for the manufacture of calcium carbide, showing as it does 98.95 per cent. carbon and only 1.05 per cent of ash. There are in addition to the above, smaller quantities of furfurol, acetone, methyl acetate, ammonia, etc., formed. The chemistry of these products is interesting and offers several alternatives in the methods of preparation for the market.

Although the machine was a proved success nearly a year ago it has been difficult to obtain reliable information in regard to it, as those interested were anxious to be disabused of any doubt as to the details and financial standing such machines would establish for themselves.

Patents have been granted in the U.S.A., Canada and nearly all industrial countries.

The machine has been tried in the utilization of other than mill refuse, but in this respect nothing will be stated till arrangements, mechanical and commercial, have been completed. This invention will be received by the public as a boon, effecting as it will a considerable, if not complete abatement of the sawdust nuisance. The interested parties have wisely avoided anything being printed until the machine had been proved in the presence of one of the largest lumbermen in the country.

The inventor of the machine, who at present desires to remain unknown, is also at work on a new method for the production of acetylene at a cheaper rate than is now possible, and hopes to be able to use the carbon from the machines whilst still hot.

A NEW ONTARIO.

It would appear that Ontario is about to come into her own. The courts have just sustained the Government in the matter of the manufacturing clause in the timber licenses, and in future the forests of Ontario will not be cut down solely to create United States millionaires and Michigan saw-mill cities. We will have saw mills of our own which will supply the United States consumer, and the millionaires will be cultivated to the north of the international boundary.

On the day that the decision of the court was handed down in the appeal case of the United States lumbermen, already referred to, the Hon. G. W. Ross, the new Premier of Ontario, announced a somewhat similar policy with regard to the nickel-copper bearing ores which, we have often pointed out in The Canadian Engineer, are one of the chief sources of wealth of Ontario and, indeed, of the Dominion of Canada. All mining licenses of nickel-bearing lands granted in future in Ontario will contain a clause prohibiting the export of the ore or matte, and permitting the export of refined nickel only. The Government would take power, also, if deemed expedient, to restrict the operations of the holders of existing licenses in the same way. It also appears that the Ontario Government has for over a year past been endeavoring to interest the Imperial Government in the use of nickel steel armour plate for the royal navy, and that there is a possibility of the Imperial Government assisting in the establishment of works for its production.

We do not wish to add ourselves to the stately procession of influential journals which, in a couple of days following Mr. Ross' announcement, each claimed that it had forced the Government to take what must, on all sides, be conceded as a splendidly advanced position. We are satisfied to point to our discussion of this subject, which has been widely quoted throughout the country. The Canadian Engineer wishes to offer its most hearty congratulations to the new Premier of Ontario for the work he is doing in developing our great country; we hope that we may soon be able to offer similar congratulations upon the settlement of the Niagara power question (which still needs to be settled), so that the greatest possible amount of power may be supplied to the largest number of

users and the greatest possible share of the profits be divided among the people of Ontario—not among the members of the Government.

The policy of the new Ontario Ministry on the nickel question is in fine contrast to that of the Dominion Government which—in spite of the protests of individuals of its own party—has played into the hands of the foreigu corporation which has held a monopoly of our nickle industry in a most questionable manner.

PROGRESS OF ACETYLENE LIGHTING.

A recent number of the Canadian Electrical News contained a table, attributed to a committee of the Canal dian Electrical Association, purporting to show the position of acetylene lighting in Canada. This table was compiled from replies received in response to circulars in which a series of questions was asked as to the number of generators installed, the number discontinued, the cause of accidents, etc. These circulars could only be sent to those who were known to have installed acetylene lighting plants. Unfortunately for statisticians a large number of people who receive such circulars never take the trouble to reply, and when this fact is taken into account, and the further fact that large numbers of business firms and private citizens have installed acetylene plants of which the compiler, could have known nothing, it will be evident that the table could be of very little value for statistical purposes. Indeed a footnote to this table states that it is "probably inaccurate as to the number of generators installed, the number in use, the capacity of light, the period of use etc." In other words, the compilers make the Canadian Electrical Association responsible for putting forward a table of figures which they admit to be inaccurate in every detail, including the "etceteras," which are supposed to comprehend the comments of those correspondents who reported. According to these tables there were installed in Canada last year 217 acetylene lighting plants, of which 62 had been thrown out, leaving 155 in use, and in 30 of these installations accidents were reported. Even if these returns were complete, a moment's reflection would show the inadequacy of the record. Every gas company and electric light company knows that a certain proportion of customers change their house and store lighting, throwing out one system and putting in another, or they discontinue their light by reason of removal to another place, but these changes, which are constantly going on, are no argument against either gas or electricity as an illuminant. Then as to accidents, the wonder is not that there were thirty accidents (the period of time in which these occurred is not stated), but that there were not three times that number. We must reflect that practically all these acetylene lighting plants were isolated ones; so that to make the comparison fair we have only to imagine that gas lighting had just been introduced when acetylene lighting was tried, and that each house was lighted by a separate generator as in the case of acetylene. Assuming that as little was known of the nature of gas as acetylene, we could then imagine how the record of accidents would compare.

The apparent purpose of these statistics was to show that acetylene was making no headway as an illuminant. That this conclusion is hardly justified may be deduced from the fact that the world's output of calcium carbide (the source of acetylene gas) has grown from a few thousand dollars annual value in 1895-6 to the value of $19,228,300 in 1898, the quantity of carbide being 282,380 tons. The countries principally producing this are the United States, Canada, Germany, France, Italy and England. As far as most countries are concerned, including Canada, the difficulty with the users of acetylene is that the supply of carbide has not kept up with the demand, and many people have had to give up actylene lighting simply because they cannot depend on getting the carbide. This deficiency may soon be remedied in Canada by the establishment of such works as those now being established by the Bronsons at Ottawa, which will be prepared to turn out 15 tons a day in the spring and will later on produce about 30 tons a day. The firm of A. Holland & Son, of Ottawa, who deal in calcium carbide, showed a representative of this journal orders from many foreign countries, some of them requiring a supply of several tons per month. These orders Mr. Holland has had to turn away because he could not guarantee the supply of carbide. The same difficulty is experienced at the Willson Carbide Works at Merritton. There is plenty of room in the industrial world for all three illuminants, and certainly the demand for calcium carbide for the production of acetylene gas is quite remarkable.

—F. G. Moon, Ottawa, an employee of the Post-Office Department, has invented another roller boat. A large working model has been built and a futile attempt was made a short time ago to make it roll. Like other roller boats, however, the trial of the model reveals a number of problems which the inventor had not taken into account. The roller principle of navigation has been tried in many places in Great Britain, Europe and the United States, but judging by its past records it is not likely to prove a success, except possibly for the navigation of sheltered rivers having a quiet current.

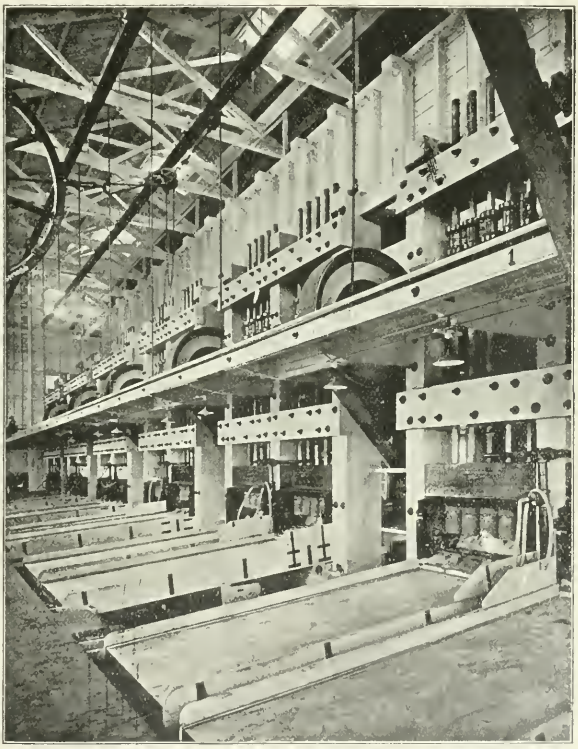
—The Bricklayers' and Masons' Union in Ottawa has passed a resolution condemning the proposed introduction of technical instruction into the public schools of Ontario. That such an act of folly should be succeeded the next week by a resolution of the executive committee of the Canadian Manufacturers' Association opposing the introduction into Canada of the metric system is almost enough to justify those amongst us whose croakings about the smallness of our industries and the hopelessness of their competition in the world's markets, at last have nearly been put to silence by the rattle of machinery in our overworked factories. The Manufacturers' Association has estimated that the introduction of the metric system would cost $2,000,000. With their all-sufficient wisdom these good people fail to offset this sum by the foreign trade of Canada, of which we stand in danger of losing a large part if we adhere to our present clumsy system. The metric system is simply applying to weights and measures the advantages we have in our monetary system. Would any Canadian discard our decimal system of money and go back to the "*old* Canadian currency," or the sterling system of coinage? As we realize the simplicity of the decimal system of money so we would see the immense gain in time and convenience in the adoption of the decimal or metric system of weights and measures. When even in conservative England a body like the Associated Chamber of Commerce, representing the crystallized opinion of the great commercial associations of the Kingdom, pronounces so emphatically on the necessity of this reform in order to save British foreign trade, we may realize that it is a change which must come. With ourselves it is only a question whether we or the United States shall be first in the field, for the latter country is now agitating for the change and has commenced an educational propaganda with that object. As to the Ottawa labor unions who wish their children to grow up without technical education in the schools, they should remember that when the steam

engine was introduced, it was their intellectual ancestors, was it not, who denounced and fought against that invention as a devilish machine which all pious laborers should destroy to save their children from starvation?

MILLING THE GOLD ORES OF THE WITWATERSRAND.*

The mill, in Witwatersrand practice, is but the first stage in the general metallurgical process, preparing the ore not only for its own treatment, amalgamation, but for the second step, the cyanide process, for it must be remembered that, but for the cyanide process, a very small percentage of the mines on the Rand would pay, and that the industry as a whole owes its salvation to this method of gold extraction. To examine the question of milling alone without considering the subsequent cyaniding of the tailings would produce a false impression, conveying the idea that the stamp practice on the Rand, in percentage of gold extracted, compares unfavorably with that of California or other places. The object is to get the greatest extraction at the least cost, by combining the two processes, the tendency being towards a high crushing capacity rather than a high extraction by amalgamation at the expense of crushing, relying on amalgamation for a fair percentage of the catch, and increasing the extraction by the subsequent cyanide treatment. While it is usual on the Rand to amalgamate in the batteries, less attention is paid to the practice than is common elsewhere. The easily amalgamated gold is caught on the outside plates, and the more refractory portion is treated by cyanide. Coarser crushing would be the rule, were it not necessary, in order to secure the best results in cyanide treatment, to have the ore crushed fine. The first mill, a battery of five stamps, at which any of the banket of the Witwatersrand was crushed, was erected in 1885 by H. W. & Fred. Struben, about ten miles from the place where Johannesburg now stands, for the purpose of working quartz reefs. The following year several samples of conglomerate were crushed, the highest yield being 8 dwts. per ton. H. W. Struben, in an interesting letter dated January 17, 1893, says: "We milled conglomerates from Vogelstruisfontein, both for ourselves and for others, at our private mill, long before anyone else had a mill."* The state mining engineer's report for 1896 gives the number of stamps for that year on the Witwatersrand at 4,291, and the number of tons crushed at 3,980,682, the yield being £5,346,527, or an average of 26.36 shillings per ton. Including treatment by cyanide and chlorination, the total yield was £7,781,845, or 38.05 shillings per ton, and the average duty per stamp per twenty-four hours 4.392 tons. Eight hundred and sixty stamps have been dropped since 1896.

There are few mills of less than 60 stamps on the Rand today and those of 100 and more are in the majority. The tendency of the newer mills, for large claim area, is toward 200 stamps, those of the Crown Deep, Rose Deep, Nourse Deep, Jumpers Deep, and Robinson Deep having this end in view, while the new mill at the Simmer & Jack Proprietary Mines, Ltd., has 280 stamps erected and in place, and the combination mill of the Angelo and Dreifontein Con. mining companies, now nearing completion, is to have 220. The older mines on the outcrop have mills with 60 to 160 stamps.



60-Stamp Mill, Nourse Deep.—Stamps Grouped by Tens.

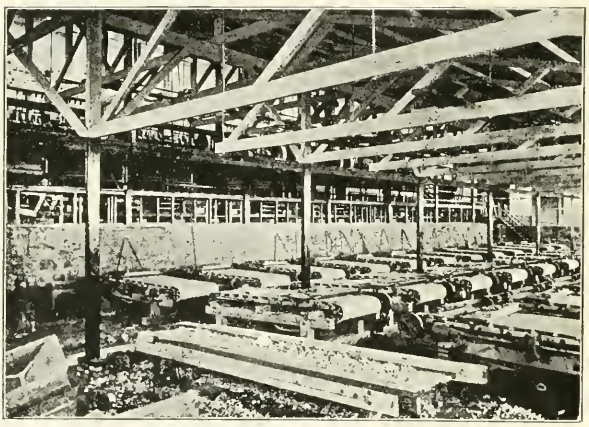
In the more recently constructed mills of the Rand the "banket" is delivered into the mill, after having been sorted and crushed, either at a central station or at stations at the shaft's mouth, and is fed from the ore-bins, by mechanical feeders, to the stamps, where, in the majority of the mills, a preliminary amalgamation takes place in the mortar box. The pulp flows over copper plates for further amalgamation, and in a few instances is delivered to frue vanners for concentration, the tailings going to the cyanide works; but the general practice of the Rand mills is to deliver the pulp direct from the amalgam plates to tailing wheels, or, sometimes, to pumps, to be elevated

*Abstracted from an article by H. H. Webb, and Pope Yeatman, in the Engineering Magazine.

**"Diamonds and Gold in South Africa," by T. Reunert.

to the height necessary for the requirements of the cyanide plant, a rough concentration by means of spitzluten being, as a rule, the first step preliminary to the cyanide treatment. Where frue vanners are employed, it is customary to use three for every five stamps, but, because of the heavy duty per stamp, they are often overloaded. The product from the vanners, being generally pyrites of high grade, is subjected to chlorination for the extraction of the gold. The mills are almost invariably placed near the mine rather than near the water supply. The building itself is framed with timber and covered with corrugated iron. Good foundations are put in, and the construction of the building is very strong. The timber is generally Oregon or pitch pine.

The ore bins are placed on strong masonry foundations, and are made of heavy timbers, well bolted together, the bottoms of the bins sloping towards the batteries at an angle of from 40° to 45°. In a few instances, as at the Simmer and Jack and the New Croesus, flat bottoms are used. Bottoms and sides are usually made of double thickness of 2-inch or 3-inch planks, with a lining of sheet iron. These bins hold from a day's run to four days' run. The feeders used are of the "Hendey Chal-



Arrangement of Frue Vanners in George Goch Mills.

lenge Ore Feeder" type, and are practically universal. There is no feeding by hand anywhere. The mortar boxes resemble the homestake pattern, the main differences being in the height of the feed opening and in the length and width of the boxes. Fraser and Chalmers and the Sandycroft foundry have supplied most of the batteries. As the stamp mills on the Rand are rather larger than the average, the mortar boxes, too, are larger and of greater thickness. At the issue the boxes vary between 11½ inches and 18 inches. Most of the mortars have heavy cast iron or steel linings in the front, back, and sides of the boxes, to ensure a longer life. Below the dies false bottoms of cast-iron are put in. Several thicknesses are often employed, to ensure uniformity of depth of discharge as the dies wear down. The mortars are placed on piles 12 to 15 feet in length, which rest on 1½ to 2 feet of concrete. The piles consist of heavy pine timber about 14½ inches square, and are bolted together firmly, both lengthwise and crosswise. The pile pits are excavated to hard rock, where possible. The walls of the excavation are built of heavy masonry or concrete, and the space between them and the mortar blocks is filled either with sand, or with tailings well rammed, or with concrete. Between the mortar block and mortar is placed a thick sheet of rubber or, occasionally, felt. The boxes are held down by eight bolts about 1½ inches in diameter, which at the lower ends are recessed into the wooden piles and are held by cotters. They are tightened by nuts on their upper ends. There is plenty of clear space about the batteries, and all bolts can be easily reached.

The screens are of well-woven iron or steel wire. The meshes range in number between 500 and 900 to the square inch, 900 being very common. The area of the holes ranges from .004 to .007 of a square inch. The life of the screen is very short, between two and three days on the average. The height of discharge in a battery is regulated by the use of chuck blocks as the dies wear down, or by having several sets of screens, which may be inserted from time to time. The width of the lower sides of these varies. The custom is to employ from two to three chuck blocks. There is a considerable variation in the height of the discharge. When amalgamation in the battery is considered an important feature, the discharge is raised; where rapid crushing is considered of more importance, a lower discharge is employed.

The first stamps employed on the Rand were considerably lighter than those favored at present. Stamps weighing from 750 to 850 pounds, the other parts being light in proportion, were used at first. In all the batteries now being erected, and in those that have been built within the last year and a half, the tendency is towards very heavy stamps, the weight varying between 1,100 and 1,250 pounds. The mills being erected under the supervision of the Rand Mines, Ltd., have stamps averaging about 1,150 pounds; those erected at the Simmer and Jack and at the Robinson Deep weigh nearly 1,200 pounds. Even with the old style of stamps, by adding extra tappets or putting in heavier heads, the weight has been increased, and, in consequence, the crushing capacity. According to the state mining engineer's report for 1896, the average weight of stamps was 973 pounds. In order to equalize the weight, it is the custom in some mills to use in one set of batteries heavy heads, and in another set lighter ones. New shoes are placed first in the second set, which, after being worn, are taken off and placed in the first. By this means the light heads always have the heavy shoes, and the heavy heads the partly worndown shoes.

Shoes are made of various varieties of steel, such as Chrome, Hadfield's Manganese, Firth's cast steel and forged steel, etc. They range in weight from 180 to 240 pounds. They are 8½ to 9 inches in diameter, and in height 9 to 12 inches. Heads and tappets are made of cast steel, the former weighing from 260 to 365 pounds and the latter from 106 to 130 pounds. Dies are 8½ to 9 inches in diameter and 6 inches high from the top of the 1 inch hexagonal bottom. They are made of Firth's, Hadfield's Manganese, or forged steel. Stems are tapered at both ends, and are made of fagoted iron. They range in weight from 350 to 475 pounds, and in diameter from 3¼ to 3¾ inches.

It is customary the world over to have five stamps to a battery. On the Rand two batteries are usually placed together, with a clear space of five to six feet between them and the next pair, each battery having its own cam shaft and separate driving wheel. In some cases one cam shaft and one driving-wheel serve for ten stamps. At the Simmer and Jack four batteries are placed consecutively, with two driving pulleys and two cam shafts. The plan of having one driving pulley for each five stamps is favored by the mill men, as the delays occasioned by necessary repairs affect a smaller number of stamps at a time. Cam shafts are made of fagoted iron, and range from 5 to 6½ inches in diameter.

Cams are made of cast steel, and vary somewhat in design

and in the manner in which they are attached to the shaft. The Blanton cam is deservedly popular; there are no keys, the cam being fastened to the shaft by means of a circular wedge, which is prevented from slipping by the short pins dropped into recesses in the cam shaft. This causes great saving of time in attaching cams and in replacing broken cams on the shafts. The George Goch has introduced for trial on one battery a cam which, instead of having a circular opening, has a decagon fitting on a cam shaft of the same section.

The drop of the stamps ranges from 7 to 9 inches, the average being about 8 inches. There is, perhaps, less variation in speed, this running from 92 to 104, the average being about 96. The order of drop is usually 1-3-5-2-4, although 1-4-2-5 3 and some others are employed.

The amount of water used in crushing ranges from 8 to 9 tons per ton of ore crushed. This does not mean that that amount of make-up water has to be supplied, as the water is used over and over again, the only loss being due to leakage, evaporation and absorption by the tailings. This loss, or make-up, is estimated at 25 per cent.

Apron copper plates are universally adopted. Inside the batteries both back plates and chuck plates are used, but the former are the most common. In some mills lip and splash plates are used. Apron plates are from 10 to 12 feet long, and from 4½ to 5 feet wide, and incline from 1 inch to 1¾ inches to the foot. Sometimes they are broken, but usually continuous. Back plates are from 7 to 11 inches wide, and chuck plates from 3 to 6 inches. The copper plate used is from ⅛ to 3-16 of an inch thick. They are rarely silver-plated, and, when a new mill starts up, considerable time elapses before the plates cease to absorb large amounts of gold.

One of the points of great difference in the Rand Mills is in the arrangement of the line shafts. These are either coupled directly to the mill engine or driven by rope-transmission. The latest mills erected by the Rand Mines, Ltd., employ direct coupling with the engine at one end. The new Simmer and Jack mill uses rope-transmission with two line shafts, one for each side of the mill. In the old Simmer and Jack mill, where the batteries were in line, the mill engine was placed in the middle, with fifty stamps on each side and with direct coupling. The Witwatersrand mill has the engine in the middle, but the line shaft is driven by rope-transmission. At the Geldenhuis Deep one line shaft is coupled directly, while the second is driven from the first by rope-transmission. Direct coupling works exceedingly well. Between the line shaft and the cam shaft various forms of belt tighteners are used. In many of the later mills patent clutch pulleys are employed, doing away with the tightening gear.

Very excellent power installations are the rule. In many instances the engine drives not only the mill itself, but also the tailings wheel, the electric light plant, the electric precipitation plant, the shops, and sometimes the crushers. Both vertical and horizontal engines are used, but the latter are in the majority. The usual type is the horizontal compound condensing engine with Corliss valves. To avoid delays an auxiliary engine is sometimes installed. This, of course, is a much cheaper engine than the main engine, and, while not compound condensing, is so made that it can be compounded if desired. The mills are well supplied with mercury traps made of wood, or, preferably, of iron, and have large and well-constructed launders with ample grades. One or more overhead crawls are used along each line of stamps for the rapid handling of the heavy parts of the batteries. The use of electricity for lighting is almost universal, and the old-fashioned, badly-lighted mill has become a thing of the past.

The clean-up room is well supplied with benches and the usual appliances for cleaning up. A pan, barrel, or batea run by machinery is used for the clean-up from the mortars. During operation the outside plates are rubbed every four hours, and the amalgam removed once a day. The general clean-up is made once a month. The percentage of extraction by amalgamation varies, but the average is from 55 to 65. Retorting and melting are not done in the mills, melting being done mainly in the assay office.

The amount of labor used is considerable, and, where one white man is employed in other parts of the world, at least one white and one native are employed on these fields. The labor employed at 100-stamp mill is as follows: 4 amalgamators per shift of 8 hours, 12; 1 engine driver per shift of 8 hours, 3; 1 blacksmith 9 hours shift, 1 carpenter 9 hours shift, 1 fitter 9 hours shift, 1 hoisting engineer 9 hours shift, 1 greaser; total whites, 20; 10 natives, assisting amalgamators, shift of 12 hours, 20; 10 natives assisting mechanics, 10 natives hoisting and dumping; total natives, 40.

Ore-Sorting Floor, Ferreiry Gold Mining Co

Where lifts of more than 40 feet are necessary, plunger pumps are commonly used. The latter have given good service where the proper arrangements have been employed to apply clear water to the plungers to prevent scouring. However, for lifts of less than 40 feet the tailings wheel is most satisfactory, requiring but little power and little or no attention. These wheels are patterned after those used at the concentration works of the Lake Superior copper mines. The temperature being so mild, there are no troubles due to freezing. Tailings wheels, launders, spitzkasten, etc., need no shelter.

The mill of the Simmer and Jack Proprietary Mines being the largest gold mill in existence, and a type of modern mill construction, a description of it is given here: Built on level ground, as are most of the mills on the Rand, the approach to the ore-bins is a raised earthen embankment having a 2½ per cent. grade, over which are drawn, by locomotives, trains made up of trucks of 20 tons' capacity each, which supply the mill with ore from the different shafts of the property, where sorting and crushing have already taken place. The mill building is 269 feet long by 100 feet wide, exclusive of the engine room and boiler

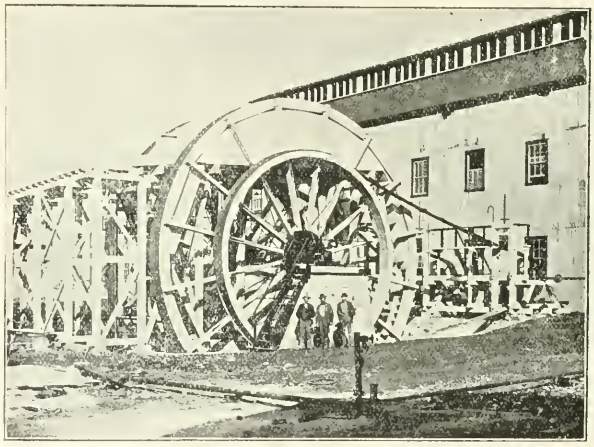
house, the frame being of wood covered with corrugated iron. The ore-bins are rectangular in cross section, the bottoms being flat, and have a capacity of 6,000 tons, or about four days' supply, with the full mill in operation.

The mortar blocks consist of eight karri wood piles bolted together, and the mortars are 4 feet 10 inches in length by 4 feet 8 inches in height, and are lined with steel. The sides are 1 inch in thickness, and the bottoms 9 inches. The feed opening is 3 feet 2 inches above the base, and has a width of 3½ inches for the full length of the box. The height of the discharge is 6¼ to 7¼ inches, and the screens, of 600-mesh steel wire, are 5¾ inches long by 10 inches wide, and have a life of three days, costing 54d. per ton of ore crushed. Amalgamation is done entirely on the outside plates or apron. This is a new departure at this property, as at the old mill inside amalgamation was also practised. The stamps are arranged in groups of twenty, ten being driven by each cam shaft, and weigh 1,200 pounds each. The drop is from 8 inches to 9 inches, and the order 1-5-3-2-4, the minimum of drops per minute being 95.

The cams are of cast steel, and have a sweep the outside diameter of which is 33½ inches. The cam shaft is of fagoted iron with a diameter of 6½ inches, and a length, over all, of 14 feet 3 inches. The cam pulley is of wood, having a diameter of 6 feet and a face of 17 inches. An overhead trolley is arranged under the cam platform for transporting shoes, dies, etc., to the mortar boxes. The mill has been running too short a time to enable an accurate estimate to be made of the consumption of iron and cost per ton of ore crushed. The battery tables have an effective surface 16 feet long by 4 feet 7½ inches wide, a fall of 1¾ inches per foot, and are covered with ⅛-inch sheet copper; they are constructed with one riffle 10 feet down from the mortar box end. A mercury trap is fixed at the end of each table. The pulp from the mortar boxes discharges on lip and splash plates before beginning the descent of the tables. There are two complete steel line shafts, one for each side of the mill, ranging from 10 inches in diameter at the engine end to 6 inches at the tail end. The pulleys for driving the cam shafts are 6 inches in diameter and 17 inches in face. The mill is driven by a compound tandem Corliss surface condensing engine, by Messrs. Yates and Thom, with cylinders 24 x 44 x 54, running at 75 revolutions, giving 900 i.h.p. The driving pulley is 21 feet in diameter, having grooves for 20 1¼ inch manilla ropes, leading off to a pulley 15 feet 6 inches in diameter on the near line shaft, the two line shafts then being connected with rope pulleys 15 feet 6 inches in diameter for 10 1½-inch manilla ropes. Rope tightening gears are used on both drives. There are five 300 h.p. Heine boilers with two 200 tube economizers and one steel chimney 100 feet high and 6½ feet square. The launders in the mill have a 4 per cent. grade, and deliver the tailings to three 50-feet tailings wheels, to be elevated for delivery to the cyanide works. Such a gold mill varies but slightly from the general type in California and the west of America. Distinctly different from this in one feature at least, and peculiar to the mill construction of the Rand Mines Company, Ltd., is that of the single line shaft coupled directly to the crank shaft of the driving engine—a style of mill first introduced in the Black Hills of Dakota. Those of this type on the Rand are of 200 stamps, or constructed for 200 stamps as an ultimate; for instance, the Crown Deep, Rose Deep, Nourse Deep, Jumpers Deep, etc. The ore is delivered to the mill from a central sorting and crushing station, by rope-haulage up an incline, to bins of about 2,700 tons' capacity, and fed by challenge feeders to the stamps.

The mortar boxes are Fraser and Chalmers' No. 102, the height from the base being 4 feet 10½ inches, and length over all 4 feet 10½ inches. The average thickness of sides is 1½ inches; of bottom under the dies, 9 inches. The box is lined with steel. The height of the feed-opening is 4 feet 4½ inches above the base, and the width is 4½ inches. The height of the discharge is 8 inches, and the size of the screen 700-mesh with a life of 36 hours. Inside amalgamation is practised.

The cost of mill construction on the Witwatersrand may be placed at from £400 to £500 per stamp, depending on the size and design of the mill.



New Style Tailings Wheel Simmer & Jack Mill.

THE TALL BUILDING UNDER TEST OF FIRE.*

BY H. DE B. PARSONS.

The modern "sky-scraper" presents many problems, but none more generally interesting than the question of its security against fire. Many imagine that, because iron and steel are incombustible (in the common acceptation of the word), buildings constructed of such material, together with bricks, cement and glass, may be classified as fire-proof. The construction of a building out of materials in themselves non-combustible does not produce a fire-proof structure. The ruin of the Quinsigamond mill, Worcester, Mass., caused by fire April 5, 1896, shows this. The building was erected on the independent plan, a steel frame supporting the floors and roof. The columns were of built-up steel, carrying floor beams of the same material. The window-boxes were of steel, and the walls were of brick built in between the frames so as to enclose the whole. Wood was used for the flooring on the "slow burning" plan. The building was gutted, and the columns and beams twisted into a tangled mass. Witnesses of this fire state that the columns began to yield from fifteen to twenty five minutes after the fire started, although the floors were not heavily loaded. Had this building been erected on the "slow burning" principle, it would have resisted the fire much longer. In this type of construction heavy wooden columns and girders are used, which retain for a considerable time, when subjected to fire, sufficient strength to carry their

*A paper prepared for the Engineering Magazine, and published in the reports of the British Fire Prevention Committee.

super-imposed loads, permitting the escape of the occupants, the saving of valuables, and the arrival of assistance. Such examples show that plans for all buildings in crowded districts should be entrusted only to the best of designers. The design would be much simplified if there were no fear of fire. What constitutes a "fire-proof" structure? The term "fire-proof" has become generic, and is in many instances a misnomer. In its usual sense it is used to designate a certain style of modern structure that has become very popular. Structures of this type rely for their stability, support, and fire-resisting properties, on the steel and iron skeleton frame and on the other non-combustible materials used.

It has been repeatedly proven that metal construction cannot withstand fire, unless well guarded. No matter how "fire-proof" a building may be, it will be ruined, if sufficient combustible material is stored within to create a hot fire lasting for a considerable time. Manufacturers have produced many forms of fire-proofing protection, and have striven to obtain something that will not burn. Architects and engineers have given too much attention to the substance of which the fire-proofing has been made, and not enough to its proper application. It is, however, fortunate that the present tendency is in the direction of protecting the metal skeleton as a primary object, since upon it the self-sustaining properties of the whole structure depend. It should be a secondary object to so sub-divide the floors as to confine the fire.

Without injuring the usefulness or the efficiency of the building, the amount of combustible material now used could, by careful planning, be reduced. In the ordinary American office building wood-work is commonly used to a much larger extent than generally supposed. Taking as an instance a ten-story building of recent fire-proof construction, the wood-work in the floors, panels, bases, chair-rails, doors, window frames, and general trim amounted to about two pounds for each cubic foot of contents. This estimate did not include the furniture or movable office-fittings. The total weight of wood was about 1,200,000 pounds, or as much as the weight of the iron frame. In some of the largest and newest buildings the weight of wood-work has been reduced, but there are many in the sky-scraping class in which the wood considerably exceeds the weight of metal. A number of these tall structures are more vulnerable from fire without than from fire within. The design is often such as to render it difficult for a fire to obtain headway within the building before its discovery, while the same building would be most susceptible to damage if a fire should occur in the immediate vicinity. Designers fail, as a rule, to give due weight to the value of these external hazards. A good example of this is seen in the damage done to the Manhattan Savings Institution building, New York, through a fire on the opposite side of the street. The girders in this building were unprotected, and, failing, permitted the floors to fall.

Some three years ago a joint committee, representing the insurance, architectural and engineering interests, made some elaborate tests of the effect of fire on full-sized metal columns, finding that such columns failed when heated to a faint red color, representing a temperature of about 1,200 degrees F. The steel columns buckled at the centre, while the cast-iron ones bent, snapping, if not relieved of their load, when the amount of deflection began to exceed the diameter. The time required to cause destruction varied from 20 minutes to 2 hours, according to the character of the test—a result which agrees very closely with the failure in the Worcester mill. The cast-iron columns were heated to more than 1,100 degrees F., and were then suddenly cooled by means of a fire stream. No injurious effect was produced, beyond the cracking of the furnace brick-work. The result of our knowledge, based on actual experience and on experiment, is that iron and steel cannot support a load when heated to a faint red. The metal must be protected. It will not suffice to have simply a non-combustible protecting material; the material must be of such a character that it cannot be disintegrated or dislodged either by water or by expansion. The covering must be so fastened as to remain in place, and such fastening is best accomplished by self-bonding, and not by wiring or similar artificial means. The desire of the owner and real estate agent to obtain light for halls at the expense of safety, and to economize space by placing the stairs and elevators in the same well, should be strongly restrained.

It has become possible to consider from a practical standpoint this important subject of a fire-proof building versus fire, by taking as an illustration a recent conflagration in New York city. The building in this instance was no doubt much favored in the assistance rendered by one of the most efficient fire departments in the country. On the night of December 4, 1898, a fire occurred in a five-story ordinary brick and wood building, situated on the southwest corner of Broadway and Warren street, occupied by Rogers, Peet & Co., as a retail clothing store. Adjacent to this, on Warren street, was another, but smaller building of similar design, used as an annex. On the south was the comparatively new Home Life Insurance Building, and, next to it, that of the Postal Telegraph Company. The Home Life Building has sixteen stories, and the floor plan is arranged with a light shaft in the middle of the north side. Along this light shaft are the elevators, and next to them is the staircase. The side and rear walls are of brick, while the front is of marble, built solid from the foundations. The building, with the exception of the front wall, is constructed on a skeleton frame-work of steel. The walls are lined with 2-inch porous terra cotta furring. The floor arches consist of 12-inch and 9-inch hollow, hard-burned, terra cotta blocks, the skew-backs covering with their soffit extensions the lower flanges of the steel floor beams. The columns are of steel, built up, H sections, and covered with 2-inch porous terra cotta furring blocks. The girders are protected on their sides with the same terra cotta blocks, while their soffits are covered with wire lath and plaster. The upper chords of all the girders, except one on the sixteenth floor, are buried in the floors. The principal partitions are made of 4-inch porous terra cotta blocks without metal supports. Many of these partitions are not continuous to the ceiling, being finished off with large plain glass transoms set in wood framing. All the windows were of glass set in wood sashes and window boxes. There are no shutters. The finish of the office floors consists of a wooden floor laid on sleepers placed across the floor beams, and not buried in ashes or cement. The walls and ceilings are plastered. There is a varnished base, chair-rail, window, door, and transom trim. Within an hour after the fire started, a strong northerly to northeasterly gale was driving the flames from the Rogers-Peet building against the walls of the Home Life building and into the light well, which acted as a chimney. The fire entered the unprotected windows of the eight upper floors, and found inside a natural draft through the elevator openings. The result was the total destruction of the contents of the upper eight floors, and the saving of the Postal building by its equally tall neighbor. As a fire stop, the Home Life building certainly succeeded admirably, for, had it not been there, it is fearful to contemplate what might have resulted during a gale of almost hurricane force. Such buildings are not, however, erected or designed as fire stops, and can be so treated only incidentally.

The vagaries of the flames were as peculiar as ever. In one room where the contents were destroyed a waste-paper basket remained, and in another a towel still hung on a rack unscorched, although the room was totally wrecked. The lower eight stories escaped the fire, but suffered from water. There was a total destruction of the finish of the various floors, nothing being left except the absolute fire-proof material. The plaster work, although not combustible, was absolutely destroyed, and in all of the rooms, from the ninth floor up, there is hardly any plaster left on the walls. The wire lathing used over the pipe chases in the walls and over the various irregularities in the building appears not to have stood the attack of the flames. This may have been due partly to the manner in which it was fastened, but more probably to the fact that the metal expanded sufficiently to throw off the plastering, which has no flexibility. The wood-work used in the finish of the building was not preserved in any of the rooms reached by the fire, except in a few in the rear of the building. In some of these a part of the office furniture still remained, although badly wrecked. In one room on the fifteenth floor a tall wall bookcase still stood. The book-shelves were protected by the closely-fitting books placed upon them, while the books were damaged beyond use. Had these shelves, however, been in the front of the building, they, no doubt, would have been destroyed, as there the fire appears to have been fiercest, probably because there were window openings on the north wall of the east wing. Those

partitions which were cut for the purpose of inserting large transom windows near the ceiling suffered most. The glass in these windows no doubt broke, and permitted the flames to spread from room to room, thus removing the value of these partitions as fire stops. The main metallic frame-work was but slightly damaged. A large proportion of the injury was done by the firemen and the building inspectors, and cannot be attributed to the flames.

The destruction of the wooden flooring throughout the upper stories was largely due to the considerable air-space between the wood and the flat floor arches. This space should not have existed; had it been filled, the floors would have stood much longer. The effect of using other material than wood for flooring is plainly illustrated in the various halls, which were subjected to an enormous heat. The flooring of the halls was made of mosaic blocks. These blocks retained their position, and the floors were practically uninjured, although there is nothing left of the wood flooring in the rooms adjacent. The amount of wood used was no doubt excessive, viewed from the standpoint of best practice. Wood-work will not stand a hot fire, even when embedded in the walls. Other material can be adopted for chair-rails, bases, and panellings without injuring the appearance or the utility of a building.

The fire had no difficulty in entering the building, as all the windows on the north side were unprotected. The building might have been saved, had these windows been equipped with iron shutters, and had wired glass been used in a metallic frame. This wired glass will resist an immense amount of heat, and, although it breaks in time, the pieces remain in place. Metal frames fitted with wired glass could have been used to advantage in all the partition transoms. Such an arrangement would have given nearly as much light throughout the building, and would have been a better fire stop. The flames, on entering the elevator shaft, appear to have gone at once to the sixteenth floor as the destruction of the trellis work and iron framing around the elevator doors is greatest at that point. Owing to its position, the staircase was rendered useless as soon as the fire obtained considerable headway, although, as constructed, it was partially protected by the division wall between it and the elevator shaft. The stairs remained intact, so that they could be used as soon as the fire was extinguished. The front of the building was built of solid marble, the poorer pieces obtained from the quarry being used as backing. The facade was relieved with balconies and other ornamentations, and a row of columns supporting arches made a finish to the fifteenth and sixteenth floors. The fire totally wrecked the marble, wherever it was exposed. Marble and granite have but little fire resisting power, and it seems useless to adopt them in a building intended to be fire proof. They are so susceptible to heat as to be liable to injury by fires occurring at a considerable distance. A greater heat than that to which the marble was exposed was endured by the brick work on the north face, and by the brick work up the light well. The chief visible damage to this was the cracks caused by the expansion and contraction of the braces reaching across the light well and stiffening the two wings. Taken as a whole, the building resisted the action of fire remarkably well. Within a week many of the offices on the lower floors were again in use. The steel structure, with the exception of a few portions, such as the girder mentioned above, can remain without repairs. The damage to the floors was slight; and, although the total wreck was great, it was practically limited to the trim and contents of the various rooms on the upper nine floors. The front wall, however, was ruined from the eighth story up. No doubt the destruction would have been less, had as much care and energy been bestowed upon the details of construction and finish as were given to the main frame-work and general plan. The building contained its own fire apparatus, but it is reported that this failed early in the evening. Owing to the height of the building, it was impossible for the fire department to reach the seat of the conflagration. The fire, therefore, had great liberty, although it was effectually prevented from spreading to the lower floors.

Here was a building which was, in the ordinary sense, a fireproof structure, and yet it was damaged. Again arises the question: "What constitutes a fire-proof building?" It is evident that, if fire is brought into contact with articles that are combustible, those articles will be burned; and that, if the fire must be confined to one specific space, that space must be enclosed effectually by absolutely fire-resisting material, which must be so constructed as to form practically a furnace. Such construction is not applicable to a building used for ordinary purposes. The next step, then, is to so arrange the structure that, when fire takes place, no damage shall be done to the main members, whether those members be of masonry, iron or steel. In all our cage constructions the members needing the greatest protection are the columns, girders and beams. It is not difficult to protect these members effectually, provided the owner and the designer are willing not only to spend the proper amount of money and care, but to give up the requisite floor-space. This part of the problem was fully illustrated in the Home Life building, as the only members seriously injured were the unprotected parts of the metal structure. It is axiomatic to state that floors should be separated from each other, so as to confine the flames. This is a condition difficult to attain, as perforations must be made for both stairs and elevators. These openings are generally placed so as to take a minimum of floor-space, and thus render a maximum area available for income-earning purposes. Nearly every intending builder examines the various buildings, estimates the amount of space devoted to public use, and concludes that the best building is the one that has given up the least percentage of space. While this effort is commendable from the purely income earning standpoint, it not only has the effect of rendering the design dangerous to life and property, but makes it almost an impossibility to so design a building that it shall be fire proof. In any building there must be, and always will be, an amount of combustible matter that cannot well be reduced. It is, therefore, essential that the least amount of combustible material shall be used in construction. In those

New Windsor St. Station of C.P.R. at Montreal.

The wing on the left has been hitherto the Main Building. The frontage of the extended structure, on Osborne Street, is 325 feet. The floor space is increased from 50,404 square feet to 102,131 square feet.

rooms in the Home Life building which suffered the least damage, it was clearly shown that the combustible materials placed near the ceiling were destroyed more rapidly and more completely than those nearer the floor. The heat and flames naturally follow the ceiling, and the ordinary fire-proof partitions in which there are large transom windows are thus rendered useless as fire stops. The use of transoms in these partitions is no doubt a necessity, but they should not be fitted with material so friable as ordinary glass. Even in a fire-proof building dependence must be had upon human aid. When the building is tall, it towers beyond the reach of the fire department, and reliance must be placed upon other means. A fire in the lower stories is easily accessible; the conditions to be most dreaded are those of a fire in the upper stories.

Many modern tall buildings are designed with their own pumping plant to supply a roof tank for fire and other purposes, and are equipped with a large stand pipe from six to eight inches in diameter, which is siamesed on every floor for hose connections. This stand-pipe is also arranged with a check valve and with siamesed branches at the foot, so that fire engines can be attached, in case of the disability of the self-contained plant. It is well so to arrange the stand-pipe that the engines can also operate in conjunction with pumps in the building.

In many cities which maintain a system of fire boats there are laid underground pipe lines of large diameter. As these fire boats are equipped with pumping apparatus far exceeding the power of the largest land engines, they are able to force water under heavy pressures to long distances, provided the mains are made of sufficient area to minimize the friction losses. This system, operated in connection with the building stand-pipe, would materially assist the firemen.

The question naturally arises whether it pays the owner to make a building thoroughly fire-proof. Unfortunately there are many who build for the specific object of obtaining the greatest income from a minimum outlay, and the effort to save on the first cost is so great as to render their judgment valueless as to what should or should not be done. Tall buildings of cheap construction are a menace not only to the owner and tenants, but to the community. Too much stress cannot be laid upon the great aid that could be rendered, but unfortunately is not, by the insurance companies. If they would be more strict in the classification of their risks, improvement would immediately follow. Are these tall buildings really good investments? The increase in height appreciates the value of the land, but how much of this appreciation is offset by the depreciation of the building, by the extra cost of maintenance, insurance, repairs, taxes, interest, etc.? In other words, would not a smaller building pay a greater percentage upon the money invested, if a careful and accurate balance sheet should be drawn up? Following the same line of thought, there has arisen the question whether the height of buildings should not be limited by law? If every building could be constructed upon utopian principles, probably there would be no reason to limit the height other than one of a purely aesthetic character. As such a state of affairs does not, and probably never will, exist, and as so-called fire-proof buildings are liable to be constructed, it seems that some form of proper restriction would be advantageous to the community.

THE SMOKE NUISANCE.

Montreal is taking active steps towards the abatement of the smoke nuisance. Complaints from people living within a considerable radius of a factory or public building where soft coal is used, are frequent. The smoke is a great inconvenience, as doors or windows cannot be opened for purposes of ventilation; clothes hung out on wash days are ruined; the houses themselves rapidly become dingy in appearance, and the smoke finds a lodging on the roofs of the buildings, lies there until rain comes and washes the combination of soot and water down the walls, leaving them streaky, and indelibly defacing the architectural beauties of many fine buildings. Manufacturers are consequently put to much expense and great annoyance in trying to do business, and at the same time keep the peace with their residential neighbors. Many devices are on the market which effectually burn the smoke and save the coal when properly handled, but what is needed is a smoke consumer, which can do the work, and yet be within the reach of all. The makers of the Redpath-Reid patent smoke consumer claim that with their machine the best results are achieved.

NEWFOUNDLAND'S MINERAL WEALTH.

Belle Isle is reached by a twelve-mile drive from St. John's to Portugal Cove, on the first road ever built in the colony, some 70 years ago, writes J. Ewan in special correspondence to the Toronto Globe. The Cove lies opposite the southern shore of the island, but between them there runs about as tricky a piece of water as there is around the coast of Newfoundland. The island presents a perfect precipice to the sea at all save two or three points. It is eight miles long by two in width, and contains farming lands that are superior to anything on the adjoining mainland.

The Nova Scotia Steel Company was the first to begin the extraction of ore at Belle Island. The idea appears to have been to get enough ore for its own use, and the company went to work in a tentative way. It was fortunate enough to secure the management of R. E. Chambers, a Nova Scotia man of wide experience and resourcefulness. As the original plans did not contemplate the getting out of a great deal of ore, it is remarkable that they were so laid as to be adaptable to a much larger output when the demand for the ore ran away beyond the original modest estimates. Work had not got well started before it was found that besides supplying its own iron and steel works in Nova Scotia, the company had the opportunity of selling the ore to German furnaces. It took all the orders of this kind that came, and latterly orders came from the United States, so that during the last year closed, instead of the few thousand tons that would have been sufficient for the company's own purpose, it will have shipped out 300,000 tons.

The side of the island on which the ore lies fronts a sea in which vessels would have no protection in a storm. On the other side facing the mainland, there was a slight recess in the bold shores where a vessel could lie at a wharf in comparative safety. The choice of this side for shipping necessitated the building of a cable tramway across the width of the island. It is a double track, two feet gauge, an inch steel cable passing around wheels at each end and down the centre of tracks. On to this moving cable the steel cars, containing each a ton and a third of ore, are attached as soon as filled at the mine, and they start their journey across the island to the pier. The cars are strung along the cable not more than ten or fifteen yards apart, and one of the sights of the island is this procession of little vans, those on the west track full and those on the east track empty, proceeding at a stately pace across the country. On arrival at the pier each is in turn automatically dumped into enormous pockets and starts in the procession of "empties" back to the mine to be filled again. The steamers are loaded from the pockets, and the facility with which this is done may be gathered from the fact that a steamer has been loaded at the pier with 6,400 tons of iron ore in four hours and a half.

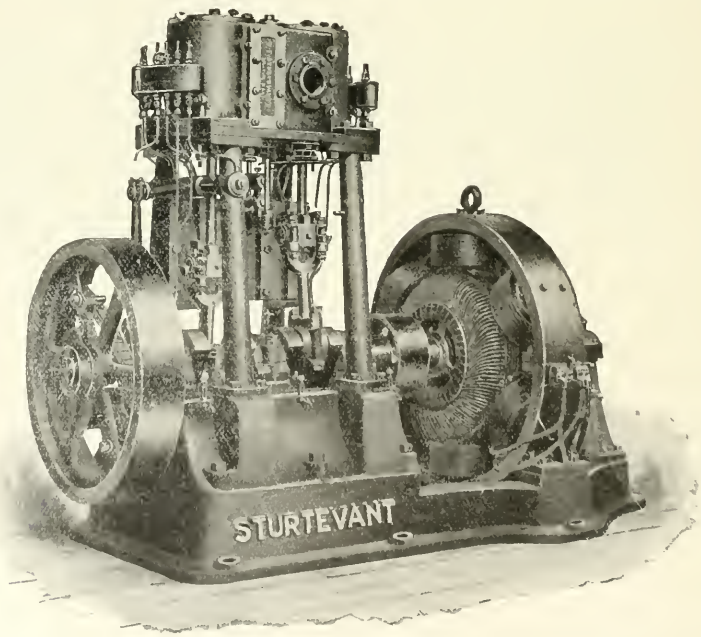
The pay roll of the Nova Scotia Steel Company on Belle Isle in October was $24,000, and when the other company gets to work next year that sum will be at least doubled. The Nova Scotia Company is by no means through with the island. It still retains the upper bed, and is at the present moment building a duplicate of the first pier at a sheltered spot on the coast to the west. The road-bed for a tramway is already laid across the island, and it is quite likely that its operations next year will be quite as great as this year. The statement is made that the Whitney Company will get out 500,000 tons of ore a year, and the construction of a second tramway, making the third across the island, seems to indicate that they contemplate a greater output than their predecessors. "What I like about Belle Isle," says Mr. Ewan, "and the other effects that flow from it, is their actuality. Here one is not stuffed with talk, but feasts his eyes on facts—on thousands of men at work, at vast vessels obeying their mistress, commerce, and ingenious machinery working the will of man. The whole arithmetic of the situation is that this ore can be laid down at Sydney at a cost of probably less than 50 cents a ton."

Not far from Belle Island is Bai de Verde, where an English company, the Newfoundland Iron Ore Co., has been at work for

a considerable time at the preliminaries to mining an iron deposit there. The main shaft is at Worthington, near Lower Island Cove. The ore is a red hematite and is said to be of a higher grade than that in Belle Isand. It is said that 500,000 tons are in sight. The company has spent a large amount of money, but as yet has extracted no ore. The Tilt Cove Copper Mine has been operated since 1868, and last year was perhaps its most profitable year. Every once in a while reports have been circulated that it was at the end of its tether, but it has always come up smiling, and let us hope that it will always do so. About 200 men are employed at the mine. Petroleum has been found at Parson's Pond, at St. Paul's and at Port au Port, but the value of the find has not been demonstrated. There are fine slate deposits at Britannia Cove, Trinity Bay, the product being it is claimed better than any in the United States. The quarry has been sold very recently to Harvey & Co., an enterprising firm in St. John's, for the sum of $25,000. The facilities for shipment are excellent, and England is the market which the owners have in view. A gypsum deposit on St. George's Bay has been leased by a company at a rental of $1,200, with a right to purchase for $30,000, and preparations are being made for an active output. And to all such enterprises every friend of the colony will bid God-speed.

A SUBSTANTIAL TYPE OF MARINE GENERATING SET.

In the design of the generating set illustrated herewith, the features of compactness, accessibility, economy and stability, with consequent lightness of parts, and ability to maintain an excessively high rate of speed during a long period, have, it is claimed, been most carefully developed.



The engine is two cylindered, the cylinders having their axes parallel, and being contained within the same casting. The diameter is very large relatively to the stroke, the size represented here being 9 inch cylinders with 5½-inch stroke. The valves, which are of the piston type, are two in number, placed in spandrels between the cylinders, and actuated from a yoke below, which in turn receives its motion through a rocker arm from the eccentric. The valves, which operate in unison, are so designed that steam is coincidently admitted to the top of one cylinder and the bottom of the other. The motion of the pistons is transmitted through large piston rods to slipper cross heads, and thence through marine type connecting rods to the double crank below. The crank pins are set at an angle of 180 deg., so that the vertical motion is balanced, one crank moving upward as the other moves downward. This feature is instrumental in the securing of a high rotative speed.

The cylinders are supported upon four heavy columns as shown, the rear columns supporting the guides for the cross-heads, and all being securely bolted at the bottom to the very substantial bed casting. This bed carries three main journal bearings, brass bushed in their lower halves, and provided with continuous oiling devices in connection with oil receivers beneath. The interior of the bed forms a basin, which collects all drip from water or oil.

The regulator is of special construction, and arranged to operate the valve in such a manner as to regulate the point of cut-off for all loads. It is exceedingly powerful, although sensitive to very slight changes in speed. The connecting rod and cross-heads are of forged steel, the cylinders are thoroughly lagged, and an oil tank is mounted upon each end of the cylinder casting, and provided with individual sight feed oilers, and connections to the various bearings.

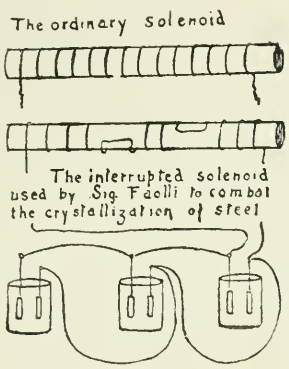
The generator, the armature of which is coupled to the engine shaft, is carried upon a continuation of the engine base, and is of the six pole type with outboard ring boiler bearing. Its capacity is 425 revolutions per minute (the speed of the engine is 40 k.w.). The field ring is of cast-steel. The cores are of wrought iron with cast iron shoes. The armature is built upon a spider, and is arranged for thorough ventilation through internal ducts, extending out through the armature windings. The armature in operation acts as a blower, and causes the passage of air through these ducts. The series winding of the field coils is of flat copper ribbon, and the shunt winding is of wire. Both windings are placed on the pole entirely independent of each other, and either may readily be removed. Their design is such as to permit of free circulation of air upon all sides. The generator is designed for sparkless operation under all changes of load from no load to 25 per cent. overload, with a limit of temperature rise to 90 deg. F., after a full load run of 10 hours. This set was designed by the B. F. Sturtevant Co., Boston, Mass.

Wilson & Smith, Worcester, Mass., are now occupying their new factory recently built for them, and though much more than the usual number of orders are in hand, they are filling them promptly. The firm is now carrying a larger stock of nuts and washers of all sizes than ever before. The chief output of this firm takes the form of specialties punched from cold iron, steel and brass and the making of dies for this class of work

OVERSTRAIN IN STEEL.

Owing to the large use of structural steel at the present time a great deal of interest is being taken in the question of the probable life of structures, such as high buildings, bridges, etc., which depend wholly for their strength upon this material. An Italian electrical engineer, Emilio Fealli, has just made a discovery, which he claims is a means of effectively preventing crystallization. A bridge at Setro Ponente, about ten miles to the north of Genoa, Italy, collapsed on three different occasions within a dozen years. Another bridge near Pavia had only just been constructed and was being tested when it snapped in the middle. Making a study of these accidents lead Signor Faelli to experiment with overstrained steel, and finally, when experimenting with what is known as a "tired" razor and an electric cement, he discovered that the application of electricity would restore strained steel. He tried an electrical current traversing a solenoid placed around the razor, the current being controlled by the intercalation of a tuning fork. On trying the razor he found it in a relatively good condition for its ordinary work. This was a proof that the crystallization had been partially nullified. His solenoid was one of perfect tubal curve, and he got better results with an interrupted spiral curve.

A solenoid, the coil of which is in one direction, carries current running in an unchanging course, and symmetrically magnetizing any soft iron that may be placed in its centre. A



solenoid, on the contrary, whose curve is interrupted, carries a current which changes with the frequency of the interruptions, and has peculiar effects on metal placed within it. It induces in the metal, independently of the extreme poles, as many interior poles as there are alterations in the coil.

The following is an abstract of a paper on the Recovery of Iron from overstrain, by Jas. Muir, B.Sc., Trinity College, Cambridge, which was communicated to the Royal Society by Prof. Ewing, F.R.S.:

It has long been known that iron which has been overstrained in tension—that is to say, strained beyond the yielding point, so that it suffers a permanent stretch—possesses very different elastic properties from the same iron in its primitive condition. The material is said to be "hardened" by stretching,[1] since the ultimate effect of such treatment is to raise the elastic limit, and reduce the ductility of the material.

More recently attention has been called to the fact that, primarily, the result of tensile overstrain is to make iron assume a semi-plastic state; so that the elastic limit instead of being raised by stretching is first of all lowered, it may be, to zero.[2] This plasticity may be shown by applying a comparatively small load to a bar of iron or steel which has just been overstrained by the application and removal of a large stretching load. When the small load is put on, the bar will be found to elongate further than it would had the material been in its primitive state; and a slight continued elongation—a "creeping" may occur after the small load has been applied. If this load be withdrawn a quite appreciable permanent, or semi-permanent, set will be found to have been produced; a set which diminishes slightly, and, in all, may vanish provided time be allowed for backward creeping to take effect. It may also be shown that if the reapplied load be increased the elongation produced will increase in a greater proportion. Thus if a stress-strain curve be obtained from a recently overstrained bar of iron or steel, it will show even for small loads a marked falling away from the straight line which would indicate obedience to Hooke's law.

It is recovery from this semi-plastic state induced by overstrain to a condition of perfect or nearly perfect elasticity, with raised elastic limit, that is referred to in the title of the paper of which this is an abstract. Such recovery is known to be effected by mere lapse of time,[3] and the object of the experiments described in the paper and summarized here, is to show the effect of moderate temperature, of mechanical vibration, and of magnetic agitation on this slow return to the elastic state; and, further to illustrate this recovery by means of compression tests. One section of the paper deals with the phenomenon of hysteresis in the relation of extension to stress which is exhibited in a marked degree by iron in the overstrained state. Incidentally attention is called to subsidiary points of interest.

The experiments were carried out in the engineering laboratory of Cambridge University, and were the outcome of suggestions by Professor Ewing. It was on his suggestion that the effect of moderate temperature on recovery from overstrain was tried, and the result of that trial led to much of the work incorporated in the paper. The straining and testing were done by means of the laboratory 50-ton testing machine, the specimens employed for the most part being taken from steel rods one inch in diameter, of a quality which may be described as semi-mild. The small strains of extension were measured by Professor Ewing's extensometer.[4]

After referring to the apparatus and the material employed, and describing the method of experimenting, there are first given in the paper examples of the slow recovery of elasticity with lapse of time. These examples are illustrated by stress-strain curves obtained, at succeeding intervals of time, from extensometer readings similar to those tabulated by Professor Ewing in his paper, referred to above, "On Measurements of Small Strains in the Testing of Materials and Structures." Recovery is shown to be at first comparatively rapid; but latterly very slow progress is made, and weeks or months may be required before an approximately perfect restoration of elasticity is effected. When this is brought about, the specimen may be subjected to a stress a few tons per square inch higher than that at which the virgin material yielded, before a yield-point is passed and the material once more brought into a semi-plastic state. If sufficient time be allowed to elapse after passing this second yield-point, an elastic state will again be assumed, and a third yield-point may be obtained about as far above the second yield-point as the second was above the first. In this manner four or five yield-points may be obtained with the same specimen before fracture occurs. A specimen broken in this manner shows greater ultimate strength, but less ultimate elongation than would have been obtained had fracture been brought about in the usual fashion, that is, without allowing intermediate recoveries of elasticity to take place.

The question of recovery of elasticity under stress is next considered in the paper, and it is shown that the process of recovery proceeds at practically the same rate whether the material is kept stressed or is allowed to rest free from load. A slight difference, however, is shown in the two cases, as restoration of elasticity takes place about the position of continued stress. After this, the phenomenon of hysteresis in the relation of extension to stress is considered, and a closed cycle is shown, having features analogous to those exhibited by a magnetic hysteresis cycle.[5]

The effect of moderate temperature on recovery from overstrain is next treated of, and it is shown that a slight increase in temperature hastens the restoration of elasticity to a remarkable extent. Three or four minutes at 100 C. proved to be more

efficient than a fortnight's rest at the normal atmospheric temperature. The effect of various temperatures below 100° C. is then investigated, and so moderate a temperature as 50° C. is shown to have a large influence in hastening recovery from overstrain. The manner in which recovery proceeds with time when the specimen is kept at a constant temperature is shown in the paper by means of curves. These curves show that at first—that is, before elasticity is fairly well restored—the amount of recovery, measured by the diminution in the elongation produced by a maximum load, is proportional to the square root of the time. For example, the effect produced by, say, four minutes at 80° C. was approximately double of that produced by one minute at the same temperature. By subjecting an overstrained specimen to temperatures above 100° C., no effect (other than the recovery from the temporary effect of overstrain) was found to be produced until a red heat was almost attained. When the specimen had been subjected to an annealing temperature, of course the whole effect of overstrain was removed, and the material assumed its virgin state.*

After the effect of temperature is discussed, that of mechanical vibration is next recorded in the paper; and it is shown that by striking a recently overstrained specimen with a hammer, so as to make it ring, the material of the specimen is made less elastic. That is, the effect of mechanical vibration is opposite to that of increase of temperature; recovery of elasticity is not hastened, but the material becomes more semi-plastic after mechanical vibration than it was before.

The influence of magnetic agitation is next described. A recently overstrained specimen was subjected to magnetic reversals by means of a coil giving a field strength of 1.40 C.G.S. units at its centre, but no change whatever was detected in the elastic condition of the material; the process of recovery seemed to be neither accelerated nor retarded.

For the compression experiments described in the paper, an instrument, specially designed by Professor Ewing, was employed to measure the small compressioned strains. By the aid of this instrument, the semi-plasticity of recently overstrained iron was readily observed, and the effect of moderate temperature in restoring elasticity was demonstrated by means of compression tests. The lowering of the compression yield-point which accompanies the raising of the tension one (due to tensile overstrain) was also clearly shown. This lowering, however, was not found to be such as to keep the total range of elasticity for the material constant; that is, the lowering of the compression yield-point was not found to be equal to the raising of the tension one. In conclusion, the characteristics of overstrained iron are considered as illustrating Maxwell's views on the "Constitution of Bodies," as set forth by him in the "Encyclopaedia Britannica."

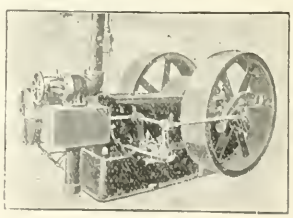
Hoping we may soon have things adjusted to your satisfaction I reman as ever

Fort Worth, Texas, July 3rd, 1899. J. M. Robbins.

THE PEERLESS SELF-OILING AUTOMATIC ENGINE.

We here illustrate this new modern self-oiling engine now placed on the market by E. Leonard & Sons, London, Ont. The makers claim every possible improvement in connection with it that is now in existence on the best class of engines offered for sale in the United States or Canada. The points of great advantage claimed are as follows: The engine bed is of a new type, most rigidly designed to withstand high pressure steam; the governor is Ball's latest patent, Class E., much simplified, only having one spring and weight, and made now without the dash pot; it is so perfect in regulation that it will not vary 1 per cent. from no load to full load; the engine valve is perfectly balanced, has a double face and cannot leak. This firm have engines that have been in constant use for fifteen years, and never yet a case of leakage, and have no record of having any of these repaired. The self-oiling system supplies oil at a proper height in the body of the frame, so as to lubricate the crank, cross-head and the engine bearings, without the least appearance of oil shown outside of the engine, doing away with all oil cups in this location. The engine shaft is made of forged steel. The cross-head is of steel, of the new slipper type, and is adjustable. The cross-head has very large wearing surface. A space is left between the cylinder and gland, which prevents the water following



the rod into the frame of the engine. The main bearings can be adjusted when the engine is in operation. All of the parts are made of the best material and workmanship, and the fixtures, as shown, are first-class in every way.

The recent sales made by this firm include: W. H. Fowler (tandem compound), St. John, N.B.; Acadia Electric Co. (tandem compound), Wolfville, N.S.; London Electric Co. (simple direct connected), London, Ont.; United Electric Co., of Toronto, Ont., for Henry Morgan, Sons & Co. (simple direct connected), Montreal, Que.; Electrical Construction Co., of London, Ont., for Victoria Hospital (simple direct connected), London, Ont.; Anderson Furniture Co., Woodstock, Ont.; Bennett Furnishing Co., London, Ont.; Messrs. D. W. Karn & Co., Woodstock, Ont.; Anderson Furniture Co., Woodstock, Ont.;

W. & W. A. Hutchinson, Berwick, N.S.; H. Webster, Norwich, Ont. This firm have the following agencies: H. E. Plant, 109 Common street, Montreal, Que.; Geo. H. Evans, 62 Water street, St. John, N.B.; Thomas Nopper, traveling agent for Western Ontario, London, Ont.; Stuart & Harper, Winnipeg, Man.

THE MANUFACTURE OF STEEL FOR BUILDING CONSTRUCTION.*

BY F. H. KINDL.†

The first portion of the paper described in a popular way the processes which are gone through in the reduction of the iron ore, the conversion of the molten metal to steel, and its rolling into structural shapes. The paper then continues as below:

It is evident that for every different size beam, channel, or other shape, the entire set of rolls, from the cogging mill to the finishing rolls, must be changed; that is, the rolls and couplings must be removed and others put in their places. They must be reset and lined up true, so as to produce the proper design and weight of shape in the finishing pass. The weight of material moved—that is, rolls, couplings, etc., to be reset and relined—amounts to very nearly 175 tons in the large beam mill; and right here, gentlemen, it will become apparent to you that owing to the time required in roll changes we have a heavy factor in the time of delivery or, better, non-delivery in fixed time of your client's material. The cost of changing rolls, you can also see, must be considerable, and if we take but $1 per ton for labor of moving and resetting we have at once $175, and a proportional amount for the smaller mills, noting that no account is made therein for the cost of skilled labor required to reset and line up the rolls, taking from three to ten hours, depending upon the mill required to be changed.

A great deal of time is also required to change from one weight to the same shape and depth of another weight, so you can readily appreciate how it can occur that one building is erected so much quicker than another, and, I dare say, cheaper to your client, due simply to the use of standard sizes and shapes throughout in the construction of the steel skeleton, noting that the fewer the sizes used the quicker can the work be delivered. While this tendency toward the use of standard shapes has been very marked in the past few years, it could still be extended further, and it will no doubt interest you to know that in countries using the metric system architects and engineers long since adopted a standard of shapes, in conjunction with the mills, which are strictly adhered to, and none but the minimum weights in a fixed size are ever used. I am sure the sooner we adopt such a system the better it will be for all concerned.

But we must not forget our beam, which, no doubt, by this time, has left the last pass, or finishing pass of the rolls, and is now lying on the long roll table, ready to have a test piece cut from it and stamped with its blow number, representing the constituents of the steel, and to be cut into ordered lengths. The test piece is carefully prepared and sent to the testing laboratory, where its elastic limit, ultimate strength, and elongation and fracture are carefully measured and recorded, with the chemical constituents. The finished beam, cut to length, which has, until now, been lying flat on its side, is automatically turned up so as to rest on its flanges, as in its normal position in a building, and is quickly pulled across a series of rail skids, called cooling beds. Here it is allowed to rest until its turn comes to be straightened. The straightening machine is in direct line with the end of the cooling bed, and the beam is automatically guided through the machine, coming out of same true and ready to be shipped direct to destination, if plain, or transferred to the fitting shop, if work is to be performed thereon. Practically the same manner of manipulation as for beams applies to channels, rails, and other shapes.

For plates, the ingot is first reduced to a slab in the preparatory mill—called slabbing mill—which slab, as a rule, is reheated and then rolled flat to the required width and thickness in a plate mill. Plates having a width of over 48 inches or less than ¼-inch thick are rolled in an ordinary plate mill—that is, one having only horizontal rolls—and plates rolled in such a mill must have their edges sheared in the direction of the length of the plate, subsequent to rolling and straightening. For plates under 48 inches in width and over ¼-inch thick, this shearing is not necessary, as true edges can be obtained in a plate mill having, besides the same horizontal rolls as the ordinary plate mill, a set of vertical rolls. Such a plate mill is called a universal plate mill.

Plates 6 inches and less in width are worked in grooves cut into rolls similar to those for shapes, and can be rolled in the same way as shapes. It being a less expensive process than that used for plates, most bars are rolled in this manner.

All plates, after being rolled to the required width and thickness, are apt to be buckled, owing to internal stresses or unequal heating at different points of the plate, and must be straightened by means of subsequent rolling. A set of these straightening rolls is placed in line with the feed table in the plate mill, and the plates are automatically conveyed through them, being still quite hot. They are then carried on a long roll table to the template department, and there laid off to template, all this being performed while the plate is on the roll table. They are then carried along to the shears, placed at the extreme end of the plate mill department, and cut to the template marked thereon. From here they are directly shipped to their destination.

Having now completed the rolling of our plain material, we will visit the fitting shop for beams, where all our beams and channels are sent to be fitted, i.e., either to be—1st. Punched in web only, one or more size holes. 2nd. Punched in flanges only, one or more size holes. 3rd. Coped on one or both ends, after being punched. 4th. Riveted with connecting angles on one or both ends. 5th. Riveted into beam girders, with one or more cover plates. 6th. Bent or forged in blacksmith department.

As soon as the operation of the beams through one or more of the above processes is complete, i.e., when fitted as required by shop details, they are slid into the shipping yard on skids, ample room being left for this purpose between the different machines. Naturally, the less work to be performed, the sooner can the beam or other material be shipped, and in this respect the architect can materially assist in his plans and specifications. We will draw attention to some of the worthy points to be considered; noting, however, that they are not necessarily applicable in all cases, and good judgment must govern their use.

First. Specification, if possible, should call for only one size of hole to be used, namely, ¾-inch diameter, thus avoiding two operations and handling of material from one punch to another. Second. Avoid coping by setting the floor beams sufficiently below the top flange of the main beam or girder, providing this latter is of sufficient depth. Third. Avoid beam box girders, by the substitution of beams of greater depth. Fourth. Avoid blacksmith work—that is, bending, welding, etc., by proper design of riveted members.

We now take a hurried look at the column shop, and here are found machines to perform the workmanship on the various classes of material, which, after first being laid off and punched, are assembled and subsequently riveted together to the finished column, which is then faced to the exact length; noting that all parts inaccessible after riveting are painted.

The total cost of the structural steel erected in a building, of course, depends upon the weight required and the current quotations for the plain material, as well as upon the workmanship thereon, its hauling to and erection at the building site. The weight of structural steel in a building is very difficult to estimate, unless plans and specifications are first drawn up, as this will depend upon the design, the number of stories, the dead and live load to be carried per square foot of floor, the weight of brick or stone work resting on the outside girders, and the allowable unit stresses on the steel. While the allowable stresses per square inch are pretty well determined by our building laws, which are almost identical with each other, yet the former factors are of so wide range as to make each individual case different. However, for the weight of the steel skeleton of the average office building, whose walls are car-

*Extract from a paper read at the 33rd annual convention of the American Institute of Architects, at Pittsburg, Pa.

†Structural Engineer Carnegie Steel Company, Limited.

ried by the steel work, we have found by careful records of the weight of steel required that the following formula can be used with sufficient accuracy for preliminary estimates:

$W = N \times F\ (15 + 7/10\ N)$, in which "W" is the total weight in pounds of the structural material required: "N" is the number of floors, including the roof as a floor, and "F" is the number of square feet in each floor. The first number inside of the parenthesis when multiplied by the quantity N F, will give the weight of the beams and fittings required in the floors, while the second number multiplied by the same factor represents the weight of the columns. Thus we have for the weight of the skeleton steel for such a building, having a floor area of 10,000 square feet and 15 stories high, 2,400,000 lbs. of beam work and 1,792,000 lbs. of column work, or a total of 4,192,000 lbs. of steel work.

As regards the cost, while this will vary somewhat, due to design, we might safely assume that unless the construction is complicated, owing to an irregular lot line or unusual construction such as is found in theaters, music halls, etc., the average cost for fitting beams will seldom exceed ½ cent per lb. above the price of plain material, including the painting, and for column work, 1¼ cents per lb. above the price of plain material. We have, therefore, for our building noted above, assuming that the price of plain material will average 2 cents per lb., the cost of the beams would be 2½ cents per lb., and that of the columns 3¼ cents per lb., or a total cost of, beams, $60,000, columns, $58,240, and a total amount of $118,240 for the steel work f.o.b. cars Pittsburg, painted. To this must be added the cost of freight, hauling and erection. The hauling can generally be done for 50 cents per ton, while the erection will seldom exceed $6.50 per ton, thus making the hauling and erection $7 per ton. The hauling and erection of the steel for our building would therefore be $14,672, making a total cost of $132,912 for the steel work, erected in Pittsburg, as per your plans and specifications. These figures are kept somewhat on the safe side, and appear high to-day, owing to the use of a base price of 2 cents per lb. for the plain steel, which, as you know, is almost double the market price of one year ago. Since writing this paper the price of steel has again advanced and the cost of our building would now be very nearly $15,000 more.

HEATING.

In the progress of civilization more efficient arrangements for heating have gradually been adopted. Fire-places, stoves and furnaces have, in the order named, been introduced as means of warming. For small rooms, as in dwellings, they answer very well; but the effect of opening or closing windows and doors, and of changes in the atmospheric conditions, is too well appreciated to need recital here. It will certainly be admitted that a building can seldom be found where the heated air is properly and satisfactorily furnished and distributed by a furnace; some of these influences are sure to act, and at times it will be impossible to heat certain rooms without the closing of doors or shutting of registers in other rooms.

More exact are the methods of heating which are dependent upon the use of steam or hot water, confined in radiators or coils. Under systems of direct radiation, these are placed in the rooms to be heated, but seldom with any provision for the introduction of fresh air. By the indirect method of placing the heating surface in ducts connecting with the rooms and permitting outdoor air to pass across such surfaces, a much nearer approach is made to good ventilation. But still it is practically impossible by such mean alone to produce the air-flow, and maintain the temperature necessary for a large and crowded apartment. It is evident that some positive means, like the fan, must be applied to render such systems reliable at all times. Experience has demonstrated that in this climate no system of ventilation can be successfully operated by itself and independently of the method of heating that may be adopted. It is, in fact, a vital element of success that the two systems must be most intimately combined, for they are clearly interdependent, and when properly applied are so interwoven in their operation and results that disunion is certain to bring about failure. For the purpose of ventilation, the fan was first applied upon a practical scale about the middle of this century, but only to a limited extent, and it was not until the fan and steam heater in marketable form were introduced by B. E. Sturtevant, that the so-called "Blower System" became a reality. This system is at once practical, successful and economical; for air being the natural conveyor of heat, it may, when properly warmed and supplied, perform the double office of heating and ventilating. As applied, the Sturtevant system forces the air into the apartment by the pressure or plenum method. When a fan is arranged to exhaust or withdraw the air from an enclosed space, the term vacuum, or exhaust method, is almost universally applied.

There are many objections to the adoption of the exhaust method in this country, and, as a rule, it should be avoided. When exhausting, a partial vacuum is created within the apartment, and all currents and leaks are inward; there is nothing to govern definitely the quality and place of introduction of the air, and it is difficult to provide proper means for warming it. Under this system provision is often made for drawing the air across steam pipes placed opposite windows, with the expectation that the air will become thoroughly heated in passing across them. Such often fails to be the case, for the most direct course is taken by the air toward the existing vacuum, and only a portion of the heating surface is utilized. On the other hand, when air is forced in, its quality, temperature and point of admission are completely under control; in a word, the method is positive; all spaces are filled with air under a slight pressure, and the leakage is outward, preventing the drawing of polluted air into the room from any source. But, above all, ample opportunity is given for properly tempering the air by means of heaters, either in direct communication with the fan itself or in separate passages leading to the various rooms. —From B. F. Sturtevant Co.'s Treatise on Ventilation and Heating.

GENERAL PRINCIPLES OF THE GAS ENGINE.

The general principles of the gas engine are explained in an article by E. W. Roberts in a recent number of Machinery, from which the accompanying illustrations are reproduced.

It will be necessary to briefly consider the series of operations which take place in the cylinder of a gas engine. With the exception of the Diesel motor, described in the last issue of The Canadian Engineer, all gas engines now being manufactured employ the Beau de Rochas cycle. The series of operations which comprise this cycle was first proposed by M. Beau de Rochas in 1870. It was not, however, put into practical form until it appeared in the first Otto engine in 1876. For this reason it is quite frequently called the Otto cycle, although the honor of its conception belongs unquestionably to Beau de Rochas. There is also in use a modification of this cycle in which a portion of the necessary operations are carried on in a separate device or its equivalent in order to permit the entire cycle to be completed during one revolution of the crank-shaft instead of two revolutions as required in the Beau de Rochas cycle.

The series of operations which take place during the four piston strokes necessary for the completion of the entire Beau de Rochas cycle is as follows: During the first forward stroke, gas and air are drawn into the cylinder and this mixture—called the charge—is compressed into a space at the end of the cylinder into which the piston does not enter. Just before the piston reaches the end of the compression stroke, or in some engines just as it reaches the end of the stroke, the charge is ignited. The ensuing explosion gives rise to a sudden elevation of pressure and temperature and during the next forward stroke the products of combustion expand. Just before the end of the expansion stroke, the exhaust valve is opened, permitting the contents of the cylinder to escape to the atmosphere. The following return stroke clears the cylinder of burnt gases, more or less thoroughly, according to the design of the engine.

The foregoing series of operations will be better understood by reference to Fig. 1, in which the indicator diagram given by the engine is placed immediately over the cylinder. For convenience of reference, the stroke of the engine is divided into ten equal parts, and lines are drawn from the cylinder to the diagram. Similar letters refer to the same point of the cycle and the letters are primed upon the diagram and capitalized upon the crank circle. The suction stroke starts at (c), the charge being drawn through the valve (v). Upon the return stroke, the admission valve (v) is closed and the charge is compressed into

the space between the piston (P), when at the end of the return stroke and at the end of the cylinder; that is, into the compression space. The point of ignition is indicated upon the diagram at (d). As shown by the diagram, the pressure rises more rapidly at this point than during the early part of the compression stroke and at the end of the stroke the charge becomes

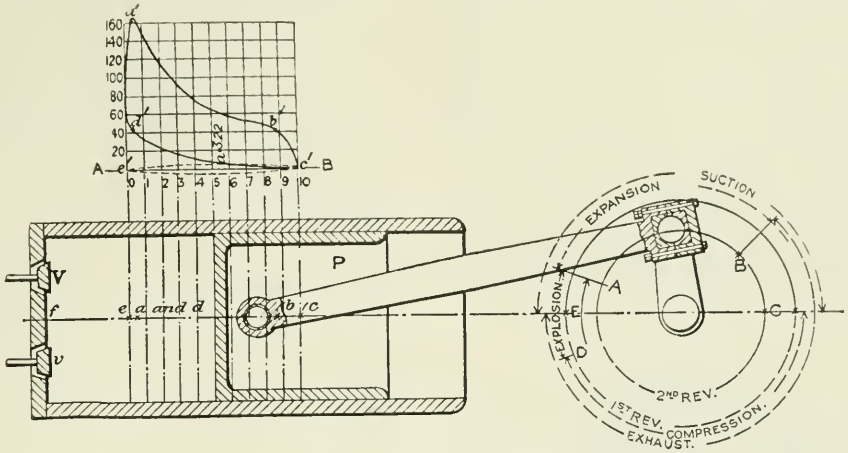


FIG. 1—SHOWING THE ACTION OF THE ENGINE.

fully inflamed, the pressure rising with great rapidity until the point of maximum pressure is reached, just before the piston starts on the expansion stroke (a), (b). The exhaust valve (V) opens just as the piston reaches (b), and from this point to the end of the stroke the pressure falls much faster than during true expansion. Upon the second return stroke, or while the piston is passing from (c) to (e), the products of combustion are driven from the cylinder.

The cycle is given in tabular form for easy reference:

1st Revolution—Forward stroke; suction. Return stroke; compression, ignition, explosion.

2nd Revolution—Forward stroke; expansion or power stroke. (Release).

The indicator diagram which is given in Fig. 1 is shown on a larger scale in Fig. 2. To have his engine produce such a diagram should be the goal of every gas engine designer. There appears to be no reason why such a goal may not be reached by everyone, since the diagram is an enlargement of one actually taken from an engine operating on the Beau de Rochas cycle. In the writer's experience the most successful engines operating on the market to-day are giving just such diagrams.

The notable points about the diagram shown in Fig. 2 are as follows: The compression curve is smooth and is a regular curve from the beginning of the compression stroke to the point of ignition. The gas ignited at (i), is fired just early enough to bring the point of maximum pressure at the beginning of the forward stroke, and the line (ab) indicating the rise of pressure lies at right angles to the atmospheric line (x), (y). The expansion line is smooth and does not show a series of steps as the pressure decreases. The release or point at which the exhaust valve opens is at (c), and it occurs at the proper moment to bring the point (d), where the expansion line meets the atmospheric line, directly at the end of the stroke. Wire-drawing on the suction and on the exhaust strokes would be indicated by a line similar to (xsy). The writer is aware that there is some difference of opinion regarding what constitutes an ideal gas engine diagram. This is especially true with reference to the point of stroke where ignition should take place. The majority are in favor of such a diagram as is recommended.

The diagram shown in Fig. 3 is a puzzling one. The wavy appearance of the expansion line is produced, not by conditions within the engine itself, but by the vibration of the indicator spring. A somewhat similar diagram might be expected from a badly mixed charge, in which case the rising side of the wave would be much steeper than the falling side.

Fig. 4 is reproduced from an actual diagram, and shows the effect of late ignition, which takes place at (i) after the piston has started on the power stroke. The amount of work which is lost because of the delayed firing is indicated by the area enclosed within the dotted line at the left of the diagram proper. No better argument for early ignition could be given.

When the mixture of gas and air is exploded at atmospheric pressure the resultant action of the gases depends upon two conditions, one of which is the quality of the combustible gas, and the other the proportionate amount of this gas to the air contained in the charge. A series of experiments made by Dugald Clerk, the well-known English gas engine expert, gave results which show the action of these mixtures. Mr. Clerk employed for his experiments the apparatus illustrated in Fig. (1). A chamber E, 7 inches in diameter by 8½ inches high, contains the mixture to be tested. A steam-engine indicator I, was attached to the explosion chamber E and the drum of the in-

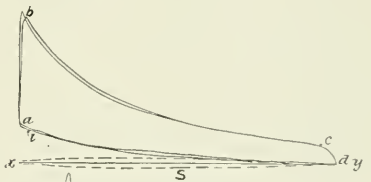

FIG. 2

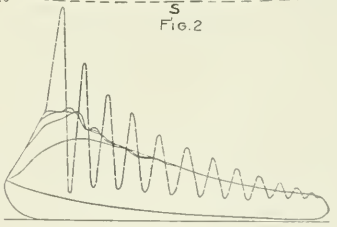

FIG. 3

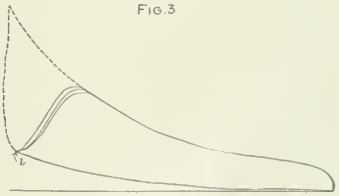

FIG. 4

dicator was operated by clock work as shown. The power to run the clock train was supplied by the weight W, and the speed regulated by the fan (F). By means of this arrangement, the pressure exerted in the chamber (E) was transmitted to the piston of the indicator, which in its turn raised the pencil (q). In the conduct of the experiments a carefully measured and proportioned mixture of gas and air was drawn into the chamber

(E), and the gases fired by means of an electric spark. The drum having already been set in motion, the pressure of the gas exerted on the indicator piston, compressed the springs raising the pencil (q). The pencil left a record upon the drum in the form of a curve somewhat similar to the upper portion of the ordinary gas engine diagram; vertical distances, measured on the line (xy) representing pressures and horizontal distances measured on the circumference of the drum representing intervals of time. With this piece of apparatus the successive alterations of pressure, from the time the gas was ignited until it had reached a pressure closely approaching that of the atmosphere, were determined. Nine of the curves thus obtained are shown in Fig. 10, and they illustrate the action of one variety of gas when mixed with air in various proportions. The different curves may easily be distinguished by the aid of the letters a, b, c, etc., which are placed at each end of the diagram.

Curve	a	b	c	d	e	f	g	h	i
Volumes of air to one of gas....	14	13	12	11	9	7	6	5	4

In this figure, only that variation of pressure which takes place during the first second is shown. The line (x y) is divided into twenty equal parts, each one of which represents a lapse of

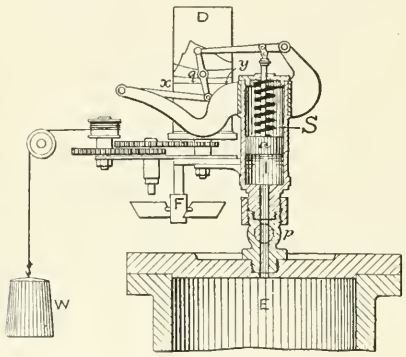

Fig. 5.

.05 second. The distance between each horizontal line represents a difference of pressure of five pounds. The time is measured from the moment when ignition takes place as indicated by the rise of pressure.

A careful study of the curves will show that when the mixture is weak in gas, the rise of pressure is very low, the time between ignition and the moment when the gases reach their maximum pressure being nearly .45 seconds for curve (a) and but .04 seconds for curve (g). This lapse of time indicates very closely the fraction of a second it takes for the gas to become one entire mass of flame, or to express it differently, the time required for full inflammation. The rate at which the pressure rises after ignition is indicated by the inclination of the curve. This inclination is of course very steep when inflammation is most rapid, and the inclination decreases as the rate of inflammation is lowered, the curve becoming more nearly parallel to the lines (xy). The rate of fall of pressure is indicated by the inclination of the line beginning at the point of maximum pressure and continuing to the right of the figure. This rate of fall is not shown as far as the point where the pressure of the mixture reaches that of the atmosphere. It may be stated that this point was reached approximately 1.88 seconds after the time when the ignition took place

It must not be thought that when the mixture is totally inflamed the gas has been entirely consumed. A peculiarity of such mixtures as this is that at the high temperatures produced in the gas engine a certain proportion of the gas remains uncombined with air and is not burned until a lower temperature has been reached. The effect of this phenomenon, called dissociation, is that heat is constantly being added to the mixture by this late combustion, keeping the pressures upon the expansion line much higher than could be obtained without it, under the conditions which are present in the cylinder. This phenomena is no detriment to the operation of the engine, but is rather in the nature of an assistant. It must not be thought that the mixtures of gas and air which give the most violent explosions and consequently the highest initial pressures are the most economical to use. An illustration of this is given in the table shown below, the data being taken from the curves in Fig. 6:

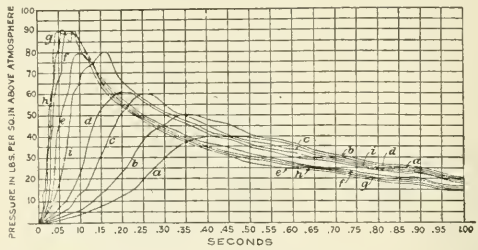

Fig. 6—Showing Effects of Explosions.

1	2	3	4	5	6	7	8
Volumes of air to 1 volume gas.	Proportion of gas in mixture.	Maximum pressure in lbs. per sq. in.	Area of piston to each cubic inch of gas.	Total maximum pressure per cubic inch of gas.	Pressure per sq. in. .2 seconds after maximum.	Total pressure to each cubic inch of gas .2 seconds after maximum.	Mean pressure on 1 sion for first .2 seconds after maximum.
14	1-15	40	15	600	31	465	532
13	1-14	51.5	14	721	40	560	640
12	1-13	60	13	780	42	546	663
11	1-12	61	12	732	44	528	630
9	1-10	78	10	780	44	440	610
7	1-8	87	8	696	47	376	536
6	1-7	90	7	630	52	364	497
5	1-6	91	6	546	50	300	423
4	1-5	80	5	400	46	230	315

Although the above table shows what would take place in an engine having no compression, and which draws the charge in for about half the stroke and then ignites it, it is of assistance to the designer in judging of the action of gases and in choosing the best mixture for a given engine. That proportion of gas to air which gives the highest pressures for the quantity of gas used, is undoubtedly the best. For instance, let the distance between the end of the cylinder and the piston be exactly one inch; then there will be one square inch on the surface of the piston for every cubic inch contained in the above space. In order to calculate the highest pressure which will be given with a certain quantity of gas proceed as follows: If the mixture contain one volume of gas to seven of air, there will be eight cubic inches of the mixture for each cubic inch of gas, and in a layer one inch deep the surface of the layer will be eight square inches. Since in the preceding table the maximum pressure for a mixture of the above proportion is 87 lbs. per sq. in., the total pressure exerted by each cubic inch of gas is $87 \times 8 = 696$ lbs.

That mixture which gives the best mean pressure for the first .2 sec. is that which gives 663 lbs. mean pressure to each cubic inch of gas. This mixture is that containing 1 volume of gas to 12 of air. Could the power stroke be considered as taking place without increase of volume, the pressure given in column 7 would be that remaining at the end of .2 sec. and that given in column 8 would be the mean pressure for the same length of time. Thus the figures in column 8 give a means of comparison of the powers to be obtained with the corresponding mixtures indicated in column 1. For instance, that mixture having one volume of gas to 13 volumes of air has more than double the power of the mixture containing one volume of gas to four volumes of air, the ratio being 640 to 315, the power considered being that available during the first .2 sec. after maximum pressure. Do not imagine that an engine could operate without increasing the volume of the cylinder; this assumption is taken as a convenient means of comparing the values of the various mixtures. It is important that in each of the above cases the gas be considered as if it gave its maximum pressure at the beginning of the stroke.

The Maritime Spice and Coffee Co., which has lately been organized at St. John, N.B., has ordered a 40 h.p. engine and boiler from the Robb Engineering Co.

THE INTERNATIONAL CORRESPONDENCE SCHOOLS IN TORONTO.

The International Correspondence Schools, of Scranton, Pa., have just opened an office in the Temple Building, Toronto, No. 413, where they will make their Canadian headquarters. At these offices they have every facility for explaining their new system of education, and E. A. Seitz, the superintendent of the schools for the Dominion of Canada, tells us that all interested in technical education will be heartily welcome to examine their work, and look over the instruction and question papers of the different courses of instruction. There are two features in connection with the establishment of these offices of the International Correspondence Schools in Toronto, which are claimed to prove of great benefit to seekers after technical information along trades or profession lines. First, the schools propose giving a course of lectures for the benefit of students and friends, on the subjects of Electricity and Steam Engineering. F. Philip, the well-known superintendent of the mechanical department of the T. Eaton Co., will give a number of practical talks in connection with this series of lectures. Similar discourses, from a practical standpoint, will be given by others prominent in the various branches of engineering in Toronto. These lectures have no connection with the regular correspondence course of instruction carried on by the schools. The schools will also have at their Toronto offices complete sets of the instruction and question papers of all of their courses of instruction, handsomely bound. The range of subjects covered by these volumes will, the schools claim, make this the best technical reference library in the city. The students of the schools in Toronto will have the privilege of using this reference library at any time, the offices being open during the day and until 10 o'clock in the evening. The International Correspondence Schools have met with great success in their field of work. They state that they now have $1,500,000 invested in carrying on this system of education. They have over one thousand employees, and the buildings of the schools at Scranton, Pa., were erected at a cost of $250,000. In Canada alone the schools at present have over three thousand students and graduates. The remarkable success of the International Correspondence Schools is due to the fact that they give the kind of education needed. They enable men to pass the dead line of mediocrity, and make their way to the best positions in the engineering trades and professions. The schools point with pride to the army of students whom their instruction has placed in independent positions. The International Correspondence Schools claim to have solved the problem of how to educate the people. That problem, briefly, is how to put within the reach of the wage-earner the kind of education that will qualify him to climb the ladder of success. They believe that they have a perfect system, and it will well repay any wishing to better inform themselves along the lines of their work to examine into the practical results that have been accomplished by this system of study.

A TEST OF MECHANICAL DRAUGHT.

The possibilities in the way of reduction of fuel cost in modern boiler practice by the introduction of mechanical draught, are well exemplified by the accompanying results obtained at the United States Cotton Co., Central Falls, R.I. This record covers a period of 52 weeks, during which the number of hours run was 2,998, and the average indicated horse-power was 1,543.84:

Kinds of Coal.	Pounds burned.	Cost.
Buckwheat	6,074,400	$7,316 89
Anthracite	1,173,826	800 34
Cumberland	565,906	836 00
Total	7,814,132	$8,953 23

Cost per ton, $2.29. Cost per I. H. P. per year, $5.80.

Composition of Mixture:

Buckwheat	78 per cent.
Anthracite dust	15 per cent.
Cumberland	7 per cent.
	100 per cent.

The plant consists of three Babcock & Wilcox boilers of 325 rated h.p. each, a total of 1,005 rated h.p. The engine is a cross-compound Harris-Corliss, developing as will be noted, an average of 1,543.84 indicated h.p. The remarkably low fuel cost of $5.80 per I. H. P. per year in a plant without economizers, is primarily due to the employment of a low grade mixture costing only $2.29 per ton, the burning of which has been rendered possible by the introduction of mechanical draught. The draught of the chimney, which was previously employed, lacked the intensity necessary to the free combustion of this fuel, and as a consequence it had been necessary to use Cumberland semi-bituminous coal. The installation of the fan, costing less than $600, brought about an annual saving of no less than $6,500 in the fuel bill. The fan, which was built by the B. F. Sturtevant Co., of Boston, is provided with a direct attached engine, the speed of which is regulated by a device of the Sturtevant Co.'s chief engineer, Thos. P. Burke, whereby a slight change in the steam pressure alters the speed of the fan, and consequently the intensity of the draught, and brings the pressure back to normal. As a result, it is claimed that the steam pressure remains almost constant.

THE TURBINE STEAMER.

At the meeting of the British Association for the Advancement of Science, held at Dover, a paper was read by the Hon. Charles Parsons, the inventor of the Parsons' steam turbine, in which he said that the compound steam turbine engine had been so fully described in the proceedings of the Institution of Civil Engineers and the Institution of Mechanical Engineers and the Institution of Naval Architects that it was only necessary to refer to its leading features when designed for the propulsion of fast passenger vessels. Generally speaking, it might be said that the larger the size of the propelling machinery of the steam turbine class the more favorable are the conditions for securing the highest degree of economy in steam with a minimum of weight and the greater the simplicity of the machinery. For fast passenger vessels, and especially for cross-channel service, the turbine system of propulsion offers great and important advantages over the ordinary screw or paddle engines. In the first place, the steam consumption of the turbine engines is no more—perhaps somewhat less— than the best ordinary triple compound engines. The weight of engines, shafting and propellers is under one-half that of ordinary screw engines, shafting and propellers, and under one-third that of ordinary paddle engines of the same power, so that there is much less weight to be propelled; besides this, the hull itself may be of lighter structure than is admissible with ordinary engines owing to the absence of racking stresses from the machinery. With turbine engines no lubricant whatever enters the steam part, so that the boilers become much less charged with oil than is the case with ordinary engines, and express water-tube boilers of the smaller tube type may be maintained in satisfactory working conditions for long periods; and, further, it is understood that the Board of Trade will be prepared to so modify their system of periodic inspection as to permit of such boilers being used for regular cross-channel service. But perhaps the most important considerations are the increased comfort to passengers, owing to the absence of vibration and a remarkable smoothness of motion analogous to that of a sailing vessel, also the greater depth at which the propellers are placed below the surface of the water, reducing the liability to racing of the engines, which enables the speed of the ship to be maintained in heavy weather in a way that is totally impossible in the case of ordinary screw or paddle vessels. A model was exhibited in the hull of a proposed cross-channel boat of 30 knots sea speed in moderate weather. If a service of 30 knot vessels were placed on the Newhaven and Dieppe line, it would become the fastest route from London to Paris; also if the system were properly carried out as suggested, the time on the Dover and Calais route between London and Paris would be shortened by about half an hour, and the duration of the sea passage much reduced. The draught of water with turbine engines does not necessarily exceed that of paddle-wheel vessels, and, as turbine engines are more readily and quickly manipulated than ordinary engines, and each side of the propelling machinery can be put ahead or astern independently, the manoeuvring power is practically equal to that of paddle-wheel propelled

essels. The particulars of the proposed 30-knot turbine boats are as follows: Length, 275 feet; beam, 30 feet; depth (moulded) 13 feet 1 inch to main deck, 21 feet to awning deck; draught, 9 feet 3 inches (about): displacement, 1,000 tons (about); speed, 30 knots; i.h.p., 18,000. Professor Dunkerley, in the discussion on Mr. Parsons' paper, gave some details of the trials made, by Professor Ewing, of Cambridge, with the Turbinia, in which the speaker had also taken part. From the experience he had gained he then came to the conclusion that the steam turbine invented by Mr. Parsons would play a most important part as the motor of the future. Since that time further improvements have been made for marine propulsion, and he was now looking forward to the time when the crude instrument known as the reciprocating engine would be almost a thing of the past. The difficulty met with in going astern had been reduced. Mr. Barker, of Cambridge, the engineer to the Cambridge electric light station, bore testimony to the desirability of the steam turbine and the very small amount spent on repairs and renewals. This he gave as the result of a six years' experience. Captain Lloyd stated that in a preliminary trial of the day previously an Elswick destroyer with Parsons' turbine machinery had made 32 knots. He referred to the advantage given in a war vessel by the complete absence of vibration in regard to laying guns accurately.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

The regular meeting of this society was held on Thursday evening, November 23rd, in the rooms of the society, 112 Mansfield street, Mr. St. George, vice-president, in the chair. After the reading of the minutes by the secretary, Prof. C. H. McLeod, a brief discussion took place as to suitable places for holding the next annual meeting; a lecture was delivered by Professor R. B. Owens, of McGill University, on the "Electrical Transmission of Power," the first of a series of lectures on the same subject, to be given during the winter.

Professor Owens commenced by stating that a distinction should be drawn between the "transmission" and "distribution" of power, the former referring usually to the transfer of energy over distances of five miles and upwards, and the latter to the transfer of energy in and about buildings, for lighting, and tramway service in cities, etc. The present lectures will deal with the problems of power transmission rather than those of distribution. He stated that as the development of power is distinct from its transmission and distribution, and had often been treated in previous papers before the society, it would only be considered incidentally.

Perhaps the first long distance transmission of power by electrical means was effected by Marcel Deprez, who nearly twenty years ago transmitted some 3 h.p. a distance of 25 miles over ordinary telegraph wires at a pressure of 2,000 volts, and obtained at the motor about 30 per cent. of the energy expended, but it was not until 1890 that the full capabilities of electricity, as a means of transmitting power to great distances, was appreciated. That year, in connection with the Frankfort Exhibition, some 200 h.p. was transmitted by 3-phase alternating currents at a pressure of 8,500 volts from Leuffen to Frankfort, a distance of 110 miles, with total losses of only about 30 per cent. Reference was made to the greatly increased use of alternating currents for power transmission, and distribution in recent years, but attention was also called to the many sources of trouble which a manager of an alternating current plant has to contend with, such as diminution of machine capacity with power factor of load, etc., many of which, he said, would disappear were continuous currents used. Several continuous current transmission plants in Europe were referred to. The general characteristics possessed by standard direct and alternating current apparatus were then discussed, and the usual methods for obtaining efficiency regulation, temperature, etc., of the machines given. His remarks were illustrated by large wall diagrams, showing the analysis of losses in several machines, efficiency and regulation curves, etc., under different conditions. Generally speaking, a large amount of copper and a small amount of iron mean good efficiency at light loads, but poorer regulation. With the majority of Canadian waterpower plants only maximum efficiency need be considered, as there was generally a surplus of power. Attention was called to the fact that in direct current generators, the multi polar type had nearly if not quite displaced the older bi-polar form, the reason being better commutation and slower speeds. The Lamme form of cross-connected armature was described and its advantages pointed out. A number of lantern slides were here shown, illustrating the various standard types of electrical machinery now in use, among them being a 1,500 k.w., double current generator of the Chicago Edison Co., a 1,500 k.w. revolving armature 2-phase alternator, used in the Snoqualmie Falls transmission plant; a 750 k.w. 3-phase revolving field alternator, as used at Lachine; a 2,000 h.p. inductor type of generator as used at Chambly, and several typical water-power transmission plants, as the St. Anthony Falls plant, the Mechanicsvilles (N.Y.), and the Big Cotton Wood plant, near Salt Lake City. In discussing the arrangement of apparatus in the generating station, among other points, the lecturer advised that exciters be all independently driven. Diagrams, showing the arrangement of winding for single polyphase generators and motors, were then shown. Attention was called to the importance of E.M.F. wave form in the parallel operation of alternators and in the operation of synchronous and induction motors and a number of actual wave forms were shown as obtained in the laboratories of McGill University. Means of independently varying the E.M.F. on feeders were then discussed and the Stillwell regulator described. Compounding of alternators for non-inductive load was then described, as also the recent composite wound revolving field alternator of the General Electric Co., which compensates for inductive as well as for non-inductive loads. The exciter armature is placed on the same shaft with the generator fields. A.C. current taken from series transformers placed in the line is passed into the exciter armature by means of suitable slip rings setting up a rotary magnetic field of the same period, but opposite in direction to the rotation of armature, thereby producing stationary poles in space. When an inductive load is put on the generator, the resulting lagging current has the effect of shifting these poles in such a manner as to increase the induction through the whole armature, thus raising the E.M.F. of the exciter and consequently the main generator E.M.F. Station devices, for indicating the E.M.F. at the end of the line, were then considered, and the Mershon compensator described, which allows for the inductive as well as the ohmic drop in the line. The difficulties of parallel operation of alternators, when driven by steam engines, were pointed out. The regulation and output of alternating current machinery, as effected by the power factor of the load, was then fully discussed and explained by means of suitable diagrams. The connection of several typical systems, 3-phase, 2-phase, mono-cyclic, etc., was also shown.

The next lecture, it was stated, would deal with methods of handling high tension currents, high tension transformers and the methods of line calculation.

A vote of thanks was extended to Professor Owens for his lecture.

The Civil Engineers' Club of Toronto held its regular monthly meeting at the Rossin House on the evening of the 7th ult. The following were present: Messrs. Canniff, Chewett, Chipman, Clement, Duff, Galbraith, Hanning, Hertzberg, Jennings, Smith, Speight, Spry, Stewart, Temple, Tully and VanNostrand. The topic of discussion for the evening was "The Necessity for a Topographic Survey of Canada." A congratulatory address to the Canadian Institute was adopted, the Institute having now been in existence fifty years. The trunk sewer problem will be discussed at the next meeting.

THE ROBERTSON CATCH BASIN.

Imitation is said to be the most sincere form of flattery, but when it goes as far as infringing on a patent it is time to call a halt. The deserved popularity of the G. A. Robertson catch basin tempted a foundryman in a western town to make up some catch basins on the exact lines of the Robertson, but without the trap feature, which is of vital importance. Steps have been taken to prevent a repetition of this illegal action, and the patentees wish to warn anyone else from following a similar course. The Robertson basin's reputation is steadily increasing, and quite a number of municipalities are adopting this basin for their sewage system. Among orders recently received are, Delorimier, Outremont and Montreal Junction.

COKE FROM NOVA SCOTIA COAL FOR USE ON RAILWAYS.

Numerous experiments have been made with the coke manufactured in Halifax by the People's Heat and Light Company as a locomotive fuel on the Intercolonial Railway. Lucious Tuttle, president of the Boston and Maine Railway, speaking of the introduction of similar coke on that railway system, says: "Coke as produced by the New England Gas and Coke Company, is a perfect locomotive fuel, and we are changing over our locomotive equipment so as to adapt same to the burning of coke as rapidly as we can get engines into the shops. This process is naturally slow at this season of the year, when every engine is in use. We expect to have 50 locomotives changed over this summer and 100 before next January, unless some new conditions arise which we do not anticipate. We already have about a dozen changed over and are using most of them in our suburban service between Boston, Gloucester and Marblehead. We have one on our through Portland express, and it is fulfilling all our expectations. It costs about $50 to change over an engine by placing in water grates, which we find best adapted for the purpose. The coke creates such an intense heat that cast-iron grates are not serviceable. By building up our engine tenders we are able to run our engines from 125 and 150 miles without refueling, and we cannot do better than this with coal. Of course the great advantage in the use of coke is that it is dustless and smokeless. On the run from Boston to Portland there will hardly remain a handful of ashes, whereas, in the burning of coal almost three bushels of ashes would remain. The cost of coke is just about the same as bituminous coal, while the advantages are innumerable. Through the oiling of our roadbed and the burning of coke we will be able to give a passenger service as clean as electric roads. We estimate that the Boston and Maine will effect a saving of at least $100,000 a year that it now pays in damages by reason of fires from sparks. Coke as a locomotive fuel is only made possible through Mr. Whitney, for he sells coke as a by-product. If coal was turned into coke simply for the coke the cost would make its use prohibitive. The use of coke is just as economical for freight engines as for passenger, and when we can get to it, it will be used on both freight and passenger engines. The engineers and firemen much prefer it to coal, and understand its use. Bituminous coal requires constant firing, whereas coke only requires refiring about every twelve miles."

LITERARY NOTES.

The Locomotive Fireman's Magazine for November has a portrait of the Queen and a number of excellent views relating to the South African war.

The Canadian Magazine has issued a December number of unusual excellence. The front cover, "The Golden West," is the finest that has ever appeared on a Canadian publication.

The Street Railway Journal's convention number (October) contains 156 pages of reading matter, 284 pages of advertisements and each copy weighs 4 lbs. 10 oz. Our enterprising New York contemporary bulks large in the eyes of its readers.

The Prince Edward Island Magazine, Charlottetown, has in its November issue a very clear photo-engraving of the P.E.I. contingent for South Africa, and a very fine looking squad of men the islanders are. This magazine continues its interesting sketches of P.E.I. history.

The Use of the Slide Rule is a pocket sized volume, cloth bound, by F. A. Halsey, associate editor of The American Machinist. It contains a hundred pages of valuable advice and suggestions, and is well illustrated. D. Van Nostrand Co., New York.

Everyone who has ever planned a house or ever intends to do so, and these classes include all mankind, will take a great interest in Keith's Architectural Studies. The Moderate Cost Houses in Vol. 2 range from $800 to $1,200. W. J. Keith, architect, Minneapolis, Minn.

"The Methodist Churches of Toronto" is the title of a substantial volume illustrating and describing the growth of the Methodist churches of the Ontario capital, starting from the days of Governor Simcoe, and carrying the story down to the present day. The work is dedicated to Rev. Dr. Briggs, whose ability and integrity as steward of the Methodist Book room for many years have been so well recognized, and it contains in addition to 19 engravings of the 36 churches in Toronto, short biographical sketches of well known Methodists to the number of about 300. The editor and compiler is Thomas E. Champion, author of the "History of the Royal Grenadiers," the "Anglican Church in Canada," and other works, besides many valuable contributions to our magazine literature. The present work will be an instructive contribution to the already respectable bulk of Canadian Methodist literature.

The contributors to the December Ladies' Home Journal include Finley Peter Dunne (author of "Mr. Dooley"), Rev. Cyrus Townsend Brady, Ian Maclaren, S. T. Pickard, Mrs. Burton Kingsland, Edward Bok, George W. Cable, Albert W. Smith, Dan Beard, Franklin Fyles, Sara Beaumont Kennedy, and a half-score of other equally well-known writers. To the pictorial embellishment of the same number A. B. Frost, W. L. Taylor, H. C. Christy, Frank O. Small, Walter Russell, Lucius Hitchcock, and others have contributed their best efforts. The Christmas Journal covers an unusually wide field of interest. The great festal day is the theme of carol, story and pictures, and of various practical, useful articles, while numerous topics that are uppermost in the minds of women and helpful in the conduct of the home, are practically discussed. By The Curtis Publishing Company, Philadelphia. One dollar a year; ten cents a copy.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.

The monthly educational meeting of the Hamilton branch of the C.A.S.E. was held on Tuesday evening, November 21st. The increased attendance was such as to assure the officers of the success of their experiment in devoting one meeting a month to educational topics, and the indications are that all interested in mechanics and engineering will take advantage of these meetings during the coming winter. The subject of the first paper was "Powers of Numbers, and Square and Cube Root," being one of a series on Mathematics, given by C. R. T. Fessenden, of the Westinghouse Company. The fact was emphasized that an essential qualification of the modern engineer was the ability to calculate areas and cubic contents, and to do this it was necessary that he have a knowledge of square and cube root. Mr. Fessenden gave rules for measuring and obtaining areas of circles, squares, triangles, irregular figures, etc., and in answer to a question explained the method of calculating the difference between a square and circular inch. A hearty vote of thanks was tendered Mr. Fessenden. A feature of the meeting was the distribution of a leaflet on "Fractions and Decimals," the first of a series being issued by the Ontario Executive on educational topics. The next meeting of this nature will be held on December 19th, and an invitation to attend has been extended through the local papers to all interested in mechanics, engineering, electricity, etc.

WATERMAIN SCRAPING.

The pipe cleaning operation was resumed last summer by the city engineer of St. John, N.B., with almost the same apparatus as in the preceding year. After carefully studying the action of the cleaner, and giving it several runs it was found that an improvement could be made in the scraper, which was accordingly done, and each arm fitted with a steel cutter which would not clog. It was also found that the arms could be stiffened without any risk of the machine sticking, and this was accordingly done. This scraper cut through all the deposit and right into the bare iron, an inspection at the termination of the work having shown that only the scars or imprints of tubercles remained on the interior surface of the pipe, and it was almost as smooth as when first made. The whole amount of the material removed was not measured, as the flushing branches delivered into the brooks, and the supply of water having been abundant the dirt was generally carried off in liquid form. An estimate may be had by bearing in mind that the average thickness of the deposit was fully three-quarters of an inch and the length of the main 23,000 feet. It will thus be seen that about 335

cubic yards were removed. In the Marsh Creek at the terminal flushing pipe, quite an extensive bar was formed by the material discharged from the main, and the current carried a large quantity away. When flushing into Little River by means of three different branches within one mile of Silver Falls the water of the falls assumed the color of strong coffee, and Major's Brook looked like ink at its confluence with the Marsh Creek, though it had received the flushings of the main 7,500 feet further up. These facts are given to show the impossibility of measuring the quantity of material taken out of the pipe. At No. 3 Hatch Box, where the cleaner had been taken out fifteen times when cleaning the upper end of the main, 108 bushels of heavy material, which would not flow off by the drain, remained, and had to be taken up in buckets as it accumulated, but all the more pulverulent scrapings were carried off in the drain, and as stated, blackened the water of the brook upwards of a mile away. At the other hatch boxes where the current was much stronger, an aggregate of 44 bushels of heavy material had to be hoisted out. The improvement in pressure ascertained in the same manner as at the end of the 1897 cleaning, viz., by sending the whole city's supply through Nos. 1 and 2 and leaving No. 3 shut off during the test, amounted to eleven feet. That is to say, that the two pipes, whose combined capacity before the cleaning began was only equal to that of raising the water 80 feet, can at the present time supply the whole district and deliver up to a level of 141 feet above high water datum in the harbor.

The lightness of the cleaner is a great advantage, the entire weight being but 263 pounds, and the bulky portion being made of wood, which weighs less than the water itself, it floated along with the water. This quality was well exemplified when the broken portion was taken from the main as related in last annual report. The hatch boxes were of cast iron, consisting of a section of pipe with the upper half removable and secured in place by means of screw bolts and nuts, the flanges being gasketed with Tuck's 1¼-inch round packing, which adapted itself to all the inequalities of the casting and to the curved form of the flange. Each one weighed about 3,300 pounds, and required 26 square necked bolts, besides about 18 feet of Tuck's packing. On completing each one, the pit was walled up with dry rubble and covered with timber, outside the city. Inside the city the covering was arched in masonry and cement, and an iron manhole left in the crown; the manhole being large enough to pass the cleaner through. The force employed to operate the cleaner consisted of a foreman, a mechanic, two watchers, six assistants and two express teams and drivers.

FIRES OF THE MONTH.

Nov. 2nd. Murray's planing mill, Winnipeg, Man.; damages, $12,000.——Nov. 3. The barrelling department of the Sun Oil Co., Hamilton, Ont.; loss, $6,000.——Nov. 4. Ontario Power & Flats Co., Toronto; the damages amounted to $17,000, divided among W. Spanner & Co., Gilchrist & Co. and Fraser & Co., woodworkers.——Nov. 5th. Webster & Boyes' carriage factory, Napanee; loss about $1,600.——Nov. 5th. D. I. Hamlin's evaporator, Port Hope, Ont.; loss, $4,000.——Nov. 9th. MacNeil's sawmill, West Devon, P.E.I., wholly destroyed.——Nov. 10th. T. Peters, tannery, St. John, N.B.; damages, $40,000.——Nov. 12th. Viau & Bro. biscuit and candy factory, Montreal; loss, $300,000.——Nov. 15th. W. W. Gordon's planing mill, Glencoe, Ont.; total loss.——Nov. 22nd. R. T. Houston's sash factory, Tweed, Ont.; loss from $6,000 to $8,000.——Dilworth's elevator, High Bluff, N.W.T.; insurance, $12,000.

THE PRACTICAL MAN.

STANDARDS OF LENGTH.

The standard yard was first legalized in England, in 1824; this standard, however, was destroyed in 1834. The standard imperial yard "Bronze No. 1," was then prepared and legalized in 1855. Forty copies were made, and one of these, "Bronze No. 11," was presented to the United States by the British Government in 1856. At the same time another copy, known as the Low Moor Iron No. 57, was sent. These were accurately compared, before being sent, with the standard imperial yard, and the record of the variations sent with them. Although the Constitution of the United States empowered Congress to fix the standards of weights and measures, no legal standard of length was adopted until 1866, when a law was passed making the metre legal, the first and only measure of length legalized by the United States Government.

METRIC MEASURES.

The metric unit of length is the metre = 39.37 inches.

The metric unit of weight is the gramme = 15.432 grains.

The following prefixes are used for subdivisions and multiples: Milli = 1/1,000, Centi = 1/100, Deci = 1/10, Deca = 10, Hecto = 100, Kilo = 1,000, Myria = 10,000.

METRIC AND BRITISH EQUIVALENT MEASURES.

MEASURES OF LENGTH.

French.	British.
1 Metre	= 39.37 in., or 3.28083 ft., or 1.09361 yds.
.3048 Metre	= 1 foot.
1 Centimetre	= .3937 inch.
2.54 Centimetres	= 1 inch.
1 Millimetre	= .03937 inch, or 1-25 inch nearly.
25.4 Millimetres	= 1 inch.
1 Kilometre	= 1093.61 yards, or 0.62137 mile

MEASURES OF WEIGHT.

French.	British.
1 Gramme	= 15.432 grains.
.0648 Gramme	= 1 grain.
28.35 Grammes	= 1 ounce Avoirdupois.
1 Kilogramme	= 2.2046 pounds.
.4536 Kilogrammes	= 1 pound.
1 Tonne or Metricton, 1000 Kilogrammes	= .9842 ton of 2,240 pounds, 19.68 cwts., 2,204.6 pounds.
1.016 Metric tons, 1016 Kilogrammes	= 1 ton of 2,240 pounds.

MEASURES OF CAPACITY.

French.	British.
1 Litre (= 1 cubic Decimetre)	= 61.023 cu. in., .03531 cu. ft., .2642 gal., 2.202 pounds of water at 62° F
28.317 Litres	= 1 cubic foot.
4.543 Litres	= 1 gallon, Imperial.
3.785 Litres	= 1 gallon.

NEW CATALOGUES.

We have received Catalogue 64 of the Sprague Electric Co., which discusses Lundell Generators, direct connected and better types, from the Canadian agents of this company, Jack & Robertson, Montreal.

The Dodge Mnfg. Co., Toronto, Ltd., is sending out a catalogue illustrating a full line of power transmission machinery. This is a work of some 270 pages, and should be found very useful to superintendents of mills and factories, also to mill architects and mechanical engineers. The work not only illustrates and describes fully and completely transmission machinery, but it also provides complete dimension tables covering each line; so that work may be provided for and laid out accurately from the beginning. We think the Dodge Co. is to be congratulated upon the volume. The Dodge Co. makes a specialty of shafting, hangers, pulleys, friction clutch pulleys, friction couplings, self-oiling bearings, belt tighteners, rope driving, chain and sprockets, jack shaft equipments, etc.

The B. Greening Wire Co., of Hamilton, has just issued a catalogue on "Wire Rope" as the first of a series of special catalogues to be sent out soon. Besides being a price-list of all kinds of wire rope, it gives particulars of fixtures and appliances to be used with wire rope, and what we think a great many regard as most useful, a number of valuable tables as to the working, etc., of wire rope under different conditions. Inside the front cover is a telegraphic code to be used when ordering, and on the back of the book is a cut of the works showing the new power loom mill just erected. This catalogue will be followed by one of Wire Cloth and Perforated Metals, which is now in the press. The company will send any of these catalogues to readers of The Canadian Engineer, if they will say what department they are particularly interested in.

The Canadian Heine Safety Boiler Co. have sent us the eighth edition of their publication, called "Helios." It is a handsomely bound volume of nearly 200 pages, and besides giving a full description of the Heine boiler, also contains much information of a valuable nature from the pens of eminent writers regarding fuels, steam engines, and a number of tables and data for reference. Professional men, manufacturers and practical steam engineers will find it invaluable.

Machinists' tools and measuring tools describes the contents of Brown & Sharpe Manufacturing Co.'s new 140 page catalogue. It contains also much valuable information, such as reference tables, etc. It is beautifully illustrated, and no catalogue that has ever passed through our hands is more worthy of a place in the kit of the machinist or on the shelf of the buyer of fine tools. Many new lines have been added since their last issue of a general catalogue. In writing for this catalogue ask for No. 101.

Industrial Notes.

A new sawmill is to be built at Watford, Ont.

The Hamilton Distillery Co. has installed the Redpath-Reid automatic smoke consumers in its works.

A large brickyard is proposed at Orangedale, C.B., and it is said that the necessary site has been secured.

The Ontario Lantern Co., Hamilton, Ont., is building an addition to its works, 98 x 38 feet, three stories high.

The debentures for a new waterworks system at Calgary, N.W.T., have been signed and a contract will be let at once.

The city engineer of Toronto urges the city council to buy additional pumping plant to the extent of a ten million gallon pump.

John Duffy, St. John, N.B., has been awarded the contract for building a quarantine station at St. John, the price being $18,500.

Smith's Falls, Ont., has given C. T. Hookway, Syracuse, N.Y., the contract to build a trunk sewer in that town. The contract price is $17,590.

The new grist mill now in course of construction at Gagetown, N.B., will be owned and worked by J. H. Brown & Son, formerly of Apohaqui, Kings county.

G. P. Magann and Alex. Fraser, Toronto, and E. J. Fawke, and others, have been incorporated as the Magann, Fawke Lumber Co., Ltd.; chief place of business, Toronto; capital, $300,000.

R. H. McKee and T. H. Wright, J. A. Macrae, McLeod Stewart, Ottawa, and A. M. Perkins, Perkins Mills, Quebec, have been incorporated as the McKee Machinery and Lumber Company, Ltd.

T. J. Drummond, G. E. Drummond, J. T. McCall, C. E. Gudewell, C.E., Montreal; F. Thompson, Sherbrooke, Que.; G. Gudewell, New York, U.S., have been incorporated as the Lennoxville Waterworks; capital, $50,000.

J. McBurney, J. T. Beattie and T. A. Rowan, Toronto; and J. A. Coulter and Rebecca M. Morrow, Ingersoll, Ont., have been incorporated as the McBurney, Beattie Company, Ltd.; chief place of business, Toronto; capital, $40,000.

The International Correspondence Schools, of Scranton, Pa., offer special privileges in the way of reductions in the price of books and technical outfits to all students who enroll before January 1st, 1900. Circulars, defining these privileges, will be sent on application.

The Goldie & McCulloch Co., Ltd., Galt, Ont., is very busy, and during the week ending November 25, shipped several large safes and three car-loads of flour mill machinery to different parts of the Northwest Territories; one car-load of same to Lucan, one car-load of boilers, etc., to Hamilton, two gas engines, and several minor shipments.

The employees of the Jas. Warnock & Co., with the members of the firm, banqueted together in Polson's Hall, Galt. Many of the men had been employed for over a score of years by this concern; a total of 355 years was the record claimed by thirteen employees. F. H. Hayhurst, the manager, in his address, referred to the fact that for over a year night work was necessary to keep up to their orders.

Harriston, Ont., has voted a bonus of $20,000 to the Harriston Pork Packing Co.

The Cornwallis Valley Packing Co., Kentville, N.S., has been incorporated; capital, $30,000.

The removal of the Canadian Locomotive and Engine Co. from Kingston, discussed so often, is again talked of. The city council has not agreed to the $50,000 bonus asked.

F. W. Thompson, western manager of the Ogilvie Milling Co., reports that a Canadian foundry will put in a plant at Fort William, Ont.

The Toronto Electric Light Co. has equipped its new Heine boilers with the Jubilee shaking grate bars, each boiler requiring 60 sq. ft. of grate.

The plant of the Berlin, Ont., Rubber Co. was given a test on Nov. 16th. The special machinery was supplied by the Birmingham Foundry Co., Derby, Conn.

Application has been made by the Dominion Oil Pipe Line Co., Sarnia, Ont., for the reduction of the capital stock to $500,000, and to change the headquarters of the company to Toronto.

L. Page, liquid glue maker, is at the head of a company which is erecting a factory on Howe Sound, B.C., for the manufacture of glue and oil from the dog fish. R. J. Leckie, Toronto, is a member of the company.

A. O. Norton, Coaticook, Quebec, manufacturer of ball bearing lifting jacks, has added additional machinery to his plant, to keep up with the increasing demand for his product. He reports several large export orders received last month.

It is reported that the agricultural and implement works of Frost & Wood, Smith's Falls, Ont., are to be doubled in capacity next spring. A single English order recently received by this firm was for a thousand machines of the same kind.

The Canadian Rubber Co., Montreal, has placed contracts for a warehouse of large dimensions in that city. It is intended that the establishment will be 180 x 170 feet, occupying the entire block which faces Craig, St. Adolphe, Notre Dame streets and Papineau square.

In our advertising pages, E. Leonard & Sons, engineers, London, Ont., announce a new type of engine. This is a self-oiling automatic engine, adapted for either electrical or manufacturing purposes. We understand the firm will send a descriptive catalogue on application.

W. Currie, F. P. Currie, J. T. Shearer, Hon. J. A. Ouimet, J. Livingstone, Montreal, and T. E. Fee and E. S. Fee, St. Hyacinth, Que., have been incorporated as the Dufferin Falls Lumber, Pulp and Paper Company of Montreal, with a capital of $1,000,000; chief place of business, Montreal.

C. R. Whitehead has been re-elected president of the Montmorency Cotton Mills Co., of Montmorency Falls, Que. The company now employs 550 hands, and proposes to build a new mill next year to be devoted to the export trade. The new mill will ship cotton goods, chiefly to China and East Africa.

H. Pearce, Birmingham, Eng., H. Pearce, jr., Montreal; J. F. Beringer, T. E. Owens and Francis, Picton, Ont., have been incorporated as the Bloomfield Packing Co., Ltd.; chief place of business, Picton, Ont.; capital, $40,000.

Redpath-Reid automatic smoke consumers have been installed in the following plants among others: Mitchell Waterworks and Electric plant, Mitchell; American Rattan Co., Walkerton, Canadian Colored Cotton Mills, Hamilton; George Pattinson & Co., Preston; Lambton Woolen Mills, Lambton; Canadian Colored Cotton Mills, Merritton; Brighton Canning Co., Brighton, Ont., and Central Ontario Railway Co.

The Canada Foundry Co., which was incorporated last month with a capital of $1,000,000, has bought the St. Lawrence Foundry, Toronto, from the Rice Lewis Co., Ltd., to serve as a centre, about which will be built up the vast business in iron castings, especially for architectural work, which the company announces it will undertake. The first directors of the company are: E. B. Osler, W. R. Brock, W. D. Matthews, Toronto; Wm Hendrie, Hamilton, Ont.; F. Nicholls, T. W. Horn, Toronto and W. H. Winslow, of Winslow Bros., Chicago, who are said to be the largest architectural iron workers on the continent

A bonus of $50,000 has been voted to the proposed steel shipbuilding company at Collingwood, Ont.

The Brantford, Ont., Co-operative Pork-Packing Co. has bought a site on which to build its factory.

Robt. Lillie, foundryman, Perth, Ont., has sold out to James Bros. The new firm will make and repair ploughs, stoves, etc. The foundry will be managed by F. Deacon.

Sproatt & Rolph, architects, Toronto, have let the contract for installation of blast system of heating, also the plumbing of the Lever Co.'s soap factory, Toronto, to W. J. Maguire & Co., Toronto.

Early in January McGill University will open a new course of instruction for graduates in medicine in Public Health. Such a step as this is most encouraging to those whose aim is the improvement of sanitary conditions.

The Chalcraft Screw Co., of Brantford, capital $75,000, has been incorporated with the following provisional directors: E. Chalcraft, F. Chalcraft, E. L. Goold and C. Cook, Brantford, Ont., and George Randall, Waterloo, Ont.

The Department of Railways and Canals, Ottawa, is calling for tenders for constructing an additional section of the Trent canal, viz., that from Trenton to Frankton, a distance of nine miles. The work includes the deepening of the Trent river, between these two points, the construction of seven locks and seven dams.

The industries of Hamilton are steadily progressing. Among other extensions the firm of J. N. Tallman & Sons, successors to Wm. Hunter in the well known brass founding business, are now erecting an addition to their works which, when completed, will make it one of the largest and best equipped brass foundries in Canada. Among the specialties of the firm are phosphor-bronze, zinc, copper and aluminum, bronze castings, and anti-friction metals.

In the presence of a large number of the citizens Mayor Wilson formally opened the new buildings of the Victoria Hospital at London, Ont. A massive gold key was presented to the mayor by Thos. Gillean, jeweler, and the same gentleman also presented the hospital with a magnificent solid silver tea service. The architecture is colonial, and the architect, H. C. McBride, of London, was complimented highly on the results of his work. The buildings will cost completed about $100,000, and a saving of at least 25 per cent. was effected by letting contracts, and getting the building started last year before the rise in material took place.

At the national convention of ice manufacturers at Indianapolis, Ind., last summer, while the question of the best method of filtering was being discussed, one of the leading manufacturers made the statement that he had tried every scheme of which he had ever heard for cleansing distilled water from oil without satisfactory results, until about a year ago, when he put in an Austin Oil Separator, manufactured by the Austin Separator Co., Detroit, Mich. Since that time he has had absolutely no trouble, and has secured perfectly clear ice. As he used water distilled from exhaust steam, his experience will go far to clear up the problems which confront so many engineers who use exhaust steam, and have the troubles consequent to feeding oil in the boiler, or steam pipes where exhaust is used for heating. The Austin steam separator is also said to do equally good work in eliminating moisture from live steam.

Owing to the increase in its output the Atlantic Refining Co., Toronto, has decided that more central and commodious quarters are required. The company has leased for a term of years the premises formerly occupied by the Toronto Carpet Co. on the Esplanade at the foot of Jarvis street, and with the improved facilities for shipment, either by water or rail they will be in a much better condition for handling shipments. The Atlantic Refining Co. claims that its position in the oil trade is unique; it prides itself on being a thoroughly independent concern, outside of the combine, and its specialty is the supplying of lubricating oils made from Pennsylvania crude, and it is generally acknowledged that for the best grades of cylinder oil Canadian crude oil will not answer, the Pennsylvania stock being unrivalled for this purpose. The Atlantic Refining Co. will, in our advertising columns, deal more fully with its different wares.

Berlin, Ont., sewage disposal works are threatened by neighboring farmers with legal proceedings on account of offensive odors arising from the beds.

There having been granted $30,000 for the rebuilding of the interprovincial bridge at Portage du Fort, Que., $20,000 from the Federal Government and $5,000 each from the Ontario and Quebec Governments, work upon the new bridge is now going on

The largest contract for pipe and boiler covering given in Canada is said to be that just awarded by the Lady Superior of the Longue Pointe Asylum, Montreal, to the Clappison Pipe and Boiler Covering Co., of Hamilton, and now being filled under the supervision of J. H. Clappison of that firm. The main building is 3,000 feet long with several wings, and it will take a month to instal and complete the heating apparatus.

The offices and warehouse of the Fairbanks Co., Craig street, Montreal, are a model of order and attractive display. The show cases of machinists' tools, valves and special mechanical appliances strike the eye at once, and there are many novelties to interest the visitor. Some of these specialties of the Fairbanks Co. have been described in previous numbers, but the engineer and machinist visiting Montreal will find in the five stories of this warehouse many other things that will instruct them.

Another failure to be added to the list of bonus-hunters, is that of N. Commire, Fils & Co., foundrymen, in Maisonneuve, a suburb of Montreal. Mr. Commire was long in business in Montreal without achieving any very material success, and in 1896 moved to St. Jerome, under a bonus arrangement from that town. He remained there but a short time, and moved to Maisonneuve two years ago, making a new arrangement with the latter town. A demand of assignment has now been made upon the firm.—Monetary Times.

Electric Flashes.

Seamen, Kent & Co., Toronto, are installing a 60 light dynamo in their factory from the works of the Jones & Moore Electric Co.

The Canadian General Electric Co. is installing an electric lighting plant of 150 light capacity for the Georgian Bay Cement Co., Owen Sound, Ont.

Jno. Penman, Esq., Paris, Ont., is installing a model electric plant for the lighting of his residence, purchased from the Canadian General Electric Co.

The Canadian General Electric Co. have closed a contract with the Imperial Oil Co., Sarnia, Ont., for a standard 40 k.w. direct current generator, direct connected to Ideal engine.

C. M. B. Lawrence, proprietor of the Oakville, Ont., Electric Light Co., has purchased from the Canadian General Electric Co. a standard single phase alternator of 1,000 light capacity.

The Canadian General Electric Co. has received an order from the Acadia Edison Co., Wolfville, N.S., for two standard 25-k.w. multipolar direct current generators with switchboards, etc., complete.

New Westminster, B.C., has contracted with the Canadian General Electric Co. for a standard 150-k.w. monocyclic generator with switchboard, etc., for the supply of light and power throughout the city of New Westminster.

Wm. Kennedy & Sons, Ltd., Owen Sound, Ont., have purchased a 500 light electric plant from the Canadian General Electric Co., consisting of a latest type, Form H., multipolar generator with marble panel switchboard and wiring material for their works throughout.

The Nelson Electric Tramway Co., Nelson, B.C., has placed an order with the Canadian General Electric Co. for its entire requirements electrically, consisting of one standard 325-k.w. railway generator with panels, one 500 h.p. three-phase revolving field synchronous motor with panels, together with full complement of cars and motors. They have also contracted with the West Kootenay Power and Light Co., Rossland, B.C., for the power necessary to operate this plant

The Nova Scotia Carriage Co. has purchased a 100 light dynamo from the Jones & Moore Electric Co.

D. G. Whiddon, Antigonish, N.S., has placed an order with the Canadian General Electric Co. for a 500 light direct current plant.

The Jones & Moore Electric Co. shipped five motors to Vancouver, B.C., during the month, and find difficulty in filling their orders. The demand is much in advance of former years.

The plans for the new electric plant for the Toronto Rubber Shoe Mnfg. Co., at Port Dalhousie, Ont., were prepared by R. J. Parke, consulting electrician, Toronto.

The terms offered by the Niagara Falls Park Commissioners for the privilege of constructing an electric railway along the Niagara river have been rejected by the Fort Erie Electric Railway Company, and an alternative proposition is being considered

The Dartmouth Electric Light Co., Dartmouth, N.S., has placed an order with the Canadian General Electric Co. for a standard 30-k.w. single phase alternator with switchboard transformers and wiring complete.

The Canadian General Electric Co. is installing a standard 120 k.w. single phase alternator for A. Gagnon & Co., Victoriaville, Que. This is the second machine of this size and type which this company has installed during the past year.

The Montmorency Electric Power Co. is suing the Jacques Cartier Electric Light and Power Co. for $25,000 damages, and for an injunction restraining it from doing business in the city of Quebec, for which the complainants claim the sole right to supply electricity.

While repairing wires in the factory of the Union Carbide Co., Niagara Falls, N.Y., Nov. 25th, John Sheffield was instantly killed by coming in contact with the primary terminals of a switch, where he received a shock from a current of 2,000 volts. He was a scholarship man in electrical engineering.

The Dominion Iron and Steel Co. has placed an order with the Robb Engineering Co. for two 150-h.p. engines for electric lighting purposes. They have also recently bought from the Robb Co. a number of smaller engines and boilers for temporary use during the erection of their extensive plant.

Hon. F. Peters, ex-Premier of Prince Edward Island, and E. J. Fader, Vancouver, B.C., propose to turn to account the power of the tide in both the first and second narrows in Vancouver harbor, to operate an electric plant. They have applied to the Dominion Government for certain foreshore rights to enable them to proceed in the matter.

R. A. Ross, consulting electrical engineer, Montreal, has just returned from a professional tour through China, Japan, British India, and other eastern countries. He reports the electrical development of Japan as very complete, and the entire work in the hands of the natives who have been trained abroad. Mr. Ross states that a wave of electrical progress swept over India about a year and a half ago, and tramways are now to be seen in Calcutta, Bombay, Colombo and Madras, which are quite well equipped.

A meeting of the Toronto Street Railway Electrical and Mechanical Association was held last month, which was composed of representatives from all the different mechanical and electrical departments of the railway. The finances of the benefit fund were reported by Secretary Cox to be in a flourishing condition, and the sick and distressed members of the society have been well cared for. The following officers were elected: President, G. J. McCullough, chief electrician of the railway; vice-president, M. Power; secretary, William Cox; treasurer, R. Bunting.

The Canadian General Electric Co. has just received an order from the Trenton Electric Co. for a 75 light equipment of alternating series enclosed arc lamps, with automatic regulating transformers and switchboards. These are to be used for street lighting in Belleville, Ont., the current being taken from the three-phase transmission lines, coming from Trenton a distance of 13 miles. This is the third installation of this kind which is being put in in Canada; a 100-light capacity equipment having been installed in Sherbrooke, Que., and another 100 lights in Halifax, N.S., both of which are, it is said, giving eminent satisfaction

The St. Catharines Cold Storage Co. have installed a 20 h.p. motor of the Jones & Moore Electric Co.'s make.

The Jones & Moore Electric Co. shipped eight motors to the Winnipeg Street Railway Co. during the last month.

The Patent Exchange and Investment Company, on behalf of B. R. Dodge, Post Mills, Vt., U.S., inventor of the Dodge system of telephony, has applied for a charter to put in a telephone system in Toronto. The city engineer will report upon the scheme.

The second electric locomotive in Canada has been put in service on the Metropolitan Ry., Toronto. The locomotive was manufactured at the Baldwin works, Philadelphia, and weighs when completely equipped nearly 50 tons. The power of draught of one of these engines is fully equal to a large mogul engine, and a guarantee accompanies it that it is capable of drawing a 30-ton car up a grade of 9 in 100.

Port Dalhousie is to be electrically lighted from a plant now being put into the Toronto Rubber Shoe Mnfg. Co.'s works there. The machinery, which is supplied by the Royal Electric Co., provides for 10 arc lamps and 500 incandescent lamps for the village, and 20 arc and 600 incandescent lamps for the factory. There will also be a 10 h.p. motor for the elevator, and a 15 h.p. motor to drive the machinery in the factory, besides a 20 h.p. motor for the heating and ventilating plant.

Ahearn & Soper, electrical engineers, Ottawa, have orders for motors to the aggregate of 4,000 h.p. for the Dominion Cotton Mills Co.'s two mills in Montreal. These are of the Westinghouse induction type, and form the most complete and extensive electrical equipment of any cotton mill in the world. Among other electrical installations by this firm in Montreal are a 100 h.p. motor for the Dominion Oil Cloth Co.'s new factory; a motor for P. Lyall's marble works, and three motors for the Wire and Cable Co.'s new works in Beaver Hall Hill.

The Massey-Harris Co., Ltd., has decided to equip its Toronto factories with a modern system of electricity for light, heat and power. They have contracted with the Canadian General Electric Co. for two 100-k.w. direct current generators direct connected to Ideal engines; in conjunction with these they are installing generator and feeder panels, arranged for controlling the system of lighting throughout all the different departments. This plant will be one of the largest isolated installations in Canada.

The Electrical Maintenance and Construction Co., of Toronto, Ltd., which began business less than a year ago, under the management of P. H. Patriarche, has had a remarkably successful career, the business having expanded till it has now contracts in hand aggregating over $100,000. In view of the development of its business it has been found necessary to increase the capital stock from $20,000 to $250,000. Mr. Patriarche was with the Toronto Electric Light Co. for some time, in which connection he gained the knowledge which has enabled him to organize and rapidly extend the business of the new company. One of the contracts this company now has in hand is the Orillia power plant, which will be referred to in another issue.

Incorporation has been granted to the Lake Simcoe Navigation Company, Ltd., capitalized at $90,000. Among the incorporators are, J. C. McKeggie, J. McNairn, Edward Adamson and Wm. Paul, Toronto, and J. L. Ross, Aurora, Ont.

—The Royal Electric Co., Montreal, is installing in the head office of the Merchants' Bank of Canada, Montreal, two 50-k.w. direct connected generators with Robb-Armstrong engine complete with switchboards. These generators are to operate at 250 volts, and the building is wired for lighting to operate lamps at 220 volts, and also two Sprague elevators.

The Rideau Navigation Co. is having a passenger boat built by the Davis Dry Dock Co., Kingston, Ont. It is 112 feet by 28 feet, and draught 7 feet. The upper cabin is to be 84 feet long, and will contain 32 staterooms. The engines are triple expansion, 8½, 13, 21 and 14 inch stroke. A speed of 12½ miles is guaranteed. The cost will be $20,000. The Davis Dry Dock Co. is also rebuilding the steamer "Constance," of Gravenhurst, Ont., at a cost of $3,500.

Railway Matters.

The Railway Committee of the Privy Council has ordered a subway to be built at the Lansdowne avenue C.P.R. crossing in Toronto. The cost will be about $30,000, to be borne equally by the city and the railway.

Officers of the Morris, Portage and Midland railway, a projected line for which a charter has been issued, were elected in Winnipeg as follows: J. W. Kastner, president; G. F. Birney, Morris, treasurer, and G. A. Glines, Winnipeg, secretary.

It is stated that according to present plans of the C.P.R. the old freight sheds near the Queen's wharf, Toronto, will be converted into car shops. These extend from the garrison bridge east to Bathurst street, and are the old Toronto, Grey & Bruce depot. The new workshops will employ about 150 hands.

Judgment has been given in the case of Beemer vs. the Pontiac & Pacific Junction Railway Company. This was a claim for $400,494.21, representing $342,903.47, amount of a claim transferred to plaintiff by F. Ross representing the estate Ross, and also $57,590.74, amount due by defendant to plaintiff for cash advances. The defendant did not appear, and judgment was rendered in favor of plaintiff by default.

Efforts are being made to have the Kingston & Pembroke railway extended into the mineral belt of Quebec in the vicinity of Bryson, which now cannot be developed for lack of transportation. Twelve miles of track from the Kingston & Pembroke railway terminus at Renfrew would bring the line to Portage du Fort, and eight miles' further extension would bring it to Bryson, the county town of Pontiac.

Iron and Steel.

Rhodes, Curry & Co., Ltd., Amherst, N.S., will, it is said, build workshops in Sydney, C.B.

It is stated that local capitalists propose to put $100,000 into manufacturing saws in Hull, Que. It is the intention of the syndicate to work in conjunction with the Ottawa Saw Works.

The Abbott-Mitchell Iron & Steel Co.'s new works at Belleville, mentioned in previous numbers, will be in operation in a few days and will be perhaps the most modern plant of its class in Canada.

F. R. F. Brown, consulting engineer, has been appointed secretary of the board of directors of the Dominion Iron and Steel Company, of Sydney, C.B. He will represent the company in Montreal.

Merrickville, Ont., is negotiating with the Canadian Engine and Locomotive Works, Kingston, for their removal to that town. It is reported that a bonus of $75,000 has been offered the works to move outside Ontario.

The Hamilton blast furnace is now working the Robertsville and Martell iron mines, and the Zanesville mine, near Calabogie, Ont. The iron mines along the Kingston & Pembroke railway are said to be able to amply supply the demands of the Hamilton company.

The Hon. R. W. Scott is largely interested in the reopening of the iron mines on the Gatineau river, near Ottawa. It is said 200 men will be at once put to work, and are taking out for the Ohio market. Thirty years ago these mines were exclusively worked by the Hon. James Skead and others. The Gatineau mines are three in number, two on the west side of the river and one on the east side.

The directors of the Dominion Iron & Steel Co. met in Montreal, November 21st, the following directors being present: H. M. Whitney, Sir William Van Horne, R. B. Angus, James Ross, M. Dyer, Senator Mackeen and Messrs. Rogers, Pearson, and McLennan. Alfred Moxham, of the Lorraine steel works, near Cleveland, O., was appointed general manager. Mr. Moxham was formerly of Johnstown, Pa. Mr. Whitney says two of the four furnaces at Sydney will be in blast by the 1st of January next. The first of a fleet of 35 vessels, which will carry from Philadelphia to Sydney, C.B., upwards of 125,000 tons of structural steel, coke ovens, etc., began loading at that port Nov. 20th. This is material ready to be placed in position in constructing the blast furnaces, etc., at Sydney.

Mining Matters.

Rich finds of mica are reported as being opened up by J. Stewart at Cartwright, Newfoundland.

The Great Lakes Copper Co., a United States incorporation, is licensed to do business in Canada.

Seventy ovens are now turning out coke at the Acadia Coal Co.'s works, Stellarton, fifty at the back mines and twenty at the Foord pit.—Mining Record.

There is considerable activity in mica mining in the neighborhood of Ottawa. Munsen & Co., New York, are heavy buyers of mica through their Ottawa agents.

Joseph Lemieux, Charles Desmarais, F. X. Filteau and A. L. Laundry, Hull, Que., have bought a mica mine near Buckingham, Que. The claim bought is 700 acres in extent, and the price was $2,000.

At present the attendance of students at the School of Mining, Kingston, Ont., is the largest in the history of the school. After this session enlarging the school will probably be undertaken.

The Mumford improved boilers, which the Robb Engineering Co. has sent to British Columbia, have obtained such a good reputation for economy, that the Ymir Gold Mines Co., Ltd., Nelson, B.C., has ordered three of them for use at its mines.

Land in the township of Denison, south of the Creighton district, eighteen miles from Sudbury, Ont., in extent less than 200 acres, was sold last month to Dr. Ludwig Mond for $200,000. The vendors were R. J. Tough, of Toronto, and R. McConnell, and Mrs. McConnell, of Mattawa, Ont.

D'Arcy Scott, Ottawa, has bought at sheriff's sale the Walker plumbago mines at Buckingham, Que., for $70,000. The property is 1,200 acres in extent, consisting of plumbago deposits, with a factory and machinery for manufacture. In addition to the factory are quarters for employees, and a foreman's residence.

The Governors of McGill University have accepted the offer of Sir William McDonald (a cheque of $62,500), to found and endow a chair of Geology in the Faculty of Arts as a memorial to the late Sir William Dawson, emeritus principal of the University. The conditions attached to the gift were also assented to, namely, that an annuity of $2,500 should be paid to Lady Dawson during her lifetime.

R. R. Hedley, manager of the Hall mines smelter, Nelson, B.C., who spent several months examining Boundary Creek properties, says of the ores of the Boundary country: "I consider that possibilities are far greater in Boundary Creek district. There the variety is greater, and a perfectly self-fluxing ore is obtainable. Should the coal on development prove to be of good coking quality, and in sufficient quantity, a plant with a large capacity will treat ore as cheaply as anywhere on the continent. Even in bringing in coke at a cost of $12 per ton, laid down, I have no hesitation in saying that a 250-ton plant—two furnaces—using steam power, will smelt at a cost not to exceed $3.25 per ton."

An agreement has been made between the Ontario Government and a syndicate headed by Lloyd Harris, Brantford, and B. A. C. Craig, Toronto, by which the latter are to receive a concession of 2,000 acres in Dungannon, Monteagle, Carlow, Raglan and Brudenell, in Renfrew and Hastings counties, Ont. The concession embraces a series of locations in separate lots of 50 acres and over along the York branch, a tributary of the Madawaska river. In addition to paying the annual rentals as fixed by the Ontario Mines Act, the makers of the agreement are under penal bonds to spend $25,000 before September 15th,

1900; $50,000 within the next eighteen months, and $100,000 within the next three years. Of these sums it is provided that $3,000 shall be spent on experiments looking toward the production of aluminum from the rock in these locations, and a minimum of $25,000 on a plant for the manufacture of abrasive goods from corundum.

A number of practical tests are carried out each year by the staff of the Department of Mining and Metallurgy and the students of the mining course in their 4th year, in the metallurgical and ore dressing laboratories of McGill University. These consist of the milling and smelting of sample lots of ore, and are intended to apply as much as possible to the advancement of the mineral industries of Canada. At the present moment tests in concentration of low grade titaniferous and chromite iron ores, from the province of Quebec, are in progress, the success of which will have an important economic bearing. Different lots of the ore have been crushed in the various crushing machines of the laboratory, including the fine rolls, stampmill and Huntington mill. Experiments are now being conducted on these, with different sets of concentrating apparatus to determine the most suitable treatment for the ore. In connection with this work, a Browne hydrometric classifier, one of the latest additions to the ore dressing plant, is being made use of.

Personal.

A. E. Lewis, of the Atlantic Refining Co., left Toronto on the 29th ult. for Winnipeg and the Northwest in the interests of his company.

N. Hanson Greene, C.E., returned to Montreal recently from an extended trip through Central Ontario, where he has been engaged in reporting on proposed water power and harbor development works.

At the opening of the present session at McGill University the position of McDonald lecturer in Metallurgy and Assaying was left vacant by the resignation of John W. Bell, he having gone to California to take an important part in connection with a mining enterprise there. This vacancy has recently been filled by the appointment of F. W. Draper, M.Sc. Mr. Draper is a graduate of the Massachusetts Institute of Technology, having obtained his degree with high honors in the year '95. Since then he has been constantly engaged in metallurgical work, having been in the employ of a large lead and copper smelting company, for the greater part of the period, while for the last year he has held an educational appointment as Professor of Metallurgy in the University of Missouri. He gave up his position there to accept the lectureship at McGill. His attainments and experience clearly justify his selection, and it is evident that the appointment is a fortunate one for McGill, and that Dr. Porter has secured an able seconder of his efforts in the Department of Mining and Metallurgy.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports from Great Britain of interest to the metal trades for the month of October and the ten months ending October, 1898-99.

	Month of Oct.		Ten months ending October.	
	1898	1899.	1898.	1899.
Hardware	£1,412	£1,848	£18,842	£17,036
Cutlery	4,948	4,043	44,493	43,347
Pig iron	1,474	11,385	9,860	25,992
Bar, etc.	1,491	7,977	8,167	22,234
Railroad	—	38,979	9,119	152,881
Hoops, sheets, etc.	7,350	8,449	51,531	92,959
Galvanized sheets	10,938	8,520	54,650	57,589
Tin plates	19,578	46,925	121,015	188,585
Cast, wrought, etc., iron	2,537	10,500	22,387	50,250
Old (for re-manufacture)	—	883	3,574	5,073
Steel	3,644	40,663	43,032	110,340
Lead	3,172	7,691	31,090	41,788
Tin, unwrought	1,727	1,130	14,019	19,563
Alkali	10,339	7,891	42,048	33,196
Cement	5,825	7,894	23,518	30,537

SOME EXPERIENCES WITH PORTLAND CEMENT.*

BY W. K. ELDRIDGE, CITY ENGINEER, OF LAFAYETTE, IND.

The demand for Portland cements in all classes of work having been greater than the supply for several years past, has almost irresistibly tempted manufacturers to make premature shipments, adulterations and otherwise to issue defective goods, thereby placing an added burden and anxiety on the conscientious engineer in his endeavors to prevent the use of unseasoned and otherwise unsuitable cements, particularly in the construction of cement sidewalks. This he attempts by subjecting the cement before using to the usual tests now universally prescribed in all satisfactory specifications; but my experience of the past two seasons has indicated that the present method of conducting cement tests does not afford the engineer all the information he should obtain before an acceptance of the cement. Even if he takes the ill-spared time from his other duties to make a determination of the relative proportions of lime, silica and alumina, he would probably get no information of other possible ingredients of an injurious nature, and be left as helpless as before. Our tests as heretofore made are the usual ones for fineness, time of setting, constancy of volume and tensile strength; but it is easy to reason from a comparison of a number of results, including the action of the work after construction, that such tests may be and I believe are at times more or less deceptive and insufficient for perfect safety.

For instance, it is becoming customary for manufacturers to give artificial age to their cements by adding certain quantities of sulphate of lime. It has long been known that an excess of the sulphate is injurious to the cement, besides concealing certain actions that a test should be permitted to develop if it is to be reliable; but the temptation to go to excess in order to send out a product that will pass the usual tests without waiting for the proper age or requiring the extreme care necessary in its manufacture is evidently yielded to in many cases, our experience having fully shown that an honestly made cement not sufficiently aged will fail under the steam or boiling water test, thus betraying its immaturity, while a reinforced cement, though equally green, will pass all the tests that so far are customary. Any cement containing more hydrate of lime than is necessary for combination with the silica to form the tri-silicate of lime, runs the danger, in proportion to the excess, of the conversion of the free lime into the carbonate of lime, which action causes the cracking and seaming so common in cement walks. The boiling water test is intended to show this in a few hours, while it would require a long period of time otherwise. But since the presence of sulphate of lime will enable the cement to "boil" safely (and the greater the amount the surer it will "boil"), and further retards the action of the free lime in the work, sometimes to a late day, all value in this test is wholly lost when applied to "doctored" cements. Another inducement for the manufacturer to use sulphate of lime in dangerous quantities comes from the present demand for very finely ground, slow-setting cements; and as fine grinding hastens setting, a corrective must be applied, and if carried to excess, future disintegration is sure to occur, and the usual tests afford no warning. A demand for high initial strength is also called for in connection with slowness of setting, and those two qualities are also hostile; but since the immediate damaging effects of an excess of lime necessary to produce this high initial strength are concealed by the addition of sulphate of lime, we have a cement, finely ground, slow setting, of high tensile strength, but very dangerous to use. Having drawn a sample of a certain cement which failed under the boiling water test, I had the experiment made of ageing the cement artificially, using different proportions of sulphate of lime in regular proportions until the cement would not endure the test. No tests were made to determine whether the cement was over limed or simply too new; nor was any demonstration made of any sulphate that might have been in the cement before making our additions. When more time permits we expect to go into this part of the matter more deeply.

It was noticed that the cement required more water for gauging as the per cent. of sulphate was greater. Summarizing the results of the experiment, it shows that the time of setting is retarded quite uniformly with the progressive increase of sul-

*From a paper read before the American Society of Municipal Improvements at the Toronto meeting.

phate, and also that the capacity of resistance to the effects of the boiling water was strengthened in the same manner. So we find that in this particular case the addition of 3 per cent. sulphate of lime made the cement acceptable according to the prescribed standard of tests. If the cement then were accepted and used it may be subject to one of three causes for disintegration. If too new, or if over-limed, or if under-burnt, in either case the damaging effect of the free lime is only suspended, its time of action only retarded. If carbonate of lime had been added instead, the effects are the same, except that the disruptive elements in the cement may not show themselves for a year or more after being made, so slow is their development.

The detection of over-limed cements is often attempted by taking the increase in temperature during setting. This is a certain test provided the cement has not been "doctored," when the test fails, and the effect of the over-liming is retarded for weeks or perhaps months, but is almost sure to make the finished work unsound. In one case, where the temperature rose 23 degrees in five minutes the addition of only 2 per cent. of the sulphate so changed the action that the rise in temperature was only 1 degree in fifteen minutes. It seems then, certain that under present conditions of manufacture the rise in temperature and boiling water tests do not ensure a sound cement. Again, the tests for tensile strength show the progressive action of the sulphate of lime in imparting what may prove to be a meretricious strength to the cement, with a corresponding deception to the user.

In all the voluminous literature on cements, references to this branch of the subject are meager and unsatisfactory, some of them being positively erroneous. For instance, in a book on engineering construction by a well-known engineer of reputation, and much used as a text book, the statement is made that sulphate of lime quickens the setting time of cements. The theory that plaster of Paris, being a quick-setting material, imparts this property to what it is mixed with, seems plausible, but is denied by experiment. Why this is true seems so far to be unknown. The conclusion is also indicated that an unusually high tensile strength at an early period is a suspicious rather than a meritorious circumstance. In this connection, however, it should be remembered that almost all investigations in connection with cements have been and are being made by chemists in the employ of various cement manufacturing companies, and the information gained by each is carefully guarded by their employers as part of their stock in trade, not to be imparted to their rivals or customers. The benefits of the impartial and independent investigations of the properties of the constituents of asphalt pavements, as carried on by the city laboratories of Washington, Brooklyn and others, are well known and appreciated by the members of this society, and similar work and publications from the same sources on cement would be equally valuable. The competition among manufacturers to produce cements of high tensile strength has, I believe, deceived engineers into raising their requirements to correspond, until the danger line has been passed. One city has been raising the standard each year for a number of years, and parades this before the world as a virtue; but the manufacturer simply winks the other eye and produces a cement to correspond. The composition of cements and method of production are not now so different from ten years ago that a cement honestly and naturally made from the same rock and clay as then will now show double the tensile strength legitimately.

Authorities, what few there are, are much at variance about the amount of sulphate of lime permissible in Portland cements before injury is worked, one insisting on a limit of 1½ per cent., while another claims that 8 per cent. is allowable, with various other opinion in between, until the practicing engineer feels pretty much at sea in the matter. He is probably safe in adopting the minimum requirement, but with the risk of ruling out many good cements which overstep that limit, for it is possible that a safe amount in one cement might be injurious to another. But the worst feature is in the capacity of the sulphate to conceal bad qualities in cements totally disconnected with the sulphate itself. The question that confronts him is where shall he take his stand, and what can he do to protect himself and his work? What benefit is it for him to undertake a tedious and possibly expensive quantitative analysis of each sample, if a permissible limit cannot be decided upon, beyond which rejection shall be obligatory? It might be suggested that the minimum proportion of sulphate of lime allowed should not be so great as to prevent "blowing" under the boiling water test, if the cement be so constituted as to fail under this test. This rule would seem to place the limit at about 2 per cent., and it might well be less.

If it would be possible to decide this point, and then prescribe one or more tests that would be adequate, easily performed and inexpensive, certainly a great stride forward would be made toward insuring good work of reliable duration. But as the matter now stands, such tests as it is now customary to prescribe in specifications, fail to assure the engineer sufficient guaranty that his work will endure the test of time and the elements. The idea of a rough and ready test for sulphate and carbonate of lime has taken form out of some of our laboratory experiments, and may briefly be stated as follows:

After first trying the boiling test (for if the cement fails under this it is rejected by the terms of the specifications anyway), dissolve a portion of the sample in diluted hydro-chloric acid, when, if carbonate of lime be present, a strong effervescence of carbonic acid gas will take place; and as the carbonate should never be present in any good cement, sufficient grounds for rejection are found at once. The solution should be perfect, though it need not be absolutely clear; and if there be a residue on the bottom of the glass there is a strong suspicion of adulteration. If, however, nothing suspicious be found so far, the solution may be filtered and boiled, and a small quantity of barium chloride added, which will, if sulphate of lime be present, cause a precipitate which can be taken as a measure of the sulphate for comparative purposes. In order to have a standard for comparison let a competent chemist take a sample of cement known to be reliable and accurately determine the percentage of calcic sulphate, if any, and then add enough to bring it up to the allowable limit, say 2 per cent. Then the quantity of the precipitate under barium chloride may be preserved by sealing the beaker; and if all future tests are made with the same quantity by weight of cement in the same size of beaker, a visual comparison can be made with the prepared standard close enough for practical purposes.

(Continued on page xiv.)

WANTED—Draughtsman, thoroughly competent man. One accustomed to engine and saw mill work preferred. WATEROUS, Brantford.

WANTED—Young man familiar with installing and repairing electric recording meters. Give particulars of experience. Only hustlers and first-class penmen need apply. Advancement if satisfactory. Address "WATT," Canadian Engineer, Montreal.

FOR SALE

A good Water Power, 500 horse, situated one-half mile from railway, every facility for making siding to power. Address

J. D. THEUNISSON, Cookshire, Que.

FOR SALE

A complete, substantial and up-to-date
(Butt Weld)

TUBE MILL

At the present time **IN FULL OPERATION,** the property adjoining both railroad and canal systems, and near a large centre where labor can always be commanded. Price low, and terms easy.

For particulars address

J. C. Hodgson,
Room 11, Bell Telephone Building, Montreal, Canada

The Canadian Engineer

VOL. VII.—No. 9. TORONTO AND MONTREAL, JANUARY, 1900. $1.00 PER YEAR.

The Canadian Engineer.

ISSUED MONTHLY IN THE INTERESTS OF THE

CIVIL, MECHANICAL, MARINE, MINING AND SANITARY ENGINEER, THE SURVEYOR, THE MANUFACTURER, THE CONTRACTOR AND THE MERCHANT METAL TRADES.

SUBSCRIPTION—Canada and the United States, $1.00 per year; Great Britain and foreign, 6s. Advertising rates on application.

OFFICES—62 Church Street, Toronto; and Fraser Building, Montreal.

BIGGAR, SAMUEL & CO., Publishers,

E. B. BIGGAR

WATER SUPPLIES.

W. M. WATSON.

In a former article it was intimated that the water supply of Montreal was supposed to be responsible for the high death rate of that city. As therein stated I have never examined into the details of their supply and on that ground I cannot give an opinion, but I will now try to show how a supply can become the cause of an abnormal death rate, and the risk there is in towns drawing their supply of water from drainage rivers, and while doing so I shall partly draw from the works published by Dr. John C. Thresh and Dr. Parkes, both trusted and experienced medical officers of the British Government.

Rivers flowing through very thinly populated districts may yield water to which no possible objection could be taken. Many rivers, however, are utilized as sources of a public water supply which are constantly receiving sewage from towns that are situated above the intake pipe of their own town, and on that account are liable to draw into their own supply poisonous germs ejected from diseased persons or animals.

The Rivers Pollution Commissioners appointed by the Imperial Government to thoroughly investigate such matters reported in the year 1874, that after a thorough examination they had come to the conclusion, that whether they examined the organic pollution of a river at the different points of its flow, or the rate of disappearance of the organic matter contained in the sewage that gets mixed up in fresh water and incorporated with it by some violent agitation in contact with air, or, finally, the rate at which organic matter contained in sewage is dissolved and disappears in fresh water when polluted with 5 per cent. of sewage fluids, they were in each case compelled to come to the conclusion that the oxidation of organic matters in fresh water caused by introduction of sewage proceeds with great slowness, and they found it impossible to state how far sewage must flow along with the fresh water of rivers before it becomes thoroughly oxidized and harmless.

The city of Greater London draws some of its domestic water supply from the rivers Lea and Thames at a point below where the sewage of a small town is discharged into each of them, yet we are told that the inhabitants who use the water are healthy, and this fact is used to prove that water slightly contaminated with sewage is harmless, but there is a good reason why the polluted waters of the Lea and Thames are wholesome when consumed by the people of London, viz., that after it is drawn from the rivers it flows for over twenty miles in a broad, shallow, open canal which exposes the water to the purifying influences of the air and sun and by so doing it probably secures oxidation.

The characteristics of a good domestic water supply are, freedom from color, odor, taste, turbidity and the total absence of sewage germs and other injurious substances, whether animal, vegetable or mineral. Its appearance in an open reservoir will have a bluish tint. Should a body of water show a yellow-green tint, the water cannot be good, because that color indicates the presence of vegetable or animal matters in the process of decomposition. If the tint be brown it usually proves the water is collected from peaty soils, which may be unpleasant to the eye and taste, yet is generally considered harmless. If water is of a reddish tint, it indicates the presence of iron in the water, which can be eliminated by a process of thorough aeration, which will turn the color to an opalescent appearance, that will settle out of the fluid if the water is allowed to rest quietly in a reservoir for a few days, when the water will become bright and tasteless. Any water that emits an odor when boiled should be classed as unsuitable for a town's supply. Water collected from peat land is very soft and an excellent fluid to use in steam boilers and for washing purposes, but unsuitable for the manufacturing of fine paper, or to be run through lead service pipes, because the acid extracted from the vegetation that grows on peaty soil sets up a chemical action with the lead if allowed to stand idle in the pipe for a few hours, and creates a deadly poison that is delivered at the house drawing taps, and gives the consumers the lead poison which turns their gums and teeth blue and deteriorates the blood.

It is stated in the Massachusetts health report that over 1,400 samples of drinking water were examined, taken from reservoirs, lakes, rivers, brooks, etc., and only 275 of the samples were entirely free from odors. G. N. Calkins, who makes a study of water, remarks that there are three classes of odors that have come under his notice: First,

waters that contain chemical or putrefactive decomposition; second, waters that contain odors of growth; third, water containing physical disintegration, the last two being due to odorous oils.

Thresh states that the fishy smell often found in drinking water is due to a microbe called Uroglena Americana, Professor Remson says it is due to a decomposition of a fresh water sponge, while Mr. Rafter says that it is caused by a germ named Valvax Globator.

The storage reservoir of Norwood at Plymouth, Mass., was well charged with the germ Uroglena Americana in 1892, but as long as the water remained in the reservoir and the germs were in active life, the waters did not smell, but when they were drawn into the water-mains life became extinct and they became completely disintegrated and liberated a strong smelling, oily element that was very unpleasant and unhealthy.

In a village in Essex, Eng., the water supply was poisoned by dead fish that had died in the water during the time the reservoir was frozen over, and afterward set up putrefaction; another village in the same county had the water in the watermains poisoned by a large number of small eels that were drawn into the supply pipes where they lost their life and set up decomposition. (See British Local Government report for 1887.) I lately visited the source of supply of a town that draws from the waters of the Oswegatchie River and noticed that gas rose through the volume of water from which they took their supply in many places, just as if peas were shot upward through the water causing bubbles at the surface and miniature colored circles for a second on the water where the gas burst forth. The water of this river is of a reddish color which shows the presence of iron in the water, and the gas discharged proved that there were vegetable or animal substances in a state of decomposition in the water. This class of water I should consider unfit for a public supply unless well filtered.

Rivers are natural open sewers, where the filth discharged by the inhabitants living along the land contained within the water shed is carried away to the salt water of the sea for purification; during the passage of the water towards the sea most of the solid disagreeable matters the water contains settle to the bed of the streams, occasionally making their appearance when the waters of the river are violently disturbed and the filth raked up from the bottom by wind storms. At such times the water is unsafe to use for domestic purposes and the supply should be discontinued until the river becomes calm and settled again.

A couple of weeks since I was on a diver's raft attending the laying of a water pipe into a river; the diver was down about twenty feet when a due east wind storm occurred, churning up the river water as if a number of gigantic Ferris wheel bucket pumps had been set in motion. The water quickly turned from a bright, clear fluid to a bluish black, and the diver was soon unable to see but a few inches before his glass; when the turbulent water was placed in a tumbler it exposed a great number of particles of dirt and had a slight odor. Such sudden changes in a quality of river water are common where the sewage from the inhabitants and the refuse of manufacturers are discharged into it. The waters of rivers may easily purify the dirty fluids collected from the face of the land and stagnant pools, but they cannot also provide for the purification of the sewage of the inhabitants and the foul refuse cast out by lumber mills, dyehouses, soap works, sugar refineries, chemical works and other factories. When such substances enter the river they go down the stream, the particles clinging together, seldom mixing with the fresh water of the river until the heavy solids have settled down to the bed of the river, or by some means the fresh and sewage waters are violently agitated to compel incorporation. The solids carry with them anerobic germs which breed and multiply until disturbed by storms and they receive partial oxidation by the agitation it gets during the commotion. Should such water enter the town's waterpipe the dirt would settle to the invert of the water main, especially if such water mains are larger than are necessary to supply the water takers. When once the foul solids secure lodgment in the water mains they will ferment and breed more germs, and continue to breed and increase the contamination of the water supply until the germs and dirt are well washed out; this is why efficient provision should always be made to thoroughly clean out the water pipes.

(To be continued.)

ST. LAWRENCE LEVELS.

The Chicago Drainage Canal was opened January 2nd. The water should have been let in December 1st, but legal delays made themselves felt. It was to be hoped that these delays would continue. Not that we wished to have the people of Chicago supping sewage as has been their wont these many years, nor drawing all their liquid supplies from Milwaukee, as we fear there is danger, but if the St. Lawrence is to be maintained at anything like its present level and our costly canals to be available, the people of Chicago must still continue to receive their present filthy water supply of which their own analysts constantly report "unusable." The engineers appointed by the United States Government to enquire into the probable effects of the opening of the canal state that the lake levels will be reduced by at least six inches and perhaps three feet. We have not alarmed ourselves here in Canada hitherto about this matter because we knew that what we suffered in loss of harbors and ship channels would be small in comparison with the loss of such towns as Buffalo, where each inch of deficiency in the harbor costs one million dollars for dredging, but a new danger threatens us, and we must now take measures to protect our interests, and that at once, before our all too friendly Government at Ottawa has fallen into the trap which has been set for the Canadian interest. It is contained in the report of the engineers, designated to make surveys and examinations of deep waterways and routes between the great lakes and Atlantic tide waters, which recommends the regulation of the Lake Erie level by controlling the discharge through the Niagara River by a system of fixed weirs, built near the head of the Niagara River, and a series of sluices to be operated in connection with them so as to control the discharge of the lake, and reduce the variation of its level to a small amount.

This will, of course, entail the erection of wing dams on the St. Lawrence to make Lake Ontario ports and the St. Lawrence channels navigable. It is a scheme to throw all the loss of level due to the new canal onto Lake Ontario and the St. Lawrence. The dams will make whatever level is determined upon permanent, but whatever loss is due to the diminished flow will fall on the St. Lawrence. But more serious than that, in both its first cost and its disastrous delays, would be the absolutely necessary dam and locks below Montreal at the foot of Lake St. Peter.

The Chicago drainage canal may not ruin the Canadian lake and river towns and cities, and if it does it also

destroys many great cities of the United States. But the Chicago drainage and the Niagara dam together mean the absolute ruin of Montreal as an ocean port. It will be no more an ocean port than Lachine or Valleyfield, and Buffalo will maintain its position as the chief centre of the grain carrying trade.

MATHEMATICS IN THE MECHANICAL TRADES.*

BY J. S. PLASKETT, B.A.

The subject of this paper may be considered from two standpoints. The first, and to undergraduates the most familiar point of view, is from the standpoint of the student entering or intending to enter any of the mechanical trades. A graduate of a School of Science, about to put his knowledge to the test of practical application, being a good example of this class. The second is from the standpoint of the mechanic, who, ambitious to improve his standing, determines to apply himself to those studies most likely to be of benefit to him. At the outset, however, let me disclaim any intention of touching upon the subject of technical education. I will confine myself principally to discussing the subject from the second standpoint, giving examples of the application of mathematics to the mechanical trades. Examples will also be given in which mathematical methods are justifiably superseded by mechanical ones.

The question that naturally arises in the first place is what constitutes a mechanic, or what are the mechanical trades. According to the generally accepted definition, a mechanic is "one who works with machines or implements; one skilled in shaping or uniting materials, as wood, metal, etc., into any kind of structure, or machine, or other object requiring the use of tools or instruments." The mechanical trades then would embrace those occupations at which mechanics are engaged. The ordinary use of the term seems, however, to confine the mechanical trades to those in which metal is worked, and these are what will be considered almost entirely in this paper.

The mathematical knowledge of the average apprentice or journeyman in these trades is comprised in a short and inadequate Public School training in arithmetic. They have not even touched any other branches of mathematics, while their knowledge of aritlimetic is very limited and quite insufficient to meet many of the demands that will be made upon it. Many of the operations which mechanics have to perform are done without being fully comprehended, while many others cannot be done unaided, simply from failing to understand, what would seem to even the tyro in mathematics a very simple problem.

In consequence the mechanical trades are burdened with innumerable rules and formulae, bearing on the difficulties most likely to arise, and in the hope of overcoming the lack of mathematical knowledge on the part of the operators. A very familiar instance, at least to machinists, of such rules is that relating to the cutting of screws on engine lathes. Screw cutting on a lathe depends, as no doubt most of you know, on the motion of the tool carriage at a rate definitely proportional to the revolutions of the spindle and work to be screwed.

*A paper read before the Mathematical and Physical Society of the University of Toronto, Dec. 1st, 1899.

As the carriage is moved by the revolution of a screw, called the lead screw, of a pitch which is usually 4, 6, or 8 threads to the inch, the problem resolves itself, in simple gearing, into finding two gear wheels among the set which accompanies the lathe, the numbers of whose teeth are in the ratio of the pitch required to the pitch of the lead screw. Thus, if a screw of 14 threads to the inch is required, and the lead screw is 6 threads to the inch, the gears must be in the ratio of 14 to 6. The gear on the spindle generally remains constant, say it has 36 teeth. Then on the lead screw will be required a gear of 14-6 x 36, or 84 teeth. The intermediate gear that connects the spindle and screw gears has no effect on the rate of motion, but simply serves to communicate the motion. This does not form a very intricate piece of calculation, and yet nine times out of ten you will see the machinist consulting his screw cutting tables, which, by the way, are always attached to the lathe, whenever a thread is to be cut.

If the gearing is compounded, that is if an extra pair of gears fastened to the same axle is introduced between the spindle and the screw gear, instead of the intermediate gear, the calculations are not quite so simple, although performed on the same principle, and

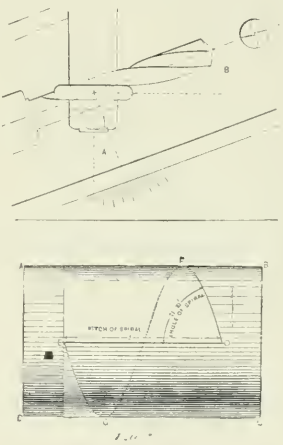

FIG. 1.

are more intricate still when spirals are required to be cut on the milling machine, a familiar example of such a spiral being the groove in a twist drill. This groove is produced by a rotating cutter somewhat similar in principle to a small circular saw, only having teeth properly shaped to produce the groove. It is evident from the upper half of Fig. 1, that the work must rotate and move longitudinally at the same time, and that these movements must bear some definite ratio to one another. When we consider the fact that the longitudinal motion is given by the rotation of a screw, that the rotary motion of the work is produced by the rotation of a worm gearing into a worm wheel to whose axis the work is fastened, and that these two rotary motions are combined (Fig. 2), by connecting the worm shaft and the screw by gears, some idea of the trickiness, I can hardly call it difficulty, of the problem dawns upon us. In addition to this, the work and the cutter must be set at an angle to one another (Fig. 1), this angle depending on the diameter of the work and the pitch of the spiral; a spiral, technically speaking, being nothing

more than a screw of great pitch, from ten to one hundred times as great as an ordinary screw of the same diameter. The first part of the calculation requires arithmetic only, but the second a slight knowledge of trigonometry. As can readily be seen from the lower half of Fig. 1, the angle that the spiral makes with the axis of the work, and consequently the angle between the cutter and the work, is the angle whose natural tangent is the ratio of the circumference of the work to the pitch of the spiral. Of course tables are given to cover most of the cases that will arise, but the utility of being able to calculate the proper gears and angle appears when a spiral is to be cut which is not on the tables. Instances like the above of the necessity of arithmetical calculations in the mechanical trades may be multiplied indefinitely, while the inability of the average mechanic to undertake them is clearly shown by

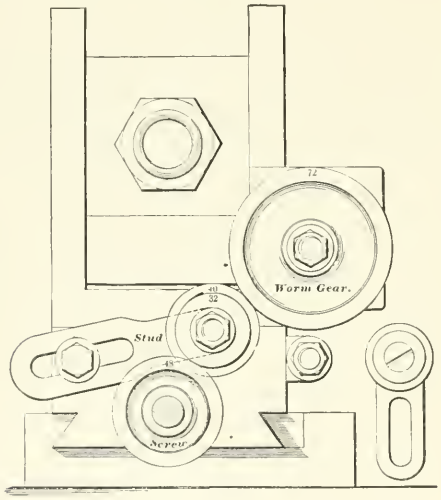

Fig. 2.

the rules, formulae and tables, which are met so frequently. I venture to say, however, that the one branch of mathematics most universally useful in all the mechanical trades is that of geometry. By geometry is not only meant the ordinary Collegiate Institute idea of the term, including practically only Euclid's elements, but also the more modern constructive and descriptive part of the subject, which is usually included in the study of mechanical drawing. Euclid, although useful, and, I think, necessary as a training for mechanics, and also as an aid in many problems likely to arise, is not so generally used practically as descriptive geometry. A knowledge of descriptive geometry and mechanical drawing will prove of very great service in every one of the mechanic arts, and is, in fact, indispensable in most of them. That mechanics should be able to read drawings is absolutely necessary. To be able to reproduce them would indicate the acquisition of a very fair knowledge of geometry, in no other way so easily attained.

To illustrate the importance of geometry in the mechanical trades seems hardly necessary, when you consider that every structure and machine is based on geometrical lines and conforms to geometrical principles. A few examples showing the application of geometry in some mechanical problems will, however, be given. How would the carpenter, if geometry were unknown, determine the forms and sizes of the various parts used in building construction? Or how would the tinsmith construct any vessels for domestic use?

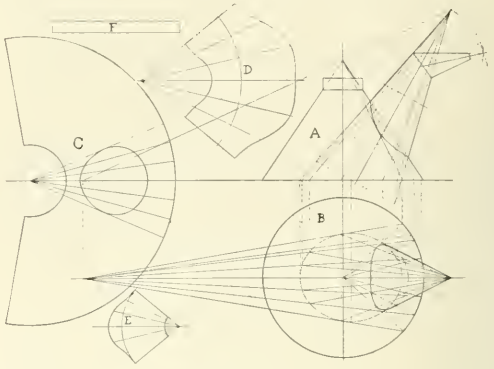

Fig. 3.

Even so simple a utensil as an ordinary tin pail would require some thought, perhaps, from our undergraduates in mathematics, in order to develop the proper form to cut the tin, that when rolled up and joined, it might be the correct shape. Again, let us consider another domestic utensil, a tin teapot. Although the tin is not beneficial to the flavor of the tea made in it, the construction of the pot itself forms a very fine problem. Figure 3, A, shows the general outline of the teapot, which I will grant is not an orthodox shape, but the peculiarities have been exaggerated for the sake of example. B. is the view from above showing the intersection of the body and spout. C. is the developed form of the body of the teapot; D. the form of the lower, E. of the upper part of the spout; F. is the band at the top, while the bottom, of course, will be a circle of the same diameter as B. The development of these forms would I fancy be rather too intricate for most of us. But you may say that tinsmiths cut the tin approximately to shape and then trim it afterwards, or that they have patterns. Well, how close an approximation would your

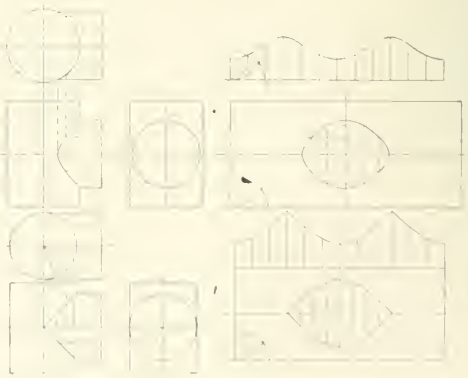

Fig. 4.

first guess of the shape of the spout be? Or how were the patterns obtained? How do boilermakers, in the construction of boilers, determine the forms to be given to the sheets, that, when rolled up, they may ex-

actly fit where two surfaces intersect, as at the junction of the dome to the main shell? The sheets are not very easily trimmed in this case. Figure 4 will illustrate the forms, the upper being the ordinary boiler and dome, and the lower the intersection of two circular cylinders of equal diameters at right angles.

In the construction of machines, work has often to be laid out, holes drilled, and other operations performed on pieces which have to come together exactly and fit perfectly, and which cannot be tried and made to suit. Geometrical methods are adapted to this purpose, and it is marvellous how accurately such work can be done. A similar example, and one perhaps more familiar to you, is in stonecutting. The stones are cut to shape and put in place, and I never remember seeing one taken down and altered. Many examples of difficult geometrical construction in stonework may be seen around the doorways and arches in University College.

From these examples it will be seen how universally geometry is employed in the mechanical trades, and how necessary a knowledge of its elementary principles at least is to all artisans. Let it not be understood, however, that it is always preferable in the practice of the mechanic arts to employ theoretical geometrical methods. Very often such is not the case, and mechanical aids are to be preferred. Who would think, for instance, of drawing a line perpendicular to another line, or of finding out if two plane surfaces were at right angles by Euclid's method, when an accurate steel square was obtainable? What would be thought of a

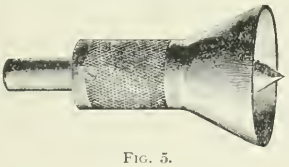

Fig. 5.
Bell Centering Punch.

machinist, who, when told to centre a circular shaft, tried to do so by bisecting the perpendicular through the middle point of any chord? As an example of mechanical methods, I will describe three ways in which this would usually be done. The bell centering punch (Fig 5), consists of a hollow cone with the punch constrained to move along the axis. This answers very well if the shafting is small and no great accuracy is required. A second method is to make a mark by a centre punch, as near the centre as possible, and then rotate the shaft between the lathe centres. It will be immediately seen when it is accurately centred by the periphery of the shaft revolving truly. If it does not run truly, the mark is punched over to the required side and again tested. As soon as the shaft runs truly, a small hole is drilled at the centre thus obtained, and this hole is countersunk by a centre reamer ground to the proper angle to fit the centres. A third and perhaps commoner method is to place the shaft in the lathe, the ordinary conical tail centre being replaced by what is called a square centre. This has the form of a square pyramid, the angle between the opposite edges being usually 60°. If the shaft is made to rotate against this square centre, while its periphery rubs against a bar firmly fixed in the tool post, it is evident that, as the sharp edges of the centre cut into the end of the shaft, they will form a conical hole. This hole will be exactly in the centre, for the outside of the shaft is constrained to move truly. The two latter methods depend of course on the geometrical property of the invariability in length of radii of the same circle.

Another problem continually arising is the division of circles, or rather the circumferences of circles, into any given number of equal parts. Euclid's method, by inscribing regular figures, is never used in practice. It

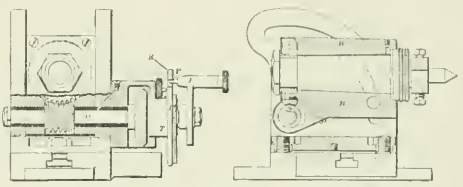

Fig. 6.

is too tedious, is only adapted for a few divisions, and is wanting in accuracy. When the division is made by hand, the circumference is always stepped off by trial with a pair of steel dividers with fine points. When the arc included by the dividers becomes so near the required one that the points cannot be moved a small enough distance by the adjusting screw, the final adjustment is made by rubbing down the proper sides of the points on an oil stone. It is by this method that large cast gears, used in mill work, three or four feet in diameter, and six inch face, have the teeth spaced off regularly, drawn to the proper form, and then chipped and filed to suit.

As in the method of centering, dividing by machine is decidedly more convenient, accurate, and expeditious. Wherever there is a milling machine, all dividing or indexing, as it is sometimes called, is performed by the index head of the machine. The head of which you see two views in the figure (Fig. 6), consists of a worm wheel, which is firmly attached to the work spindle, while gearing into this worm wheel is a worm attached to the spindle O. The worm wheel has usually 40 teeth, so that one revolution of the worm spindle, which has the crank J attached, gives 1-40th of a revolution of the work spindle, or will divide a circle attached to the work spindle into 40 parts. Suppose it is wished to divide a circle into, say, 76 parts. Then the worm

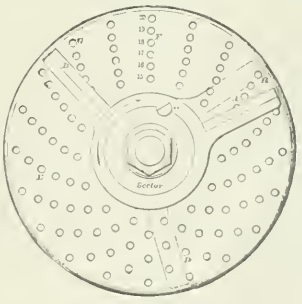

Fig 7.

must turn 40-76th's or 10-19th's of a revolution. Fastened to the side of the head (I, fig 6), concentric with the worm spindle is an index plate (fig. 7), consisting of circles of concentric equally spaced holes into

which the pin on the crank enters. To get 1-76th of a division, the pin must evidently move over 10 spaces in the 19-hole circle. By continuing to move over 10 spaces you finally divide the circle. The sectors shown are adjustable, and form a guide to the space moved over, obviating the necessity of counting at every division. Although the calculations required are not very intricate, the tables supplied are, I may safely say, always used.

This method, when the worm and wheel are accurately cut, furnishes excellent results, far excelling in speed and accuracy the ordinary stepping-off process. But if it is wished to graduate circles for astronomical purposes, as near accuracy as possible is required. The divisions are made by a worm wheel and worm, as before, but in this case, in the most approved form, the worm wheel is nearly 4 ft. in diameter, and has 4,320 teeth around the circumference, each tooth, therefore, representing a division of five minutes of arc. This wheel is in the first place divided by hand and requires the most extreme care, delicacy of touch, and microscopical exactness.

One method of dividing it, due to John Troughton, is a method of bisection. The wheel is very carefully turned and polished (no scratches) on its edge and face, and along a fine circle drawn on the face near the periphery the divisions are laid out. The radius laid out from zero gives 60°. This arc bisected and the half laid off from 60° gives 90°. The arc between 60° and

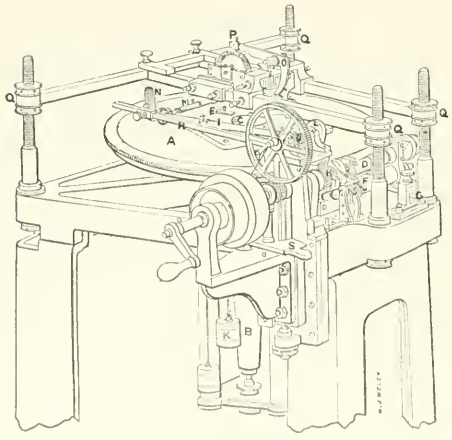

Fig. 8

Dividing Engine

90° bisected, gives 75°, and between 75° and 90° gives 82° 30′, while the arc between 82° 30′ and 90° bisected, gives 86° 15′. Further, the arc between 82° 30′ and 86° 15′, trisected, gives 85°, while the arc between 85° and 86° 15′, trisected, gives 85° 25′. Lastly, the arc between 85° and 85° 25′, quinquisected, gives 85° 20′, and this equals 5′ x 2, and so can be finally divided by continual bisection. A very fine dot, visible only to the microscope, is made at each point of division, and the errors of these dots are determined and tabulated by the aid of reading microscopes, mounted on radial arms. Finally, the teeth are cut exactly opposite the corrected positions of the dots by a cutter. Fig. 8 shows the completed machine. The plate A, is 16 inches in diameter, and has two sets of divisions, one faint on a silver inlaid ring, and the other stronger on the gun-metal. The rest of the machinery is for making the scratch and turning the plate automatically.

Another and very appropriate example of the use of mathematics arises from the cutting of the teeth on such worm wheels. Given a wheel of given diameter, with a given number of teeth, find the pitch of the worm, and the converse, given the pitch of the worm, find the diameter of the wheel for any given number of teeth. Again, given the pitch and the diameter of the worm, find the angle at which the cutter must be set in order that the teeth and worm may exactly fit. Finally, given the shape of the worm thread, determine the form of the cutter, that the wheel and worm may work smoothly and uniformly together. To solve these problems will require, besides arithmetic, a fairly thorough knowledge of geometry and elementary trigonometry, and also a knowledge of the properties of, and an ability to trace two plane curves, the involute and the epicycloid.

Such problems are continually arising in machine work, and although rules and tables can be obtained for the guidance of workmen in standard cases, other cases are very likely to arise in which original calculations will have to be made. When such is the case, how much better it is that the workman should be able to undertake the calculations himself. He then has the satisfaction that always follows a problem solved, and moreover stands a much better chance of advancement than if he were a mere machine, able only to follow rules, and depending on the guidance of tables.

It follows, from the examples that have been given, that the mathematics required in the actual performance of ordinary operations, if the calculation is to be done by the mechanic, are a thorough knowledge of, and capability of applying the principles of arithmetic, a knowledge of geometry, including descriptive geometry and mechanical drawing, and a knowledge of the elements of plane trigonometry, particularly the solution of triangles. These seem to me to be necessary to the comprehension and intelligent performance of many common operations.

I can only, in conclusion, state my belief that, although mechanics manage to perform their work tolerably satisfactorily with their present very deficient mathematical training, if even such a course of mathematics as I have outlined could be imparted to every artisan, both the quality and quantity of the work produced would be considerably enhanced, and also there would result to the workman himself a very decided advantage.

—The Engineers' Club of Toronto, at its meeting Dec. 5th, heard a very interesting paper on the Trigonometrical Survey of the Dominion, by O. J. Klotz, Astronomer to the Department of the Interior, Ottawa. The club then discussed the sewage disposal report of C. H. Rust, city engineer, Toronto, and at the close of the discussion Prof. J. Galbraith moved and E. B. Temple seconded a resolution which calls for the disposal of Toronto's sewage otherwise than in the harbor, by building intercepting sewers and by "treating the sewage by the most approved modern methods." This seems easy enough in a resolution and the Engineers' Club doubtless felt that the sanitary condition of the city was being vastly improved, but it

might be more practicable if the "most approved modern methods" were known and agreed upon. Does the Engineers' Club feel able to pronounce on this point, or does it wish to leave the matter to the experts in the Toronto city council. Perhaps it is better to wait till the Royal Commission appointed by the British Government to determine this very point has reported. A lasting benefit would be conferred on the profession, not to mention the public, if the Engineers' Club would set this matter at rest.

—Victoria, B.C., is a storm centre from an engineering point of view. We have given some notes, from time to time, on the ups and downs of its professional advisers. There is now on hand an extra fine row over the sewage system, which is planned on the separate system, and into which it has been proposed to turn the storm water.

THE CANALS OF CANADA.*

The canals of Canada is a subject that has interested the Canadian people for more than a century. The greatest of our engineers, both civil and military, have labored in their development. our politicians have found in them the cause for bitterest controversy, and our merchants have looked forward time and again to supremacy in the export trade to Great Britain and Europe after their completion; and yet to-day, the existence of many of them is unknown to most of us, and the aid they have given to the growth of our commerce but little appreciated. Their story may best be told by considering, first their history, then their construction where viewed as examples of the engineer's art, and lastly, their commercial importance. The history of the westward movement of our civilization during the present century, is, in the main, the record of the triumphs of our engineers in developing means of transportation; and the periods of greatest activity in our political life have been followed by large expenditures upon roads, railroads and canals. To-day, confident as we are that owing to the justice of our governmental system, and the fertility of our soil, our unoccupied lands present to the emigrant farmer attractions unequalled by those of any other government-held land in the world; we are still subsidizing freely every improvement in transportation facilities for the unoccupied districts, in the firm belief that our lands will not be taken up, until they are made readily accessible. It is to this long recognized principle that our canals owe their commencement.

Montreal from the days of Maisonneuve to the days of Alexander McKenzie and his associates, had but one trade—the fur-trade, and that commerce taxed to the full the transportation facilities of the country. Lachine was the western port of the city, and from it set out the trading expeditions, with their goods laden in either batteaux or canoes, that is in lumbermen's boats or in birch-bark canoes, as we know them on our rivers to-day. At the close of the 18th century they were about 30 feet long, with 6 feet beam, and could carry from three to five tons of cargo; the canoes being used on the Ottawa and Georgian Bay route, as their light weight of about 500 pounds made it possible to carry them across the numerous portages; and the batteaux were best suited to the rocky and dangerous rapids of the St. Lawrence. The profits of the trade must have been very great, for the length of time that was required to complete a transaction was appalling. Alexander Mackenzie, in his book of travels, states that it took over four years to get goods from London to trade them for furs in the Northwest, and to sell those furs in London.

It was to aid this trade that Dallier de Casson, the soldier, explorer and priest, then Superior of the Seminary of St. Sulpice, entered into contract with the engineer, Catalogne, for the construction of a cut across the divide between Lachine and little Lake St. Pierre, from which there was a canoe route to Montreal. This was in the year 1700, and although, owing to Dallier de Casson's death, the work was not completed, the gentlemen of the Seminary never ceased petitioning the King for its construction, until the old regime had passed away. The fur trade, rudely interrupted by the final struggle between France and England, was resuming its activities when the American War of Independence broke out, and after the shock of the Continental armies had broken in vain on the rock of Quebec, the soldier Governor Haldimand saw, that in order to maintain the fortified posts of the Crown in the west, built indeed largely for the benefit of the fur trade, he must have better means of forwarding supplies to them, and for that purpose he gave orders in 1779 for the building of the first St. Lawrence canal. This was built at the Cascades rapids under Capt. Twiss as engineer, and was completed in 1781; the lock being able to pass boats six feet wide, and drawing a foot and a half of water. By 1783 improvements were completed on this scale around all the rapids between Lake St. Louis and Lake St. Francis, and nothing further was done by the Government until after 1800.

But, while the Montreal traders were cheerfully paying toll to the War Department for the use of these locks, two great events of Canadian history had occurred, both in the year 1783. At that date the Northwestern Fur-Trading Company, of Montreal, began the brief, glorious and stormy life that was for awhile the life of Montreal. Its founders were men unsurpassed in our annals for vigor, courage, enterprise and ambition; their memories still linger in our streets, and are writ large upon the map of Canada; for they were the men who pushed our commercial confines to the Arctic and to the Pacific, and who, proving more than a match for John Jacob Astor and his New York associates, saved for us the Northwest. But their passions were as strong as their vigor and enterprise, and fiercely and jealously the great houses composing the company struggled against one another, and fiercely and jealously they made war upon the Hudson's Bay Company and the early Selkirk colonies, until worn out by the long struggle, the companies were at length amalgamated in 1821, and the fur trade passed away from Montreal. But in the legal records of their internal struggles Mr. Douglas Brymner found the particulars of a totally forgotten work; and a few years ago, guided by the information which he published in the Canadian Archives, engineers uncovered at Sault Ste. Marie the foundations of the first lock built by that rapid, a wooden structure, 30 feet long and 8½ feet wide, opened in 1798 by one section of the Northwest Company for the passage of their trade, and probably destroyed during the American war of 1812.

In 1783, also was signed the treaty of Versailles, perhaps the most disgraceful and cowardly action ever committed by Great Britain, when by it she abandoned the Loyalists, who had so staunchly stood for the United Empire, to persecution, confiscation and death at the hands of their enemies; but by that iniquity Canada was the gainer, and from 1784 to 1790 the Loyalists poured into her confines to build up the provinces of Ontario and New Brunswick. They had been among the ablest and most public-spirited of the citizens of the commonwealths from which they came, and from the time that they were fairly settled in Upper Canada, the cry for better access to the sea never ceased. A hundred years ago that cry could mean nothing but water-ways; a fact that is brought home to us with startling effect, when we read the speech of Adam Lymburner, a Canadian delegate sent to England to oppose the passage of the Constitution Act of 1791. That Act separated Upper and Lower Canada, and Lymburner contended that this separation was completely unnecessary as Canada never could extend beyond Hamilton, the Niagara Falls forming an insuperable obstacle.

To accommodate the rapid developing commerce of Upper Canada some improvements were made in the St. Lawrence route between 1800 and 1810, but only on the outbreak of the American War of 1812 was the insufficiency of the canals on the route fully realized by both people and Government. The building of the first Lachine canal was advised by Prevost, the Governor-General in 1815, but it was not until 1821 that the Government of Lower Canada, subsidized by the Imperial Government, undertook this work. It was completed in 1825 with stone locks 100 feet long, 20 feet wide, and 5 feet deep. While it was in progress the fur trade was passing away, and the great Quebec lumber trade was rapidly growing under the liberal fiscal policy of Great Britain towards her American colonies; its booms, dams and chutes were seen on every river; it

*From a paper by Arthur Weir, B.Sc., before the Applied Science students of McGill University.

crowded the ports of Quebec with numberless sailing vessels and built up the great fortunes of that city. The rafts of this trade passed Montreal by, but the grain trade for which our merchants and forwarders still struggle was greatly aided by the same liberal fiscal policy that extended to our grain exports that protection in the home markets that our producers now so earnestly covet.

While Lower Canada was building the Lachine canal, the Imperial Government was considering the safest means of securing water communication with Upper Canada. The works being built for purposes of defence the St. Lawrence route could not be utilized, and that by the Ottawa and Rideau rivers to Kingston was chosen. Upper Canada refused to contribute to this work on the ground that it would not furnish as suitable a commercial route as the St. Lawrence, and this refusal seems to have had the approval of the Royal Engineers, who for military reasons held that the War Department should have entire control of the canal. This view was long held and it was not until 1856 that the Home Government handed over the Rideau canal to Canada.

It was commenced by Col. By in 1826, and opened in 1832, the Carillon and Grenville canals on the Ottawa, which formed part of the route, being opened in 1834. The engineers of to-day sometimes make mistakes in their estimates, but it is questionable if their errors ever equal those made on the Rideau canal, which was commenced on an estimate of £169,000 and cost £800,000 to complete. It is but justice, however, to say that owing to the efforts of Col. By the magnitude of the work was greatly increased during construction, in order to make it suitable for steamboat traffic, which had been commenced upon the St. Lawrence by the Hon. John Molson in 1809. The Rideau route immediately became the route for heavy traffic to the west, and the attractions and the cuisine of its steamers were as energetically advertised as are those of the Empress steamers to-day. The locks were 134 x 32 x 5½, but the through route was throttled by three locks of the Grenville canal, which were built before the adoption of Col. By's report, with dimensions of 107 x 20 x 5½ and by a private lock at Vaudreuil. The Grenville locks were not rebuilt until after Confederation.

The Cascades and Cedar Rapids being within the limits of Lower Canada, the St. Lawrence route could not be opened except with the consent of that province, and it was openly charged in Upper Canada that the selfish interests of Montreal prevented this improvement. Angry at this indifference or opposition, out of sympathy with the military ends of Home Government, and urged on by that section of the province which lay below the mouth of the Rideau canal, Upper Canada was pushing on her own canal schemes. Chiefest of these was the Welland canal, built to connect Lake Erie with Lake Ontario, and to overcome Adam Lymburner's insuperable obstacle. Many claims have been made for the honor of the inception of this great enterprise, but that honor seems hardly worth striving for, for the historian Kingsford, himself an engineer, says of it, that "a wilder, more ill considered scheme than the one originally put forth, one showing more ignorance and recklessness on the part of the projectors, it is scarcely possible to conceive." Commenced in 1825 by a chartered company it was sufficiently completed by November, 1828, to let two vessels through its wooden locks of 100 x 22 x 7. But misfortune came fast, and no other chartered company perhaps has ever left such a record of intrigue, mismanagement, and disaster. Subscriptions were solicited everywhere, in Lower Canada, in New Brunswick, in New York and in England; subsidies were given by Upper Canada, by Lower Canada, and by England, and the company struggled on until the story was ended by the purchase of its works by Upper Canada in 1830. Those were troublous days in that province, and the struggle against the Family Compact was being carried on in all its intemperance and virulence, but of all the Parliamentary reports of the period none is more extraordinary than that dealing with the Welland Canal Company. It characterizes many of the proceedings of the directorate as "inexplicable; no statement has been heard which supports the justice or even expediency of arrangements which, if applied to the ordinary transactions of life, would be deemed not only ruinous but the result of insanity." And it ends, even as a Parliamentary enquiry of to day, by exonerating everybody concerned.

Upper Canada had commenced the Trent canal, and all but completed the Cornwall canal, when the great political struggle suddenly ended, and the adoption of Lord Durham's report brought about the union of the provinces in 1841. In 1840 Col. Philpotts, R.E., presented a report upon the canal navigation of the Canadas, which had been originally called for by Lord Durham. In it he recommends the St. Lawrence route as the only Canadian route that could be made to compete successfully with the Erie canal. Going into detail, he points out that the Welland canal with its badly built line and rotting locks must be reconstructed, that the Cornwall canal is unfinished and its structures rapidly deteriorating, that a new canal must be built past the Cascades and Cedars, and that the Lachine must be greatly enlarged.

Immediately after the union commenced an era of great activity in canal construction under the management of a Board of Works with H. H. Killaly as chairman, and S. Keefer as chief engineer. In these enterprises the Canadas were assured of the fullest support of the Imperial Government, both financial and military, if such were required. The recommendations of Col. Philpotts were closely followed, and by 1848, a nine foot route was open from Lake Erie to the sea. In the walls of its first completed work, the Cornwall canal remained for many years a record of changing conditions, for its locks alone of all the St. Lawrence canals were built 55 feet wide, the remainder being made 45 feet because the propeller screw had been invented and had proved more suitable for navigation than the paddle wheel. The locks of the St. Lawrence canals were built 200 x 45 x 9, and they were rapidly opened, the Cornwall in 1843, the Beauharnois in 1845 and the Lachine in 1848, and with their completion the traffic left the Rideau route forever, and it remains to-day a work of local utility, and a monument to the efforts that Great Britain put forth for the defence of Canada. In these enlargements there are two points worthy of note. The locks of the new Welland were built only 180 x 26½ feet, because the Governor-General did not think the country could bear the greater cost of the full sized locks, and the location of the Beauharnois canals gave rise to one of the bitterest political controversies of the day. It was charged that the Governor-General influenced by the Seignior of Beauharnois had caused the Board of Works to choose the present location, and that the canal ought to have been built upon the north shore of the river. The Board of Works seems, however, to have been supported by the best engineers of the day, and the controversy is only worthy of note now, because the last of the new 14 foot canals is being built upon the north shore location that was then so hotly advocated. While these works were progressing on the main route, the Chambly canal commenced by Lower Canada in the previous decade was completed, and the private lock at Vaudreuil rendered unnecessary by the opening of a Government lock at St. Annes.

The canal history of the next twenty years is one of minor developments and repairs, to accommodate a steadily increasing traffic; but with it grew a feeling that owing to the rapid increase in the size of the lake vessels, and the great activity displayed by the American railroads in concentrating the eastward traffic on the line from Buffalo to New York, that the canals must be greatly enlarged to enable our shippers to secure a share of that traffic. As more than once before, there was no practical outcome for this feeling until another great political change had come, and the Dominion was ushered in to carry on the policy instituted by Upper Canada and adopted by the United Canadas. In 1870 a commission with Hugh Allan as chairman, and S. Keefer as secretary, was appointed to consider canal enlargement. Their report of 1871 fully reviews the whole subject, and will be referred to later. They recommended enlarging the St Lawrence canal to 12 feet draught, with locks of 270 x 45, and this work was promptly undertaken by the Government, although the draught was subsequently increased to 14 feet It is not yet completed, but we may hope to see vessels drawing 14 feet of water coming down to Montreal in the latter part of 1899 or the beginning of 1900. The commission also recommended some improvements on the Ottawa river canals, which have been completed.

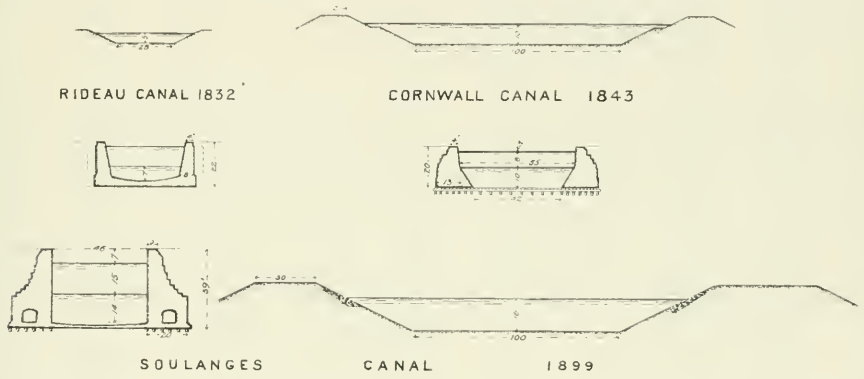
Thus at the close of the century Canada finds herself possessed of a system of inland navigation, which for extent and capacity is unequalled anywhere in the world, and of whose

construction and maintenance out of her slender resources she is justly proud. First, the St. Lawrence, extending for a total length of 71 miles, ascending a total height of 551 feet, and opening up a continuous 14 feet navigation from Montreal to Port Arthur, a distance of 1,274 miles. The locks, with one exception, are built to pass vessels 255 feet long and 44½ feet wide. The one exception is the Sault Ste. Marie lock, which is designed for the lake trade, and is 900 feet long, 60 feet wide and 20 feet deep. The separate canals in this system are, the Lachine, the Soulanges, the Cornwall, the Williamsburg, the Welland and the Sault Ste. Marie, containing in all 47 locks. Second, the Ottawa and Rideau system, from Lachine to Kingston by this route is 237 miles. The reach of it, that extends from Montreal to Ottawa, has been improved since Confederation, and by the St. Anne's, Carillon and Grenville canals passage is afforded for vessels less than 185 feet long by 44½ feet wide with 9 feet draught. Beyond Ottawa is the old Rideau canal, practically untouched since its original completion, and with no more than 4½ feet of water in some of its reaches. In all there are 55 locks and a total rise and fall to Lake Ontario of 509 feet. Third, the Richelieu, comprising the St. Ours' lock and the Chambly canal. These open up a navigation to New York, via Lake Champlain. There are 10 locks in all, overcoming a rise of 79 feet; the size of the locks is 118 feet long by 22½ feet wide by 7 feet draught. Fourth, the Trent, which has not yet been completed, and will be referred to later. Besides uninhabited and valueless, and the broad channels created made it possible to operate boats with a freedom and speed not permissible in narrow canals. The method of construction made it unique in one notable particular; no tow path could be conveniently built, and the historic canal mule never trod its banks. This method of canalization is not, however, without its faults, and there are two grave engineering objections to it. The one absolute necessity of the canal engineer is water, and that in bountiful supply, and of full depth, for on that supply and depth depends the possibility of handling boats with full cargoes in the dry fall months, and the clearest proof of the engineer's lack of foresight and ability is his failure to provide them. Too often they are naturally lacking, and a system of broad, shallow pools, which greatly increase the local evaporation, intensifies this shortage, and such a difficulty is found on the Rideau.

(To be continued).

AN ACETYLENE GAS MACHINE PATENT IN COURT.

The action arose out of the contract made between the respondent and the appellants, dated 7th July, 1897, which recited that the respondent, McMurray, applied for a patent, and was the owner and inventor of an acetylene gas machine. This contained a device for shaking the carbide. By this contract the respondent, McMurray, agreed to sell to the appellants the patent to manufacture said machine, and all improvements



these great systems, there are some minor works such as the Murray canal and the St. Peter's canal, which do not call for special mention.

Considering the canals next as works of engineering we find that two different systems of development have been used in their construction; the one being to overcome the rapids and shoals of the river by an artificial water-way dug around them, and the other to turn the river into a series of vast pools by building great dams across it. Locks are equally necessary in both systems. The Rideau and Trent navigations are constructed by the method of dams, or as it is called by the canalization of the river, while the St. Lawrence and the great part of the Ottawa and Richelieu works are canals proper.

The Rideau was and remains to-day perhaps the boldest and most extensive piece of canalization in the world, and although many of its details have now ceased to be regarded as the best engineering practice, its continued efficiency in service is a high tribute to the skill and judgment of the men who built it, especially when we consider the conditions under which they labored. It was built through an almost unexplored country, without local labor or means of sustenance, and its engineers were practically without data on which to base their designs, for there were no previously constructed works from whose failures and inconveniences they could draw their conclusions. The story of the growth of Bytown reads almost like the tales the modern newspapers tells us of Wady Halfa and the Soudan railways. It was in great measure the lack of labor that made the Royal Engineers adopt the method of dams, for by it they avoided large quantities of excavation which could at that date have been handled only at great cost; the backwater from the dams of course flooded large areas of ground, but that was and patents for said machine, that he might thereafter make in connection with the same, for the price of $3,000, payable $750 by promissory note, within ten days after the issuance of letters patent for Canada, and the assignments for same to appellants, the balance to be paid within two months after the issuance of letters patent for the United States, and the assignment thereof to the appellants. The respondent, McMurray, procured a patent for Canada, but between the date of the same and the issuance of the patent, a new shaking device was substituted for that which was in the machine, at the time of the contract, which the respondent, McMurray, claimed was an improvement on that of the former. The appellants accepted an assignment of it and paid for it. Subsequently a United States patent was applied for, and the United States Patent Office declined to patent the shaker at all, it being then old in the United States, and not the subject of a patent. The appellants thereupon declined to accept an assignment, claiming that the respondent had not fulfilled his part of the contract. The action was tried before the Hon. Mr. Justice Ferguson, whose judgment was delivered on the 20th day of September, 1898, directing judgment to be entered for the plaintiff against the defendants for the sum of $2,250, with interest from the commencement of the action, and with costs, and that the counter-claim of the defendants be dismissed with costs. The defendants appealed to the Court of Appeal for Ontario, and on the 29th day of June, 1899, got judgment, dismissing the appeal with costs. The defendants now appeal to the Supreme Court of Canada. The appellants appealed to the Supreme Court of Canada, and judgment has just been handed down, allowing the appeal with full costs. Biggar & McBrayne, Hamilton, Ont., were for the appellants, and Raymond & Cohoe, Welland, Ont., were for the respondents.

* Calculated on the basis of Dr. Matthiessen's standard, viz: 1 mile of pure copper wire of 1-16-inch diameter equals 13.59 ohms at 15.5° C. or 59.9° F.

These tables are theoretically correct, but variations must be expected in practice.

TEMPERATURE.

C. A. S. E. Executive Office,
Lesson Paper No. 3.

Temperature means the sensible heat in anything, and is measured by an instrument called a thermometer. In general use we find three kinds of thermometers, Fahrenheit's, the Centigrade and Rheamur's. In Fahrenheit's the space between the freezing and the boiling points is divided into 180 spaces or degrees, the freezing point being 32°, and the boiling point being 212°. In the Centigrade the freezing is 0, and the boiling is 100°, the space between them thus being divided into 100 parts or degrees; hence its name, signifying 100 steps. In Rheamur's the freezing is 0 and the boiling is 80°, the space between being divided into 80 parts. The "0" on all these scales reads zero, all above it is plus and all below is minus, viz, a temperature of 10 below zero is written —10°.

You will clearly see by the above that 180° F. = 100° C. = 80° R., and from these we can get rules for comparing degrees of temperature on one scale to those of another. The freezing point on Fahrenheit's scale is 32° above zero, while all other thermometers have the zero at the freezing point; so that if you are given Fahrenheit, to find others from it you must first subtract 32°, but if you are given the others to find F., you should add 32° after the calculation is performed. Examples: What mark on a Centigrade will agree with 90° F.? First, 90° F. — 32° = 58° F. Then as 180° F. : 100° C. :: 58, 100 × 58 ÷ 180 = 32.2° Centigrade. Ans.

What mark on a Fahrenheit will correspond with 124° on Centigrade? The proportion would be as follows: As 100° C. : 180° F. :: 124°, 124 × 180 ÷ 100 = 223.2 + 32 = 255.2. Answer.

All measurements of whatever nature are referred to some conventional unit of its kind: The unit of temperature is one degree F. or the 180th part of the distance on the thermometric

scale, between the freezing and boiling points, under a pressure of one atmosphere.

The unit of heat, or the British thermal heat unit, is that quantity of heat necessary to be added to 1 lb. of water (at or near its freezing point), to raise its temperature 1° Fahrenheit.

The unit of power is 1 lb. lifted 12 inches, or 1 lb. of force acting through 1 foot of distance, and is called the foot pound; 33,000 foot pounds, or units of work done in one minute, make a horse-power.

The unit of work is the raising of 1 lb. through one foot, and a unit of heat is equivalent to 778 units of work.

If water is at the temperature of 60° F., how many pounds of it will it take to condense 1 lb. of steam at 5 lbs. pressure, the resultant water to be 110° F.? It is evident to answer this question you must know how much heat is in the steam. Look up the steam tables in any of your hand-books, and you will see 1151° as the heat of the steam; this we will say is $1151° = T$, and the 110° in the resultant water, is $110° = T_1$.

Then we have $\frac{1150 - T_1}{T_1 - T} = P.$, or pounds of water required.

We now have our calculation to put down in this way:

$\frac{1150 - 110}{110 - 60} = \frac{1040}{50} = 20.8$ lbs. Ans. And in this formula:

T = temperature of the water, T^1 = heat in the resultant water, S = total heat units in the steam, P = amount of T to be used. The formula before any figures are substituted for the letters would stand thus:

$P = \frac{S - T_1}{T_1 - T}$ or in figures $\frac{1150 - 110}{110 - 60} = 20.8$ lbs. water.

Many everyday problems in connection with our engines and boilers can be worked out by the simple rules of arithmetic by understanding the thermal heat unit, and its value in foot lbs. For instance: How many thermal units of heat have we in the following engine, also how much coal will be burned per hour? Diameter of cylinder, 10 inches; stroke, 24 inches; revolutions, 110; and pressure throughout the stroke, 25 lbs. First, remember the value of one thermal heat unit (T H U), and the mechanical force it will exert, viz., 778 foot lbs., then we would have to first find the foot lbs., thus: $10^2 \times .7854 \times 25 \times 2 \times 220 = 863,940$ foot lbs., and $863,940 \div 778 = 1110.46$ heat units used in the cylinder per minute. Second, if one lb. of coal contains 12,000 heat units, and our losses between the furnace and the engine piston, from escaping heat in the smoke-stack, from radiation, condensation and exhaust discharge, is 9-10 of all the heat in the coal, this leaves us but 1-10 for available work, then $12,000 \div 10 = 1200$ heat units available, and $1110.46 \div 1200 = .925$ lbs. of coal per minute; $.925 \times 60 = 55.5$ lbs. per hour, and the h.p. of the engine would be $863.940 \div 33,000 = 26.2$, which would make the coal used per h.p. per hour $55.5 \div 26.2 = 2.1$ lbs.

Latent Heat.—The latent heat of steam is that quantity of heat required to change a body in a given state to another state or form, without changing its temperature. Experiments have shown that 966.6 B T U will convert one lb. of water at 212° F. into steam of the same temperature, hence it takes 966 times as much heat to change 1 lb. of water at 212° F. to steam, as it does to raise the same weight of water from 55° to 56°. The latent heat of steam changes as the temperature under which it is generated changes. If steam is generated under a higher temperature than 212° F., the sensible heat increases, and the latent heat decreases. To find the latent heat of steam at any temperature the following rule is very nearly correct: Let T = temperature of evaporation; latent heat $= 966.6 - .7 (T - 212)$. Example: What is the latent heat of steam if the temperature is 228° F.? $966.6 - .7 (228 - 212) = 955.4$; work the brackets first, then x by .7 and subtract the result from 966.6. Water is composed of millions of molecules, which are always in motion. At 461° F. below zero we would have absolute cold and the water would be perfectly still, at 32° F. there is some movement of the particles, and as we add heat this movement increases, sending the molecules farther and farther apart, thus increasing their speed, and the greater distance between the molecules the greater the space the water will occupy, and this goes on until one cubic inch of water at 212° F. will expand until it occupies 1644 cubic inches of space, the temperature of the whole still being 212° F.; and in causing this expansion we must have added 966.6 units of heat; these have been converted into the work of driving the molecules of water further apart, and can be recovered again if we use the steam where we can apply them, for they all leave the steam as it returns to water. If we take 1 lb. of steam at 212° F. and apply it to heating our building, by the time it is all condensed back to water it has given up 966.6 heat units. In mixing steam and water let W represent the weight of steam, t_1 the temperature of the steam, and w the weight of the water, and t the temperature of the water, and T the final temperature of the mixture of steam and water, and L the latent heat of the steam, we can then formulate this rule to find the temperature of the mixture: Add together the latent heat and temperature of the steam, and multiply the sum by the weight of the steam, to this add the product of the weight and temperature of the water, and divide this sum by the weights of the steam and water; the answer will be the temperature of the mixture. This is a long rule to write down, but in formula it appears thus: $T = \frac{W (L + t_1) + w \times t}{W + w}$

If 14 lbs. of steam at 212° is discharged into 200 lbs. of water at 46°, what will be the final temperature? The weight of the steam $W = 14$ lbs., the latent heat L, is 966, the temperature of it is $t_1 = 212°$, the weight of the water is $w = 200$ lbs., and its temperature is $t = 46°$, we then have

$T = \frac{W (L + t_1) + w \times t = 14 \times (966 + 212) + 200 \times 46}{14 + 200}$. or

$966 + 212 = 1178 \times 14 = 16492$, and $200 \times 46 = 9200$, then

$9200 + 16492 = \frac{25692}{200 + 14} = \frac{25692}{214} = 120.5°$ the final temperature.

QUESTIONS.

If a Centigrade thermometer registers 120, what would be the corresponding mark upon a Fahrenheit scale?

If a Fahrenheit registers 305 what is the corresponding mark on a Centigrade?

How many heat units will be required at an engine piston if the conditions are as follows: Diameter of cylinder, 26 inches; length of stroke, 5 feet; revolutions, 60; average pressure throughout the stroke, 19½ lbs.?

A. M. WICKENS, Executive Secretary.

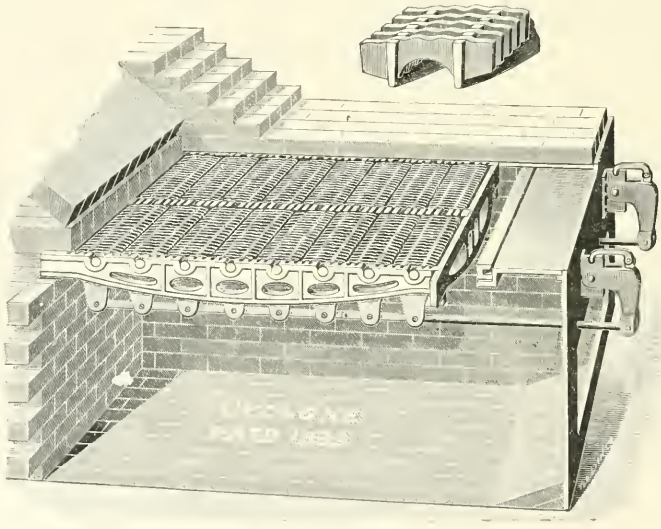
RAILWAY ENGINEERING.

The following criticism of Railway Engineering, by Cecil B. Smith, M.E., appears in a recent issue of The Railway Gazette, New York: In his introduction the author explains that this is intended as a "foundation course only," and that he has endeavored to epitomize his vast subject in such a way that a student or layman without previous knowledge can grasp it intelligently. He undertakes to cover the subject from the very beginning to the end—to tell the considerations that should govern in the general choice of the route and termini; to discuss the relations of grades and curves to future earning power and maintenance cost; to tell how all surveys are made and how roadbed, bridges, culverts and track are built; and finally to give an epitome of railroad law. He undertakes to analyze the difficult subject of train-resistance and to develop the somewhat intricate theory of easement curves. He treats of rails, their sections and chemistry, and of rail joints. All these things and much more he does in 200 pages of 500 words to the page. Obviously so much ground can be covered only superficially in a book physically so small, and the author quite truly says that the "work is not exhaustive, but merely introductory." Naturally, many things are said in a dogmatic and unqualified way that really cannot be accepted as said, without qualification. In the main, however, there is not much in the book that will seriously mislead, and generally it is safe and sound so far as it goes. It is written from the modern standpoint, indicates good theory and practice, and suggests lines of thought and study that may be profitably followed out. In this is its value, rather than as a complete and comprehensive guide to practice in any one branch of the subject treated. Biggar, Samuel & Co., publishers, Toronto and Montreal.

THE CYCLONE GRATE BAR.

There are many ways of economizing in steam production and consumption, but too much attention cannot be given to fuel economy, as the fire box is the source often of very great waste, and a loss in the initial development cannot be made up by any late method of saving. We wish to call our readers' attention to the Cyclone Grate Bar as a means of fire box economy. Presuming the majority of our readers to be interested in methods of economizing fuel, we present herewith some particulars of the Cyclone grate bar, one of the most improved devices for this purpose. In the invention and manufacture of this device, the fact has been kept in view that an enormous waste of fuel is constantly taking place by reason of the escaping of the carbonic oxides of the fuel. This is the result of imperfect combustion caused by imperfect draught, combustion chambers and bridge walls in boilers, together with imperfectly managed fires. While the inventor and manufacturers of the Cyclone grate bar do not claim it to be a smoke consumer, they do claim to reduce by from 40 to 65 per cent. the amount of carbonic oxides escaping through the chimney, which is a proof of its value as a fuel economizer.

It is claimed for this grate that it embodies the three most essential qualities, namely, durability, simplicity and economy of



fuel. An examination of the accompanying illustration will, it is believed, show these claims to be well founded. The air is passed up and through the grate without a break in the current. There are no complicated parts to obstruct the draft and get out of order, while the sifting movement alone with the downward and backward movements cuts the ash evenly and cleanly from the bottom of the fire over the entire surface of the grate.

It is not claimed for this grate that it will grind up clinkers and separate them from the unconsumed coal without losing any of the latter material, but that it is so constructed as to prevent the formation of clinkers, by adding the necessary amount of air through the grate to ensure perfect combustion, and cause the heat to pass out of the fire box as fast as it accumulates, instead of allowing it to remain and melt the coal and form a melted clinker that no grate could break. It has been found in practice that the weight of air required to support combustion is much larger than that theoretically required in order to effect complete combustion. Complete combustion can be obtained with a supply of air not less than 50 per cent. in excess of the quantity necessary for theoretical combustion with natural draft, but it is usual to provide double the quantity of air theoretically required. This grate is especially adapted to burn cheap fuel soft and hard coal, screenings, etc., and for use in marine boilers. Among the claims made for it by the manufacturers are the following:

It is claimed to be the best draft grate in the market; has no rockers and no complicated parts to get out of order underneath the bar or obstruct the draft; the rolling and lifting movement when shaken keeps the air space open and causes no friction on the draft passing through the bar; has ninety per cent. under draft; the frame locks together without bolts, and is easily placed under boiler; will not lock in frame, will not bind in frame; always shakes freely; space in ash-pit same as in ordinary bar, which is four inches; is a perfect bar for all internal fire boilers, no part is in the way to prevent the fireman cleaning out the ashes; the air is passed through and over top of frame—keeps frame cool and prevents warping; all parts of the bar and frame are trussed and bridged; will burn the cheapest fuel with the best results; will evaporate more water per pound of coal than any other device; is level at all times when locked; no bars stick up in fire and burn off; will not break boiler front when shaking. It is manufactured by the Cyclone Grate Bar Company, 10 King street west, Toronto, and is the invention of Henry Truesdell, who has spent the past fifteen years in perfecting it.

Last May, W. Cross, general master mechanic of the Canadian Pacific Railway shops at Winnipeg, Man., caused a test of the relative merits of the Cyclone and another grate to be made in his shops, and reporting thereon to Mr. Truesdell stated that the Cyclone showed up much more favorably than the other, and that the report of the inspector was also favorable, showing that the Cyclone was more easily managed and not as liable to get out of order. The test showed a saving of one ton of coal in each five hours of steaming, an increase in boiler capacity of 25.77 per cent., and an increase of revolutions of the engine 12.3 per minute. Under date of July 25, 1899, the Gurney Foundry Company wrote Mr. Truesdell as follows: "We have examined the Cyclone grate and Mr. Truesdell's ideas of same, and have so much confidence in the simplicity, durability and common sense construction, and find that it covers all the objections of the best grates now on the market, that we have arranged with Mr. Truesdell to manufacture same for our entire line of heating boilers, and have already gone to a very heavy expense in changing our grates, as we believe the advantages in using this grate in our line will more than repay us for this large outlay."

The officers of the Cyclone Grate Bar Company are: John R. Barber, Esq., M.L.A., president; George E. Challes, secretary treasurer, and Henry Truesdell, business manager.

The tannery of Sadler & Haworth, Stanbridge East, Que., has undergone this season costly and extensive alterations in the way of an addition and new machinery, thus doubling their capacity. They are now turning out three hundred and twenty-five hides per week for belting purposes.

BEAVER PORTLAND CEMENT.

BY WM. G. HARTRANFT, ASSOCIATE AM. S. OF C. E.
Designer of the Beaver Portland Cement Co.'s Works.

One of the new industries of Canada is the manufacture of Portland cement, under the Rotary Kiln system of burning, at Marlbank, Ont. The plant is owned by the Beaver Portland Cement Company, limited, with headquarters in the Canada Life Building, Montreal, Que. This company purchased on Nov. 1st, 1898, the property of the English Portland Cement Company, limited, at Marlbank, and their new plant was erected and in operation, June, 1899.

The deposit of raw materials is at the site of the works, and consists of a dry lake of about 150 acres, on which there is a deposit of marl, varying from six to thirty feet or more in depth. This marl contains from 97 to 99 per cent. of carbonate of lime, and underlying this marl is clay suitable for the making of cement, to the depth of from three to fifteen feet.. Previous to the purchase of the deposit of raw materials at Marlbank, a large number of marl deposits, situated in different parts of the Dominion, were thoroughly examined and analyzed, and were found to contain a large amount of extraneous matter, which rendered them less suitable for making a uniform quality of cement, but the deposit owned by this company is so singularly pure and free from all objectionable ingredients that a perfect and uniform quality of cement can be regularly produced therefrom.

The high grade Portland cement of to-day is essentially a tri-calcic silicate, produced by burning a mixture of finely ground lime and silica to incipient vitrification, and pulverizing the resulting clinker. The burning is accomplished in either what is known as the stationary kiln method (intermittent or continuous) or in the rotary kiln method. With the use of the stationary kiln, the raw materials are made into bricks and dried; then placed in kilns with the fuel (coke or coal). The burning is then largely out of the hands of the manufacturer, and depends on the draught and other incidents beyond his control; the result is a varying product more or less over or under burnt. If this improperly burnt material is ground with the good clinker, the result will be a cement irregular in quality. The under burnt and over burnt material varies under this process of burning from 3 to 25 per cent. of the output of a kiln, and if sorted out and discarded by the manufacturer, it is done at a considerable loss.

With the rotary kiln process of burning, the raw materials are conveyed into the kiln in powdered form, if using the dry process, or pumped in if using the wet process. The kiln is a large steel shell, six feet in diameter and sixty feet long, lined with fire brick, and erected on a slight angle. It is built to revolve at the will of the operator, through the use of a variable speed regulator, from one revolution in thirty seconds, to one in every four minutes. The raw material is fed in at one end, and the fuel, oil, or pulverized coal being applied at the other end. The amount of fuel supplied to the kiln is also regulated by a variable speed device, so that by this process, over burning or under burning of the clinker is practically unknown, as the burning is absolutely under control at all times. The operator by the use of specially prepared eye glasses, watches the burning, and if the heat in the kiln is reduced from any cause, he retards the discharge of the clinker by slowing down his kiln, and then increasing his fuel. Or, on the other hand, if the heat in the kiln becomes too intense, he increases the speed of the kiln, and reduces the fuel; either of which is accomplished by pushing a lever close at hand. Although this rotary kiln process for the manufacture of high grade Portland cement is not new in other countries, it remained for the Beaver Portland Cement Company, limited, to introduce it into Canada. This process of burning was originally patented by Ransome, of England, and was first installed about 1885 in the Gibb's Portland Cement Works on the Thames, where it was not a financial success. Mr. Jose de Navarro purchased the rights to use the process in the United States, and it was in that country that the process was improved, and brought up to the present state of perfection. The great strides made under this system of burning in the United States can be noted by the following table:

	1890 Bbls.	1893 Bbls.	1896 Bbls.	1898 Bbls.	1899 (est.) Bbls.	1900 (est.) Bbls.
Rotary Kiln.....		149,000	633,370	2,170,782	3,500,000	5,000,000
Stationary Kiln...	350,000	441,653	950,653	1,521,502	1,500,000	1,500,000
Total.....	350,000	590,653	1,543,023	3,692,284	5,000,000	6,500,000
Per cent. of total burned in Rotary Kiln.....	0	25.2	41.0	58.8	70.0	76.9

The reason of this increased use of rotary kilns is due to the engineering profession to-day requiring high grade Portland cement, uniform in quality, and to get this result, the raw materials must be uniformly hard burnt. It is also worthy of note that two of the largest and best known German manufacturers, the Alsen Portland Cement Co., and the Henmoor Portland Cement Co., are now erecting factories, in which the rotary system of burning will be used. Two rotary kilns have been in successful operation at Marlbank since June, 1899, and all the cement manufactured by the Beaver Portland Cement Company, limited, during the past season, has been distributed throughout the provinces of Ontario and Quebec, large quantities having been used in street pavements in the larger cities and towns, and also in the construction of dams, etc., where nothing but a high quality of cement was required to meet the specifications. The company has received from the various contractors and dealers, who have used the "Beaver" brand, numerous testimonials, which amply testify to its being a uniformly high grade article; all of which is amply borne out by the following tests made in various laboratories:

Aug. 4th. City of Ottawa, N. J. Ker, assistant city engineer, one inch briquettes, 7 days old.....607 lbs.
Aug. 19th. C. A. Ry., E. J. Chamberlain, gen. manager, Ottawa, one inch briquettes, 7 days old.....523 lbs.
Aug. 28th. Lathbury & Spackman's laboratory, Philadelphia, one inch briquettes, 7 days old.....795 lbs.
Oct. 12th. McGill University, Montreal, one inch briquettes, 7 days old .....705 lbs.

The company is now installing three more rotary kilns, which, in conjunction with the two kilns already in operation, will give their works a capacity in the neighborhood of 1,000 barrels per day, and will make them the largest producers of Portland cement in the Dominion of Canada. The company has no hesitation in putting its product forward as the highest grade of Portland cement manufactured, as well as the most economical for making artificial stone.

GOOD ROADS.

Upon the invitation of the York County Council, upwards of fifty gentlemen from various parts of Ontario, nearly all of them members of some municipal body, met in the York County Council chamber, Toronto, December 11th, in convention for discussion of the good roads problem. The chief feature under discussion was the assumption by counties of the construction and maintenance of certain main travelled roads in the county, the funds to be rased by a general taxation or by debentures. At the commencement of the afternoon session, W. C. Lundy, chairman of the Special Committee of the County Council, who had the matter in hand, was elected to the chair, while County Clerk Ramsden was chosen secretary. Mr. Lundy, in his opening address, after thanking the delegates for the honor conferred upon him, briefly stated the history of the road question in York county, from the toll gate days to the present, when the municipalities charged with their maintenance have failed to keep them up. At the June session of the council it had been proposed to take over some of the roads again. A committee was appointed to collect information, but so much had been received that it was felt advisable to hold a convention to discuss it.

A. F. Wood, ex-M.P.P., Madoc, Ont., then gave an address on the experience of the county of Hastings in dealing with roads. Mr. Wood sketched the history of the treatment of the roads in that county for the past forty years, beginning with the toll gate system, which was abandoned on account of the abuses which accompanied it. After several plans had been tried the county finally undertook to construct and maintain a proportion of the chief highways, constructing them of gravel. A Gravel Road Committee and a road superintendent were appointed to look after the work, employ the necessary labor

and purchase the necessary material. The result, Mr. Wood said, had been most satisfactory, and had resulted in a great saving by reason of the scientific methods of construction which experience led them to adopt. When Mr. Wood had concluded, he was besieged with questions, to which he replied fully.

J. F. Beam, Black Creek, Ont., read a spirited paper on Good Roads, Principles and Results. After referring to the failure of the statute labor system, he spoke of the example in the county of Hastings as it had been outlined by Mr. Wood. He was in full sympathy with the project of county maintenance of main roads, and expressed the strong conviction that the cities, which drew so much wealth from the county, should pay their share of the cost. He pointed out the example of a number of States where the Government gave substantial grants for the maintenance of public roads. The convention adjourned a little before five to allow the delegates to visit the new city hall.

When the evening session opened the first business was the appointment of a Committee on Resolutions, consisting of one delegate from each of the counties, represented as follows: Messrs. Harold Eagle, Haldimand; Col. McLean, Durham; J. B. Calder, Wentworth; M. Richardson, Grey; J. F. Beam, Welland; H. W. Fowlds, Northumberland; Robert Byrnes, Victoria; L. Kaufman, Oxford; W. H. Pugsley and W. C. Lundy, York; D. H. Moyer, Lincoln and F. W. Wilson, Lambton.

Andrew Pattullo, M.P.P., Woodstock, Ont., the organizer and first president of the Good Roads Association, followed. The fact that so many representatives of the people had gathered together, he said, was in itself a most hopeful sign for the success of the movement. It showed that public attention had been considerably aroused when these legislators met to seek information on the subject. The work of Mr. Campbell was appreciated at home, and now his reports were read and appreciated in other provinces and several European countries. Good roads were cheaper at any cost than bad roads. The transportation problem was the greatest one in Canada, and our duty now was to pay attention to our rural highways. He knew of no service or direction in which the councils could do so much good as to take hold of the management of the leading roads in their respective counties, and employ trained men to keep them in proper state of repair. Their example would be followed by the township councils. The present Legislature was favorable to road improvement, and he suggested that the cause could be assisted by the Government guaranteeing the bonds by which the counties borrowed money for the purpose, whereby the latter could get funds at probably a half lower rate of interest. Statute labor ought to be abolished; it was a relic of barbarism. He favored optional legislation by which municipalities could, if they wished, abolish the system. In conclusion, Mr. Pattullo suggested that the convention adjourn instead of dissolving, and that its recommendations be sent to the municipalities to be discussed in the coming elections and also at the January meetings of council, after which it would have greater effect.

John A. Ramsden gave an instructive paper on "Reforestry." As a result of the clearance of this country of its forest by the pioneers snow and dust were now free to fly over the roads, rendering travelling disagreeable both winter and summer. The planting of trees both in rows and in blocks and belts would have a very beneficial effect in protecting the roads. Mr. Ramsden recommended that the attention of the Legislature be specially drawn to this matter.

At the second day's meeting addresses were given by Hon. E. J. Davis and A. W. Campbell. A. E. Woods, of Madoc, took the chair and gave many valuable suggestions. Hon. E. J. Davis, after speaking of the early days, went on to speak on the transportation problem and the saving to farmers in good roads. Especially were they necessary for the cheese and butter industries, so that milk could be got easily to the factories. It would also help the new system of postal delivery by the farmers. On behalf of the Premier and the Government he expressed appreciation for the efforts now being made in the direction of good roads, and gave a hint that should a request be made for Legislative aid the request must be a very reasonable one to be granted.

A. W. Campbell, the Provincial road instructor, dealt with the practical side of road-making, and told the delegates what could be done if they had the money to spend in that direction. He compared the roads of Hastings with the dreadful roads of York county, and went on to show that a large amount of money expended in road-making is absolutely wasted.

The afternoon was taken up in discussing the report of the Committee on Resolutions, which went through a great sifting process before being adopted. It inculcated the following principles when finally passed: (1) The assumption of main and leading highways by county councils. (2) Provincial aid towards making and maintaining leading highways assumed by county councils in a leading road system. (3) Legislative supervision of electric railways, more especially with a view to enabling suburban railways to have access to markets or other destinations through cities or towns which have granted franchises to railroads.

These main principles will be enlarged upon by a committee appointed to prepare them for publication in pamphlet form. The Provincial Minister of Agriculture will be asked to bear the cost of printing, and the pamphlet is to be circulated among the municipal officers of the province. This committee will consist of C. E. Lundy, York; M. Richardson, Flesherton; James Graham, Lindsay; D. H. Moyer, Lincoln; W. H. Pugsley, York; M. Buchanan, Ingersoll, and the secretary, Mr. Ramsden. Among those present were: H. W. Foulds, Northumberland county; Lieut.-Col. McLean, Port Hope; B. W. Kiteley, Sharon; Thomas F. Wallace, Woodbridge; J. B. Calder, E. Kenrich, Wentworth county; M. Richardson, Grey county; Andrew Pattullo, M.P.P., Woodstock; W. J. Stark, Stouffville; R. Maitland Roy, Hamilton; W. H. Pugsley, Richmond Hill; Andrew M. Miller, East Toronto; J. L. McCullouch, East Toronto; James McDougall, Toronto; F. Beam, Welland; C. H. Gill, Toronto township; Harold Eagle, Haldimand county; R. G. Gibson, Toronto; J. C. Stokes, King; J. W. Brown, Stouffville; R. Norman, York; James Lee, Scarboro'; John A. Boad, North Gwillimbury; John Gardhouse, Etobicoke; F. W. Wilson, Petrolia; Wm. C. Grubb, Etobicoke; S. Baker, Whitchurch; J. A. Duff, Toronto; F. K. Reesor, Markham; P. G. Savage, Markham; T. H. Sylvanus, Hamilton; A. W. Campbell, provincial road instructor, Toronto; Henry Duncan, J. C. Miller, York; W. E. Switzer, Omemee; Robert Prynes, Lindsay; George Johnston, Cannington, and H. S. Cane, Newmarket.

NEW SHOPS OF THE CANADIAN RAND DRILL CO.

The extensive shops of the Canadian Rand Drill Co., Sherbrooke, Que., were opened December 9th for inspection, and from two to five o'clock there was a large attendance of citizens, who feel an interest in the progress and success of these important works. F. Lewis, president of the company; S. W. Jenckes, vice-president; A. Sangster, and others, received and showed the visitors about the premises, where nearly one hundred employees were busy at various kinds of work. After inspecting the shops and machinery the visitors were entertained with refreshments in the offices. The main shop is a brick structure, 95 feet wide by 200 feet long, well lighted from the sides and top which is filled with the latest and best patterns of wood and iron working machinery, which are to be augmented by others shortly. There are also three wings each 35 x 40 feet, the first being the office, two stories high, finished partly in wood with oak furniture, the lowest story being used for the office proper, and the upper flat for the draughting room. A fire-proof vault extends up through both stories. A second wing embraces the power house, fitted with a 90 h.p. engine, and the foundation for a large air compressor soon to be placed in position to supply the motive power for the electric crane, and the circulating pumps to supply the hot water system with which the building is heated. The third wing embraces the blacksmith shop, which will have four forges, the smoke of which will be taken by a 40-inch exhaust fan. There is also a large store house, 40 x 85 feet, west of the main shop. The C.P.R. has a siding beside the store house, and a track laid into the main shops for the purpose of handling the machinery with greater convenience. Stone foundations are laid for the heavy lathes, engines, etc. One side of the shops will be used for the compressor work and the other for pattern, drill and tool work. The heating will be done by the Eynon-Almiral system of New York.

THE ARMSTRONG PLANER TOOL.

The Armstrong planer tool is especially adapted for the economical use of self-hardening steel in planer and shaper work.

This tool is, it is stated by the makers, pronounced by all who have seen or used it to be a money-saver. It is a decided and practical extension of the Armstrong idea. The shank is drop forged of steel and is case hardened. The cutters are of self-hardening steel, rectangular in shape and of stock sizes. By means of grooved seats, into which they are placed, the cutters may be quickly adjusted to any desirable angle, and at the same time so locked into position as to render slipping impossible.

Armstrong Bros. consider rectangular shaped steel preferable to square for a planer tool cutter, as it is stiffer and at the same time admits of being ground with more side rake than square steel; cutters of rectangular shape will also admit of sharpening oftener than square without reshaping the point. The Armstrong planer tool can be used either right or left hand (see Fig. 1), and when desirable or necessary, as for instance, when cutting a keyway, it may, by simply reversing the cutter and turning the tool around, be transformed into the equivalent of a "goose neck" tool (see Fig. 2). One of these tools equipped with an assortment of properly ground cutters will, it is said, effectively equal a complete set of solid forged planer tools. Fig. 1 shows the Armstrong planer tool at work in close corners, giving a good general idea of clearance obtained. It shows also a few of the angles at which the cutter can be set. A job similar to one shown above could be finished with the planer tool, without shifting position of the work on bed. Figure 2 shows the Armstrong planer tool cutting a keyway with the cutter reversed and the tool turned around, thus throwing the cutting point behind centre of tool and practically working as a "goose-neck" tool.

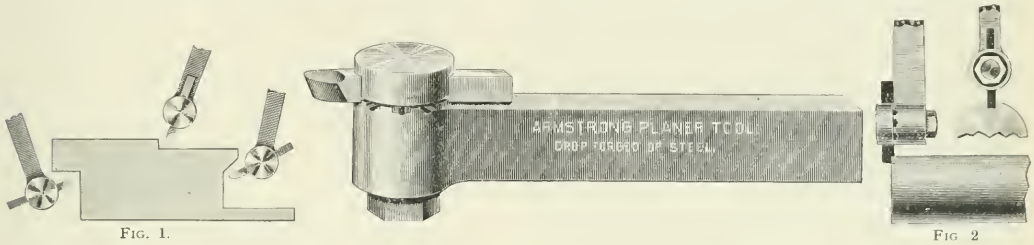


Fig. 1. Fig 2

EXPLOSION AT THE DOMINION CARBIDE WORKS, OTTAWA.

(From a Correspondent).

The official investigation into the cause of the fire and explosion at the Dominion Carbide Works, Ottawa, in Nov., has resulted in the clearing away of a great deal of ignorance and prejudice that existed on the question of calcium carbide and acetylene gas. The reports telegraphed over the country were highly colored, and contained so many misleading statements as to be utterly unreliable. Of the eighteen men hurt in the explosion, one only is permanently injured, by the loss of one of his eyes. The majority of the others were at work again in a few days after the accident. The jury selected to investigate the question was composed of hard-headed, shrewd business men. Their finding was as follows:

1. We find that there has been no evidence before us that throws any light upon the origin of the fire, which started in the story above the carbide factory.

2. As to the cause of the explosion we have attentively listened to the evidence of all the witnesses who were present at the time of the fire, as well as to the testimony of the various experts, and believe that it resulted from the joint action of steam and gas, but whether the latter was acetylene or water gas, resulting from the water coming in contact with the intensely heated material, causing decomposition of the water, the evidence is not made clear.

3. We find that the manufacture of calcium carbide is considered hazardous under certain conditions, and that in England strict regulations are enforced, both as to its manufacture and storage. It was also shown in the evidence that there is danger if it is not under strict control in its manufacture and storage. Further, that the essential conditions, which should be enforced, are a fire and water-proof building. And when these conditions are observed, no danger is likely to result in its manufacture.

4. We would recommend that the pigs after coming from the crucibles and cooling should in all instances be removed to a separate room and compartments.

5. We also find that the city by-laws, dealing with manufactures of this character, have not been observed, and would urge that hereafter the same be strictly enforced.

6. We further find that the authority of the chief of the fire brigade was not accepted by the employees of the local firms having private fire appliances, and if the city by-laws do not place the chief in absolute authority at all fires within the city limits, they should be so amended as to make his authority supreme.

The verdict was evidently a compromise between the jurymen, who paid particular attention to the evidence of men who were not experts, and those who were influenced by the scientific and practical testimony given. Such scientists as Thomas Macfarlane, Dominion Analyst, Inland Revenue Department; Prof. Shutt, Analytical Chemist, Dominion Experimental Farm, Prof. McGill, of the Geological Survey, and the practical men who handle carbide every day, testified that it was not possible to generate acetylene from red hot carbide. The evidence also proved that when the gas began to generate from the cold, broken carbide on the floor, by the water dripping down on it, it was at once fired by burning wood dropping on it from the ventilating shaft, and was consumed as fast as made, so that the explosion could not have come from that source.

All agreed that the explosion occurred within the crucible. When it is considered that the crucible contained a thousand pounds of molten carbide, covered and surmounted with an infused mixture of powdered lime and coke, between it and the iron of the crucible; that on this porous material a large quantity of water poured down from the ceiling alone, one can easily understand how rapidly the water will be developed, by contact with the molten carbide, into a very high pressure steam with an irresistible explosive force.

There is no doubt whatever in the minds of mechanics, foundrymen and other practical men, that that is precisely what occurred. The City Council, acting on the coroner's finding, has issued instructions to prepare a by law to regulate the manufacture and storage of carbide. The Dominion Carbide works are being rapidly prepared to comply with the regulations suggested by the jury. The factory is being made absolutely fire-proof, with steel girders and iron roof. It will be ready to resume operations this month, with a capacity of four to six tons per day. The Bronson factory, with a capacity of fifteen tons per day, is expected to commence smelting in February. At present such a carbide famine exists that many lighting plants have had to shut down. Once the Ottawa factories get running, there will be no more shortage.

Thos. Cantley, secretary of the Nova Scotia Steel Co., of this town, is at present in London, Eng., completing plans for the purchase of the General Mining Association coal mine at Sydney, C. B., says The New Glasgow Bulletin, recently.

AS OTHERS SEE US.

Biggar, Samuel & Co.:

Enclosed find postoffice order for $2. payment for your valuable paper, The Canadian Engineer, which pays to July, 1900. This should have been paid long ago, as the price is small considering the valuable information your paper contains.

JAS. FORDYCE,
Supt. W. W. Dept., Guelph.

Canadian Engineer:

Enclosed find my subscription for this present year. I have found great pleasure in consulting your excellent paper on all matters relating to engineering plans and designs, and especially on those articles relating to railroad building published this preceding year. Wishing your paper every success, I remain, ALEXANDER ROY, Wabigoon, Ont.

I miss The Engineer when it does not come.

J. F. MURPHY, Windsor, N.S.

In response to your post card just received, please find enclosed $1 in payment of Canadian Engineer, up to February next. I think you give good value for the amount.

JAMES B. HEGAN,
Dept. of Public Works, Charlottetown, P.E.I.

Gentlemen:—Having had space for the past twelve months in The Canadian Engineer of Toronto, it has been productive of many enquiries, and resulted in a satisfactory business for us. We can recommend it to any manufacturer desirous of introducing his goods to the Canadian trade, as without exception it stands at the very head of publications of its kind in Canada, and in fact is the only desirable medium through which to reach the machinist, supply and general hardware trade. We cheerfully speak of the satisfaction given us during the term of our subscription, and confidently recommend it to any firm desiring to reach the Canadian trade.

DIAMOND SAW & STAMPING WORKS.
Manufacturers of Hack Saws, etc., Buffalo, N.Y.

Gentlemen:—We have found very valuable information in "Practical Man" column; many of them worth much more than a year's subscription. Enclosed find $2, amount of our subscription. S. VESSOT & CO.,
Founders and Machinists, Joliette.

Enclosed is $1. The Engineer is really a gold mine of good assorted news, and most interesting and valuable. Mr. Watson's sanitary letters are grand. Your good management has made The Engineer a power in Canada, and I feel proud of it.

J. D. RONALD,
Mnfr. Fire Engines, Brussels, Ont.

PUMPING MACHINERY.*

BY C. E. MORGAN.

Perhaps the engineer in his varied experience with machinery has given but little thought to the important work that a steam pump is called upon to perform in connection with his boiler plant. I would commence by stating that although it is possible to feed a boiler with other appliances the steam pump undoubtedly is the best all round commercial article. I do not propose to enter into the question of economy of the steam pump as compared with other means of feeding boilers, such as injectors and power pumps, these no doubt have their uses as auxiliaries, and perhaps in some cases it is advantageous to use a power pump where the engine or prime mover is constantly running, as by so doing the water is pumped practically with the economy of the engine. A boiler feed pump is called upon frequently to handle water at various degrees of temperature, and this being the case certain mechanical features in its construction have to be considered. For instance, in handling water at normal temperature say 70 degrees, the ordinary inside plunger type of pump is perhaps all that is desired, whereas should the water reach a temperature of 212 degrees the conditions are different, inasmuch as the temperature of the feed water expands all working parts of the pump and it becomes necessary to have the machine so arranged that the water piston can be adjusted to meet these conditions. This feature is easily taken care of by using a special boiler feed pump, so constructed that its plungers are externally packed. This enables the engineer to immediately discern any leak which may have taken place, and to satisfy himself that the pump is fully efficient at every stroke. Some engineers have raised the objection to a certain amount of friction which is set up by the external adjustment of the plungers, but if the machine is properly made with deep well fitting neck bushes and glands, this feature is not of very much consideration, as under absolute tests the friction set up is a very small percentage.

*A paper read before C. A. S. E. No. 1, Toronto.

Difficulty is often experienced when pumps are working on very hot water, but in cases that have come under my own notice, I have usually found that the trouble has arisen by the machine being placed in a position where it would practically have to raise the water by suction, while, in place of this, it should gravitate, as the formation of a vacuum in pump would be immediately filled by the vapor from the hot water, and would consequently interfere with the proper working of the machine. It is also very important to have valves of proper materials for handling water at high temperatures. Machines are frequently condemned when really the working parts are at fault.

In steam plants it sometimes happens that in feeding boilers the pumps used are much too small for the work required. In making a choice of a steam pump for feeding boilers it is well to have it of sufficient size so that it will do its work easily. For pumps having a 4-inch stroke it is possible to run them to 150 strokes per minute; 6-inch stroke, 130; 8-inch stroke, 120; 12-inch stroke, 100; 16-inch stroke, 85, and 18-inch stroke, 80. You will note that these are maximum speeds, and for boiler feeding purposes the machines should operate at about one-fourth of the above speeds. In estimating the capacity of the boiler feed pumps the following formulae is used:

$$\frac{\text{H. P.} \times 30 \times 28}{\text{Speed in inches} \times 60} = \text{area of high cylinder.}$$

This is for a single cylinder piston pump. Of course for a duplex it would be one-half this, and for a triplex so much. In very large steam plants the compounding of boiler feed pumps is possibly a move in the right direction, resulting in a considerably more economical consumption of steam. It is very probable that a compound steam boiler feed pump will shortly be introduced, which will not be very much more expensive than the ordinary high pressure machine, and would certainly be well worth the difference in cost. We have machines of this class operating to-day, with very good results.

These compound pumps are made of either the single or duplex type; some engineers preferring the duplex machine, and others favoring the single. So far as economy is concerned, possibly the single pump is the most economical, as there are less clearance spaces to be filled, and consequently a more economical use of steam. Another feature which the single pump possesses over the duplex is that in its length of stroke it is uniform, while the duplex pump invariably short strokes on either side, which further increases waste in the use of steam. The duplex pump, however, is perfectly positive in its steam end, while the single pump has been known to give some trouble in this respect. But this is usually due to the inferior construction of the automatic valve gear. There is no good reason why a steam thrown piston valve should not be equally as positive in its operation as the positively moved one, if the ports, both steam and exhaust, are properly proportioned, and made strictly to templates. I think the field of boiler feed pumps has been pretty well covered, and I will now for a few minutes take up the condenser question. The question of economy is being studied more closely to day than was the case some few years ago and the manufacturers are asking for the most economical steam plant that can be installed. In order to achieve these results, condensing engines of different styles are being called for, and independent condensers of many types are being made to day. The horizontal single and duplex form, and the vertical single and double acting duplex or twin type, or the rotative type. The choice of any one of these condensers is regulated by the size of the plant, and for ordinary small plants possibly the horizontal single type of condenser is the cheapest. When

large units, however, have to be considered, the most efficient and economical type of air pump and condenser should be installed.

Undoubtedly the most efficient type of air-pump to-day is the single acting vertical, its high efficiency being due to the fact that all clearance spaces can be practically dispensed with, and being of the single acting type the velocity of flow is not checked by diversion. Being provided with foot and bucket valves, and these valves always covered with water, there is very little clearance space.

The lack of efficiency in the double acting horizontal or vertical type of pump is largely due to the reverse of some of the above conditions, as by the failure of the valves in closing, and also a large space between the suction and delivery valves. The speed at which air pumps can be operated depends upon the valve area which they contain. This in a great many cases, is very much contracted, and accounts for the unpleasant noise which air pumps are sometimes known to make on board steamers. If this valve area could be increased the pump would work sometimes quieter.

Beyond doubt the most economical style of air pump is the rotative vertical type, as it enables you to use steam expansively. Its first cost, however, is very much greater than the direct acting vertical type, and on account of its rotative action it is considerably more expensive to maintain. I think it is possible to construct an air pump of a design which will allow of the valve area being very largely increased, and consequently a higher speed made practicable. This experiment is at present under test, and we have every reason to believe it will prove of great commercial value.

For the practical engineer, perhaps a rule which is used for the proportion of an independent air pump and condenser for certain sized engines would be well to remember. The data which is required before being able to estimate, is the class of engine which is being used, the pressure of steam supplied the engine, point of cut off, and the number of revolutions, or piston feet travel per minute.

The formula which is used for the proportioning of independent air pumps and condensers and engines of various sizes is written thus:

$$\frac{2 \times A \times S \times C \times N \times W}{15\ F.} = \text{Area of air pump.}$$

A = Area of H. P. steam cylinder, in inches.
S = Stroke " " " " "
C = Cut-off " " " " fraction of stroke.
N = Number of revolutions of engine per minute.
W = Weight of 1 cu. ft. steam at initial steam pressure.
F = Speed of air pump in feet per minute.

I have not thought it well to occupy your time with any other class of pumping machinery but what we are familiar with, and may say that the pumps which are used for mining, pumps that are used in pulp and paper mills, and the triplex power pump, and special pumps for special purposes have not been touched upon in this paper.

SOME EXPERIENCES WITH PORTLAND CEMENT.

BY W. K. ELDRIDGE, CITY ENGINEER, OF LAFAYETTE, IND.

(Continued from last issue).

But there is another danger attending the use of Portland cements, as now made, owing to their adulteration with slag cements, or possibly ground slag itself. A great and growing industry in this country as well as in others is the manufacture of cements from blast furnace slags, going under the name of "Portland" cements. Blast furnace slag being a waste product its use for such a purpose renders possible the making of a cheaper cement, which, if as good as the regular make, should not be kept out of use. And yet, for sidewalk purposes, any engineer having experimented with this material will not consent to take any more of it in sidewalks. At the same time, it has its legitimate uses, and when submitted to the regulation tests it rarely fails to fulfill all the standard requirements, and a contractor standing squarely on his rights and dignity can compel you to let him use it. So far this season I have barred it out of sidewalks by insisting that it is not a true Portland cement, but with the expectation some day of having my ruling contested and beaten. There are some slag cement walks which appear good and durable, made of a certain brand, the manufacturer explaining that he puts the slag through a roasting process before mixing and grinding, but I fear that the engineer who accepts even this cement too trustingly would lay himself liable to a roasting also. But if there be any distinction between slag cements for sidewalk use there is certainly so far no prescribed test by which this distinction can be determined. Ground basic slags are so unstable in their composition that they have to be kept tightly corked in the laboratory to hold them from the continuous disintegration which goes on during exposure to the air. In underground work, such as street and other foundations, slag cements seem to give good results and cheapen cost, but in the case of sidewalks, a granulating and rubbing off of the surface seems to be continually going on, as in some cases now under my observation, which cannot, I believe, be attributed solely to the traffic. There are so many different constituents in slags, and so many variations in their relative proportions in different slags, that a uniform and reliable product for such extreme service as sidewalk use can hardly be expected. It is only occasionally that ores and fluxes employed in blast furnaces will produce slag suitable for cement. Also, all such slags are devoid of hydraulic properties unless a change in their composition be effected.

A common use for slag cements which our experiments are pointing to is as an adulterant for regular made Portland cement by which the cost of production may be cheapened and output increased when demands are pressing. This was first noticed in some of the German cements, from which quite an appreciable amount of finely comminuted metallic iron or steel may be extracted by a common magnet, and the same thing was more recently found in two brands of American-made cement, amounting, even by this rough-and-ready method of analysis, to about one part in one thousand. It may be that the particles of metal themselves are not injurious except to the pocket, the purchaser buying one barrel of useless metal and 999 barrels of cement; but if such a complex and mysterious substance as basic slag be present, the risk remains of some one or more of the elements affecting a structure, such as a sidewalk exposed to all the effects of heat, cold, water, frost, etc. A sample of acknowledged slag cement showed one part in about 300 of metallic iron, so that the possibility remains of a Portland cement being adulterated with about 30 per cent. of slag, and yet pass all the customary tests, and under the usual specifications would have to be accepted. A statement of the foregoing was sent to a prominent New York engineering periodical, whose editor gravely advanced the explanation that the presence of iron could be accounted for by the wear of machinery. But since many cement plants produce 1,000 barrels per day, any set of machinery that can make a daily contribution of 400 pounds of its substance to its product must, like the widow's cruse of oil, have the miraculous faculty of self-restoration between days.

A series of simple tests for slag adulteration may be carried on by anyone with slight chemical knowledge and little paraphernalia. The presence of metallic steel is a sure indication, as no such particles should be present in an honestly made cement. Shake a little of the suspected cement in a glass of water, and stir with a bar magnet of fair strength. On examination, the pole of the magnet will be found more or less covered with minute sparkling particles of steel or iron, easily distinguishable under an ordinary pocket magnifying glass, and there will also be seen minute balls or agglomerations of magnetic material of a nondescript character, which nothing but slag ever contains. If a solution of the cement with hydro-chloric acid be made, there will usually be some insoluble residue; also, a strong odor of sulphuretted hydrogen, betraying compounds of sulphur of a possible dangerous character when exposed to the air; carbonate of lime, as betrayed by effervescence, may be present or absent. The presence of phosphorus, another element of basic slag, may be ascertained by the molybdate method as laid down in the publications of the official agricultural chemists, and noting a yellow precipitation. Bulletin 46, Chem. Div. U.S. Dept. Agriculture. We have one sidewalk laid about fifteen months ago, using a German Portland cement of high reputation and corresponding price, besides sustaining a high physical test, which lasted about

ten months before showing signs of cracking, and is now in an active stage of progressive disintegration. Securing some fragments of the top course, I had the foregoing tests made for slag, and in spite of the admixture with sand which had been made in laying the walk, all the characteristic reactions were obtained except the odor of sulphuretted hydrogen, which might be accounted for by the total change of the sulphides in that length of time. On crushing the mixture and testing with the magnet, we were still able to extract bright metallic steel, though much of what was originally there had evidently been oxidized. Carbonate of lime was present in force, also the sulphate of lime, and phosphoric acid. In fact, if we had continued farther, we should doubtless have found that if there were anything in the world that ought not to be in a cement, it would be found in that cement. It has been said that the Germans waste nothing; if their slag is high in phosphorus, they make a fertilizer; that which is low in phosphorus they use in cements.

However the doctors like it, there is very little satisfaction to an engineer in holding a post-mortem, but the result of this one on the defunct sidewalk in question might be stated in this form: Dissolution caused by excess of free lime contributed by basic slag adulteration, but concealed and true prognosis prevented by the presence of calcic sulphate, complicated with ferric oxide, various sulphides, phosphorus and other undiscovered components of blast furnace slag. It is no doubt a legitimate business to engage in the manufacture of slag cements; but to use the same as an adulterant is false and fraudulent and full of danger to the user in his work.

So far, the season has been too busy to afford much time to be spent on these matters; but a collection has been made of various samples, briquettes of different ages, etc., and we hope that much information may result from more thorough and leisurely examinations that will be of much benefit to the controllers of public works, and by developing methods for practical use will supplement the present standard of tests in the direction in which this standard now fails. But it will be, I believe, of greater benefit if this investigation be undertaken by a number of laboratories, totally disconnected from any manufacturing influences, whereby one may supplement another, errors be mutually corrected, and the increase of knowledge by the competition of mind with mind be fully obtained. Until this be done, I think we may all join in the sentiment of a cement expert, who remarked that the more he learned about cements, the less he was willing to swear to.

LITERARY NOTES.

The annual calendar of McGill College and University for 1899—1900, contains some 350 pages of information about this wonderful seat of learning—the greatest in Canada.

We have Volume IV., No. 5, of the Journal of the Western Society of Engineers, containing papers, discussions, abstracts, and the proceedings of the society. Published by the society in Chicago.

The American Sewage Disposal Company, of Boston, U.S., has issued a very neat pamphlet, which contains some details as to the works it has undertaken and a full statement of the qualifications of John M. McClintock, A.M.C.E., the president and resident manager of the company.

The Slide Valve, simply explained by W. J. Tennant, A.M., M.I. M.E., revised and enlarged by J. H. Kinealy, D.E., professor of mechanical engineering in Washington University, is a cloth bound volume of 75 pages, whose profuse illustrations give a very accurate idea of this difficult mechanism.

We have received a copy of the third edition, just issued, of Gas, Gasoline and Oil Vapor Engines. This is stated to be a new book, on the subject, descriptive of their theory and power, illustrating their design, construction and operation for stationary, marine, vehicle, and motive power. This book is by Gardner D. Hiscox, M.E.

Up to date, the Canadian Engineer has received calendars for 1900 from the following companies and firms: Morton, Phillips & Co., manufacturing stationers and printers, Montreal; Royal Victoria Life Insurance Co., Montreal; National Assurance Co., of Ireland, Montreal and Toronto; the J. C. McLaren Belting Co., leather belting and mill supplies, Montreal and Toronto; Alex. Bremner, drain pipes, Portland cement, fire bricks, etc., Montreal; the Pope Manufacturing Co., bicycle manufacturers, Hartford, Conn.; Hamilton Times, Hamilton, Ont.; London Assurance Corporation, Montreal, P.Q.; Union Mutual Life Insurance Company, Toronto. These calendars are up to the former standard of excellence of the firms and companies issuing them, and we heartily thank the senders, reciprocating their good wishes for the new year.

The G. & C. Merriam Co., of Springfield, Mass., publishers of Webster's International Dictionary, now supply a need which is felt in most modern offices—that is, a dictionary, in handy form, and at a reasonable price, which gives the essence of the great International, with its definitions, synonyms, vocabularies of geographical, historical and proper names, tables of abbreviations, arbitrary signs, dictionary of mythology, etc. One of the special features of these appendixes is a very complete glossary of Scottish words and phrases, which will be generally appreciated in Canada. There is also a rhyming dictionary, and the definitions in the body of the book are elucidated by over 1,100 illustrations. The type is clear, the binding is unusually strong, and while, as its name, "Webster's Collegiate Dictionary," implies, it is specially adapted to the use of colleges and students, it is even better suited as a work for office reference. Although containing 1,016 pages, the work is not too bulky for convenient use, and we can endorse in the strongest terms the unqualified praise the new work has received from the highest educational authorities. It is published in three different bindings, cloth, sheep and half Morocco, with thumb indexes.

NEW CATALOGUES.

Interior Conduit is the name of No. 75 in the Sprague Electric Companies series of catalogues. These catalogues are, as we have said before, triumphs of the printers' art, and contain most valuable information for the electrician and the intending purchaser of electrical supplies.

The Smart-Eby Machine Co., Ltd., Hamilton, is sending out an attractive catalogue illustrating the "Webster" horizontal engine for gas, gasoline, or natural gas.

Innumerable illustrations enhance the interest of Steel Portland Cement, an artistic pamphlet sent out by the Illinois Steel Co., Chicago, to introduce its cement.

Industrial Notes.

Windsor Mills, Que., has voted $25,000 for a waterworks system.

A $10,000 Roman Catholic church will be built in Dublin, Perth county, Ont.

Meaford, Ont., voted a bonus of $56,000 to the G.T.R. and the proposed elevator.

The cheese factory at Bobcaygeon, Ont., will be changed into a butter factory.

Windsor, Que., is agitating for a waterworks system and an electric light plant.

An elevator to cost about $250,000, will be built in Quebec by the Great Northern Railway Co.

Lindsay, Ont., carried a by-law to buy the waterworks system from the company now operating it.

The Lamont Glass Works at Trenton, N.S., are to be put in operation by the Montreal Glass Co.

The sewage system in Pembroke, Ont., has been completed by the contractors, Russell & Fortin.

John Coughlan & Co., Victoria, B.C., have the contract for an hotel at New Westminster to cost $10,000.

The News-Record notes that Oelschlager Bros. are increasing their elevator building plant in Berlin, Ont.

The Cartwright, Man., Farmers' Elevator Company has been incorporated. The capital stock is $4,000.

R. B. Hanson, of Bocabec, N.B., proposes building a sawmill at the mouth of the Magaguadavic river.

Sarnia, Ont., will spend $25,000 on a trunk sewer, and $7,000 on waterworks in the present year.

St. Hyacinthe is to have a new shoe factory; the proprietors of it are A. Many, J. B. Hurteau and L. Baron.

J. Lawrence & Sons, Sarnia, Ont., have, it is said, made arrangements to erect a sawmill at Watford, Ont.

The Sutherland-Innis Cooperage Co. will build a stave, heading and hoop mill at Forest, Ont., this winter.

The Standard Chemical Company, of Toronto, is authorized to increase its capital from $80,000 to $450,000.

The Laprairie Brick Co., Montreal, has been incorporated with a capital stock of $150,000, to manufacture brick, etc.

Tottenham, Ont., has granted a loan of $15,000 to a Montreal man, who proposes to start a furniture factory there.

It is said that W. Chaplin, St. Catharines, will put up a veneer mill at Mansonville, Que., where he now has a handle factory.

A branch of the International Association of Machinists has been formed in Carleton Place, Ont., with Thos. Fraser as president.

The company proposing to make cement at Lake Medad, East Flamboro, Ont., are asking a bonus of $8,000, and speak of employing 75 hands.

The town of Durham, Ont., is asking legislative sanction for a loan of $10,000 to aid the Durham Furniture Co. in establishing a factory there.

It is said that C. H. Peters' Sons, whose tannery was recently burned at St. John, N.B., will establish their industry at Fredericton or in its suburbs.

The proposed sewage system for Bridgetown, N.S., has been postponed owing to the failure of the electors to come to an agreement. The voting resulted in a tie.

The Dodge Mnfg. Co., of Toronto, Ltd., has the contract for the shafting and hangers required for the large works of the Dominion Iron and Steel Co., Sydney, C.B.

The Acton Leather and Shoe Co., Ltd., has now completed the erection of its new tannery and factory at Actonvale, Que., and has begun operations in both places.

Arrangements are now being completed for the formation of a pork packing company in Simcoe, Ont. It will be the Simcoe Pork Packing Company, Ltd.; the proposed capital stock is $200,000.

The executive committee of the Brotherhood of Locomotive Engineers has decided to select a site in Cleveland for the permanent home of the Brotherhood. The land and building will cost $300,000.

C. Krug, W. Krug, J. Krug, C. Krug and H. Ankerman, Chesley, Ont., have been incorporated as the Chesley Rake and Novelty Co., Ltd. The capital is $20,000; chief place of business, Chesley, Ont.

Oshawa, Ont., will lend $50,000 without interest to the McLaughlin Carriage Co., in order to secure the firm's rebuilding its works, recently burned down. A three-story building, 700 x 50 feet, will be put up.

The Tracadie Lumber Company, whose mills are at Tracadie, in Gloucester county, N.B., is about to build a box factory to manufacture box shooks for the British market. The resident manager is B. H. Foster.

The works of the I. Matheson Co., New Glasgow, N.S., are being kept very busy on orders from the Dominion Iron and Steel Co., and in making up a large amount of mining machinery for the iron mines at Belle Isle, Nfld.

The Orangedale Brick and Trading Company, composed of Halifax men, are starting a large brick yard at Orangedale, C.B. They will manufacture with machinery on a large scale. Brick-making will commence in the early spring.

The municipality of St. Henri, Montreal, has decided to grant no more bonuses. This was their reply to an enquiry from the Phoenix Bridge & Iron Co., asking if a bonus would be granted in the event of the company's works being removed to St. Henri.

E. M. McDougall, Agnes H. McDougall, Jessie E. McDougall, spinsters; F. C. Henshaw, Montreal; Linda B. McDougall, Cobourg, Ont., and Robert Cowans, are being incorporated as the John McDougall Caledonian Iron Works Co., Ltd., Montreal.

T. Meyers, Bastard, Ont.; L. S. Lewis, J. N. Knowlton, Newboro, Ont., and L. H. Kerr, J. B. Pinkerton, South Crosby, Ont., have been incorporated as the Ontario Milling and Manufacturing Co., Ltd.; chief place of business, Deloraine, Man.; capital, $40,000.

Failure to pay the promised bonus of $1,000 a year has caused the courts to give the J. D. King Boot and Shoe Co. a judgment against the town of Levis, Que., and under it the J. D. King Co. has seized the property of the municipality, including fire engines, etc.

L. W. Manchie, Newmarket, Pa., and W. G. Foster, of Foster & Co., Utica, N.Y., have leased part of the Toronto Carpet Co.'s buildings on Esplanade street, Toronto, from the Atlantic Refining Co., and will make iron beds, etc., under the name of the Toronto Bedding Co.

J. A. C. Madore, M.P.; Geo. Janin, C.E.; A. Stuart, C.E.; J. B. Lapointe and I. L. Lafleur, Montreal, are being incorporated as the La Compagnie d'Assainissement et d'Utilisation des eaux d'egout, to run a sewage farm; proposed capital, $50,000; chief place of business, Montreal.

J. Penman and J. B. Henderson, Paris, Ont.; T. Littlehales, Syracuse, N.Y.; W. D. Long and H. Long, Hamilton, have been incorporated as the Penman-Littlehales Chemical Co., of Hamilton, Ltd., to manufacture chemicals from gas tar; chief place of business, Hamilton, Ont.; capital, $50,000.

An engineer by the name of Lodian claims to have determined that steel rails begin to expand after a temperature of —50° F. is reached. We would be glad to hear experiences of C.P.R engineers along the north shore, where it is cool also, if not so cool as in Siberia, where M. Lodian's observations were made.

The Ronald Fire Engine Works, Brussels, Ont., is sending out a circular, which contains some testimonials in the form of telegrams sent in answer to the enquiries of the mayor of St. John's, Que., by the fire chiefs of various towns where Ronald engines were in use. These telegrams are highly complimentary.

Canada Wood Specialty Co., Ltd., Orillia, Ont., organized by J. B. Tudhope, Wm. Tudhope, A. McPherson, J. H. Lavallee, Wm. Thomson and Geo. Thomson, is trying to secure from the town the following as a bonus: "Free light for office and factory purposes, water for drinking, 50-h.p. of electric energy, and exemption from taxation."

G. W. Grant and A. Dods, Toronto, Ont.; T. H. Hamilton, J. M. White, J. W. Gray, M.D., W. H. Hill and W. Irwin, Peterborough, Ont., have been incorporated as the Grant-Hamilton Oil Company, of Toronto, Ltd.; to manufacture and sell oils and petroleum products, varnishes, soaps and engineers' supplies; chief place of business, Toronto; capital, $40,000.

Instructions have been issued by the Customs Department at Ottawa cancelling instructions of July 1st, 1897, respecting duty on round steel in bars. The standard is advanced from 1-inch in diameter to 1½ inches, and on round steel in bars (polished) one and one-half inch in diameter and larger; the duty will be 30 per cent. ad valorem, instead of 35 per cent., as formerly.

The Dodge Mnfg. Co., of Toronto, Ltd., has enjoyed a most successful year's trade, the company's business being greater by 50 per cent. than for any previous year in its history. The Dodge Company makes a specialty of shafting, hangers and pulleys, as well as friction clutch pulleys and rope driving, and few large factories, it states, have been equipped recently which were not supplied in this line by the Dodge Co.

The United Correspondence Schools of New York city have a course of study in Mechanical Engineering especially designed to meet the needs of machinists, inventors, draughtsmen, tool-makers, machine shop laborers, pattern makers, boiler and engine builders, shop foremen, moulders and foundrymen, blacksmiths, engineers, builders and salesmen of machinery and others.

Chew Bros., Midland, Ont., have sold their sawmill property to Turner Bros., who will enlarge it. In the meantime Chew Bros. are at work upon another site in the east part of the town, where they will erect a new mill with all modern equipment. The Playfair Co. also has purchased a site, upon which it is about to erect a large timber mill. It is expected that these two mills will employ about two hundred men.—Orillia Packet.

Some years ago a local company was floated in Perth, Ont., and a bonus was secured. The Perth Courier recently published the following paragraph, which might well have been part of the obituary column: "Pending the re-opening of the Facer Car Wheel factory, the C.P.R. has taken up the switch and the rail connection, and removed the semaphore. These can be replaced when the company begins operations."

The acetylene gas plant in the Fort Steele, B.C., postoffice exploded recently, severely injuring postmaster Cann and his assistant, H. McVittie. The accident occurred through making an examination by candle light. This is an example of gross carelessness, and the accident cannot be attributed to the fact of its being acetylene gas; coal gas would explode under similar conditions.

M. J. Dodge, New York; A. R. Creelman, Q.C., and J. J. McNeil, Toronto; W. J. Sheppard, Waubashene; W. Irwin, Peterborough; A. McLeod, Bracebridge; T. H. Sheppard, G. McCormick, Orillia; J. Playfair, Midland; C. A. McCool, Ottawa, and W. D. Lummis, Spragge, Ont., have been incorporated as the Spanish River Pulp and Paper Company, Ltd., with a capital of $1,500,000.

The Laurentide Pulp Company, Ltd., has applied to the Quebec Government for an Act to amend the Act incorporating the village of Grand Mere, Que., in order to enable the officer of the said company appointed for that purpose by its board of directors, to vote in the name of the said company on all by-laws, which by-laws must be submitted to the proprietors of real estate in this village, and also to vote at the election of municipal councillors.

The Welland Press some little time ago made these sage observations about a bonus scheme: "The Hamilton iron works projectors ask a cash bonus of $25,000. Port Colborne can have them. Welland don't want them at that price; $25,000 to start other people in business is a little too thin. If they got it, they wouldn't be like other bonus-hunters if they didn't demand another $25,000 in a few years as the price for not moving away."

The Yale and Columbia Lumber Co., Ltd., which is the partial consummation of the effort to consolidate all the lumber mills of Yale and Kootenay, B.C., has been organized and includes the Genelle and Pupore mills, Nakusp, Robson and the Arrow Lakes, also the Blue mills of Rossland and Ymir, and Fisher's mills at Eholt, Phoenix and Rock Creek. The company is to be incorporated for half a million. The company has timber reserves estimated at 500,000,000 feet. Its head office will be at Greenwood, B.C.

The Gutta Percha and Rubber Manufacturing Company, of Toronto, recently finished an enormous driving belt. It was of rubber, and measured 3,520 feet in length. Its weight was nine tons. This mammoth belt was made for the grain elevator of the Intercolonial Railway at St. John, N.B., and is now in use there. Another immense main drive belt, 58 inches wide and 338 feet long, with a weight of two and one half tons, was recently completed for one of the Canadian Pacific Railway elevators at Fort William by the same company.

While British trade with Canada has largely increased, the Dominion drives a thriving commerce with the United States. The annual report of the Secretary of the United States Treasury shows Canada to rank fourth among the nations in respect of the bulk of the business done with the Republic. The total trade with the United States for the past twelve months was as follows: Great Britain, $630,260,922; Germany, $230,097,050; France, $122,742,955; Canada, $121,181,910; Netherlands, $93,763,618; Brazil $70,114,783. No other nation reached the forty million dollar mark.

Various Ontario gas companies were represented recently at a meeting in Toronto at the Walker House. The high price of materials for making gas was discussed. Within the past two years gas oil has gone up 50 per cent. in price, and the duty of 2½ per cent. is said to be prohibitive. A deputation will shortly wait upon the Dominion Government in this connection. The gas men declare it is hard to make both ends meet, which is a statement whose absurdity is so great as to cause laughter to all except those who are buyers of gas from these companies. A gas company which is not earning ten per cent. dividends is doing a poor business.

J. W. Tyrrell, C.E., Hamilton, Ont., has been chosen by the Dominion Government to explore the Keewatin district, to the east of Great Slave Lake in the Northwest Territories, as far as Chesterfield inlet. A few years ago Mr. Tyrrell explored the region north from Lake Athabasca to Chesterfield inlet, and the result of his labors was of great value to the Government. As far back as 1834 Sir George Back explored to the east end of the Great Slave lake, but stopped there on his march eastward. Mr. Tyrrell was expected to leave Edmonton about January 1, and expects to reach Fort Resolution late in March. He will be accompanied by the Rev. Archdeacon Lofthouse, of Fort Churchill. He will be away about ten months.

During the academic year 1898-99 Sir William C. McDonald has contributed to McGill University, Montreal, $7,650 to make up deficiencies in the income of the Faculty of Applied Science, and in addition to very many other generous gifts has given $30,000 to supplement the equipment of the electrical engineering laboratories; $55,000 to endow the department of mining and metallurgy, $90,000 additional endowment for the chemistry and mining building, $10,000 additional endowment for the chair of electrical engineering, $50,000 to found a chair of history associated with the name of the late Dr. William Kingsford, and has strengthened the auxiliary endowment fund, which he established in 1897, by the sum of $51,250, and a further sum of $62,500 to found and endow a "Dawson chair of geology."

Cities and towns which offer bonuses and other inducements to manufacturing concerns to locate within their borders have encouraged an evil which may recoil adversely on themselves, says the Montreal Daily Witness in a recent editorial paragraph. An instance of this sort of thing is given in the case of the Kingston Locomotive Works. It appears that the company has been offered a bonus of $75,000 to remove its plant to a town in another province, but it is said they will be content to remain in Kingston if that city will grant them the same amount. This opens a new way by which manufacturing companies may recruit their finances and gain other advantages. Any concern might manage so as to get an offer from another municipality than that in which it is situated to transfer its works for a bonus, and use the offer to compel its own town to pay a like amount under pain of removal. This is a dangerous game for municipalities to play with each other.

The announcement is made that the National Cycle and Automobile Company has decided to establish its plant in Hamilton, Ont. The company has leased temporary quarters in the old Wanzer building. James Dodge, of the Evans and Dodge Bicycle Works, Windsor, will superintend the installing of the plant in the factory. It is altogether likely that with the removal of the E. and D. bicycle works from Windsor, Ont., the Canadian Typograph Company's works, which has the same management, will also be removed there. The understanding arrived at with the company was that Hamilton men were to provide the money for the erection of the necessary factory buildings, which, with the site, were estimated to cost about $20,000. In addition to this, a bonus of $5,000 was to be raised by private subscription. In return the company agreed to provide employment for at least 300 men all the year round. The company speaks of doing a large export business.

The following were among the enquiries relating to Canadian trade received at the Canadian Government office in London recently: Walnut boards of good quality, and wooden screws, are required in considerable quantities by a London firm. The names of Canadian makers of sporting ammunition, such as .22 calibre rim fire ball cartridges used for shooting gallery purposes, and any other cartridges for small bore sporting rifle, are enquired for. Enquiry is made for firms in Canada who would supply cheap wood mantel pieces to be sent

over in a knock down condition. A large firm of manufacturers of enamelled, tinned, galvanized and japanned hollow-ware, sauce-pans, buckets, pails, etc., desire to do business with Canadian houses, and ask to be placed in communication with buyers. A Scotch firm largely interested in the export of Canadian goods, such as furniture, woodenware, hardware, provisions etc., desire to extend their business in the export of Canadian goods to British India and the Cape, and are therefore open to hear from houses who may wish for their co-operation.

Plans submitted for protection to the piers of the Ottawa and New York Railway bridge, in course of construction over the St. Lawrence River at Cornwall, Ont., have been accepted by the Department of Railways. In the old structure the bottom was solid enough to hold the weight, but owing to the depth of water and the rapid current it was deemed advisable to reinforce the substructure. According to the plans submitted it is proposed to rip-rap the pier nearest the island with heavy stone blocks of half a ton or a ton each, piling up sufficient of them to protect the concrete from ice action. To secure the pier near the Cornwall canal an annular steel caisson will be built and sunk around the present crib several feet below the bottom of the river. This will be filled with concrete, and the new and old material knit together as far as may be to form one solid mass, the whole being tied with cables embedded in concrete. The pier at the canal bank appears to have been built on soft soil, being already a couple of inches at least out of plumb, and will be taken down and rebuilt, the foundation being made perfectly secure and means taken to prevent scouring.

Personal.

J. W. Curtis, electrician for the Canada Paper Co., Windsor Mills, Que., is seriously ill.

Frank Duhamel, an engineer, and a native of New Brunswick, died in Vancouver, B.C., on November 15th, of consumption.

A. R. McVicar, Wardsville, Ont., has gone to Mexico, to superintend the construction of 100 miles of railway, for which his brother has the contract.

B. Laird, of the Robb Engineering Co., Amherst, N.S., is now in Cuba, installing some engines supplied by this company for street railway power purposes.

Maurice Bucke, mining engineer, was accidentally killed at Bear Gulch mines, near Jardine, Montana, last month. He was 31 years of age, and was a son of Dr. Bucke, of London, Ont.

William Mason, bursar and lecturer of the School of Mines, Kingston, Ont., died December 7th from acute tuberculosis. Deceased was a Scotchman, 56 years of age, and was with the British army in India.

P. L. Nasmith, who recently left the employ of the Dominion Coal Co., at Glace Bay, C.B., was presented by the employees of the company with a gold watch and chain, and Mrs. Nasmith with a silver tea service. H. Donkin, resident manager, made the presentation.

E. B. Wingate, city engineer, Hamilton, Ont., was naturalized as a Canadian citizen recently. At the time of his appointment, Mr. Wingate was a citizen of the United States.

Six miners at Sydney Mines, C.B., Z. Burchell, J. Edwards, D. Edwards, A. McDonald, R. Dixon, and N. McKenzie, fell a distance of 350 feet, and were badly crushed, a short time ago.

Francis Mill, C.E., died rather suddenly on 25th November last, aged 30 years, at the residence of his father, James Mill, J.P., Glenburnie, Maria, P.Q., from inflammation of the lungs. Mr. Mill had been in feeble health for the last four or five years. He was educated at Claremont College, Wallasey, England, and at the School of Practical Science, Toronto, and then became assistant engineer under Willis Chipman, Toronto, on the waterworks at Brockville, Ont. His friends will regret to learn of his death.

Baron Adolphe von Hugel died at the Royal Victoria Hospital, Montreal, December 20th, he having entered that institution on December 15th, suffering from an attack of paralysis. Upwards of thirty-five years ago Baron von Hugel came to Canada from Germany, and soon afterward became identified with the Midland Railway, of which he was president. At that time he lived in Port Hope, and served as Mayor of that municipality. During this time he built the Midland Railway, which eventually fell into the hands of Geo. A. Cox, and was sold by him to the Grand Trunk Railway, and became a part of that system.

James S. Taylor and Jos. Taylor, brothers of John M. Taylor, secretary-treasurer of the Dominion Radiator Co., Toronto, are now troopers in C Company, Bethune's Mounted Infantry, in South Africa. When the war broke out they were firmly established with head office in Johannesburg, and branches at Durban and Pretoria, having large mercantile interests there, holding large stocks of Canadian goods in South Africa, notably the Dominion Radiator Company, the James Morrison Brass Company, the Steel-Clad Bath Co., of Toronto, and the Pedlar Roofing Company, of Oshawa. They were jointly contractors for the Johannesburg city hospital, and in October were offered protection if they would remain and look after the hospital building in case of necessity. Later, they were ordered to leave Johannesburg.

T. H. Browne, engineer in charge of the Havana Street Railway, died last month in Cuba, of yellow fever. Captain Browne was born in Montreal in 1870. He entered the Royal Military College, Kingston, from Lincoln College, Sorel. Graduating with honors in the electrical and mechanical branches of the R.M.C., he took up a position on the construction work of the Montreal and Ottawa Railway, a year later being appointed architect for the Dominion Government in the province of Quebec, having charge of all work on Government buildings, rifle ranges, etc. Taking up his residence in Montreal, he took a commission in the Royal Scots, attaining the rank of captain, and retiring retaining rank. In 1897, he left Montreal to take a position on the staff of the Boston Street Railway, and in December, 1898, resigned that post to join the engineering staff of the Metropolitan Street Railway, New York. He resigned that place in September last to take the appointment of engineer of the new street railway in Havana, Cuba.

Walter Shanly, C.E., ex-M.P., and one of the best known engineers in America, died December 17th at the St. Lawrence Hall, Montreal, where he made his home for a great number of years. Although 82 years of age, Mr. Shanly was able to be about up to a few days ago, when he became afflicted with extreme weakness, and, although his splendid intellect was bright to the end, he kept getting weaker, until he passed peacefully away. He was the fifth son of the late James Shanly, a member of the Irish bar, who came to Canada in 1836, and settled in Middlesex County, Ont. Deceased was born at "The Abbey," Queen's County, Ireland, October 11th, 1819; was educated by private tuition, and adopted the profession of civil engineer. In his younger days he was employed by the Canadian Government on the Beauharnois and Welland canals; was engaged on railways in the United States, and later, 1851—53, was engineer of the Ottawa and Prescott Railway. Between 1851 and 1862 he was successively engineer of the Western Division of the Grand Trunk, engineer of the Ottawa and French river navigation surveys, and general manager of the Grand Trunk Railway. His most important railway work was the construction of the Hoosac Mountain tunnel, in Massachusetts, in which he was associated with his brother, the late Frank Shanly, C.E. He was widely known as a consulting engineer. He sat in the old Parliament of Canada from 1863 till Confederation, and after the union sat in the first, fifth and sixth Parliaments. He gave an unyielding support to the late Sir John Macdonald, and was the contemporary, colleague and friend of Cartier, Galt, D'Arcy McGee and other brilliant men of the time. In 1864 Mr. Shanly was a delegate to the Detroit Trade Convention, along with the late Hon. Joseph Howe, Mr. John Young, and other representative men of the British provinces. He was for some years president of the Mechanics' Bank. The funeral took place in London, Ont.

Electric Flashes.

Sarnia, Ont., is granting a 30 years' franchise to the street railway.

L. Smith, Blenheim, Ont., proposes to put in an electric light plant at Little Current, Ont.

In Pembroke, Ont., a by-law for the purchase of the electric light plant was carried by over 200 majority.

The corporation of Picton, Ont., has awarded its meter and supply orders to the Canadian General Electric Co.

W. H. Meldrum purchased the entire plant of the Paris Electric Light Co., and took possession on Dec. 12.

H. Corby, distiller, Belleville, Ont., has placed an order with the Royal Electric Co. for a 100-light direct current generator.

In Woodstock, Ont., a by-law was voted on, January 1st, for the purchase of the electric lighting plant, which was carried. All night lighting was decided on.

The Cataract Power Company, Hamilton, Ont., is building a brick addition to the transformer station at Victoria avenue, Hamilton, which will cost $8,000.

Gilmour & Co., Trenton, Ont., has lately installed in their mills a 100-light D.C. generator from the Royal Electric Co.

The Cataract Power Co., Hamilton, Ont., will provide free electric lighting to the township of Barton in return for a right of way.

The McCarthy Brewing Co., of Prescott, Ont., is installing a lighting system in its brewery at Prescott, using the Canadian General Electric Co.'s apparatus.

The Granby Consolidated Mining and Smelting Co., Grand Forks, B.C., has installed a 50-light direct current generator of the Royal Electric Co.'s manufacture.

The Ogilvie Milling Co., of Winnipeg, Man., has bought from the Canadian General Electric Co. a 30-k.w. direct current generator of its standard multipolar type.

The Drayton, Ont., Electric Light Co. is refitting its station equipment, and has placed an order for a 30-k.w. "S.K.C." twophase machine with the Royal Electric Co., Montreal.

The Dominion Iron and Steel Co., Sydney, C.B., has added another 40-h.p. 250 volt motor to the order already given for electric plant. The Canadian General Electric Co., has the entire contract.

The American Alkali Co., of Sault Ste. Marie, has placed an order for the switchboard necessary for its electrolytic plant, with the Canadian General Electric Co., which company is supplying the generator.

The Faculty of Applied Science, McGill University, Montreal, has received from a United States citizen, resident in New York, $10,000, to found a research scholarship at McGill in electrical engineering.

The Toronto Carpet Co. has increased its order for electric plant, and is now installing a 55-k.w. generator in place of the 30-k.w. originally ordered. The Canadian General Electric Co. has the work in hand.

Bothwell, Ont., is increasing its plant by the installation of two 20 k.w. generators to replace those originally purchased. The order, as in the first case, has been placed with the Canadian General Electric Co.

F. J. Davidson, Windsor, N.S., and H. McC. Hart, Halifax, N.S., are interested in the proposed calcium carbide works at Windsor, N.S., for which local capital, amounting to $100,000, has been subscribed.

According to the report of the Inspector of Weights and Measures for the year ending June 30th, 1899, there were doing business in Canada, 276 companies or individuals, supplying electric light, having a total of 630,732 lamps.

The Dodge Mnfg. Co., of Toronto, Ltd., has just installed a complete jack shaft equipment, consisting of floor stands, heavy shafting, iron pulleys, friction clutch pulleys, belt tightener, etc., in the new municipal electric plant of the city of Winnipeg.

The Kingsville, Ont., Electric Light Co. is increasing the capacity of its incandescent plant by the addition of a 75-k.w. alternator, the order for which has been placed with the Royal Electric Co.

The Manhattan General Construction Co., Newark, N.J., has sold, through its Toronto office, a 35-lamp alternating current series arc lighting plant, including regulator, to the corporation of Campbellford, Ont.

J. M. Deagle, of Cataract, Ont., has ordered a complete electric light plant for the town of Erin, Ont., with the Royal Electric Co. The order includes a 30-k.w. alternator, and 300 light capacity in transformers.

The St. Francois Xavier College, Antigonish, N. S., has placed an order with the Canadian General Electric Co. for a storage battery plant, consisting of a fifty-five cell battery, and one M.P.-4-17½-k.w. direct current generator.

A large number of motors taken in exchange are advertised for sale by the Jones & Moore Co., under the heading of Electric Bargains. Many of those offer exceptional values, as they are of standard voltages and makers, and have been but slightly used.

The Toronto Rubber Shoe Mnfg. Co. has purchased a 35-lamp alternating current series arc lighting plant, including regulator, for its factory, and the street illumination in Port Dalhousie. The Manhattan General Construction Co. is furnishing the equipment.

The Toronto Rubber Shoe Co., of Port Dalhousie, Ont., is installing in its new factory a 150-k.w. "S.K.C." twophase generator with switchboard, and one 30-h.p., and one 7-h.p. "S.K.C." twophase induction motors. The entire factory will be lighted and operated by electricity.

The St. Thomas Gas and Electric Co. is increasing its lighting capacity, and in doing so has decided to change its lighting system from singlephase to twophase, having ordered from the Royal Electric Co. a 150-k.w. "S.K.C." twophase machine with marble switchboard and instruments.

The Toronto and Hamilton Electric Co., Hamilton, Ont., is now in its new shop, a two-story building, 60 x 100 feet, in which some new machinery is being installed to meet the requirements of the increasing business of the company. All the machinery in the works is electrically driven.

The Pittsburg Reduction Company has awarded a contract to the Westinghouse Electric and Manufacturing Company for 11 electric generators, to cost $150,000, for installation in the great new aluminum works it will erect early next spring at Shawenegan Falls, on the St. Maurice River, Quebec.

The Coaticook Electric Light and Power Co. is increasing its lighting plant by the installation of another 2,000-light alternator with switchboard. It is also catering for electric power, for which purpose it has bought a 100-k.w. 550 volt direct current generator with switchboard complete. Both the above machines are of the Canadian General Electric Co.'s standard make.

The Dominion Electric Heating and Supply Co., Ottawa, has been out of business for the past year, owing to a dispute between the inventor of the process and the directors of the company. The creditors have received nothing, but efforts are being made to sell the second process of the company, and if this is done a dividend may be paid.

The St. Thomas Gas and Electric Co. is making changes and additions to its plant to meet increasing demands. For arc lighting purposes it is installing a Brush arc dynamo, with capacity for 125 lamps, manufactured by the Canadian General Electric Co. This company has also been operating the St. Thomas Street Railway for some time past from its power house, using two 100 k.w. generators of the General Electric standard type.

Greenwood, B.C., is putting in a lighting plant. G. C. Hinton & Co., Vancouver and Victoria, B.C., have the contract which calls for one 150-k.w. 2,000 volt, twophase "S.K.C." inductor type generator of 3,000 light capacity, complete with all equipments; and all material, insulators and supplies, the generator, switchboard, etc., being of the very latest and most approved pattern. The plant will cost in the neighborhood of $20,000.

As the result of a conference between Dr. Hoepfner, of the Hoepfner Refining Company, Hamilton, Ont.; John Patterson, of the Cataract Power Company, and an expert from the Krupp Gun Works, in Germany, it has been decided to enlarge the refinery premises in Hamilton by four times its present dimensions. The plant as it now stands consists of a main building, 236 x 55 feet, and three smaller buildings, and as soon as these are in operation the enlargement will be started, and the works when completed will cover six acres of land.

The Orangeville Electric Light and Power Co. is improving and extending its plant to meet a constantly increasing business, and a demand for an improved and economical street lighting circuit. For its incandescent requirement it has ordered another standard 60-k.w. alternator, with a complete new marble panel board for both machines. For the street lighting the present open arc direct current plant will be abandoned and in place will be installed a constant current alternating system. This will consist of a 50-light series transformer with switchboard for same, together with 30 improved constant current lamps for operation from the same. This company has recently discarded the old 52 volt switchboard transformer system, substituting therefor large size type "H" transformers, feeding into a complete system of 3-wire secondary mains designed in accordance with modern practice. The single phase system will be adhered to. The Canadian General Electric Co. has the contract.

The Montreal Cotton Co., Valleyfield, Que., is pushing the extension to its new power house, and expect that by May 1st next, it will be completed, and the new 1,200-k.w. generator in operation. An interesting feature of this installation, which will be the largest industrial electric plant in the world, will be the switchboard arrangement. This will consist of a series of blue vermouth marble panels, 36 inches wide by 88 inches high, upon which will be mounted the necessary switches for controlling the motor circuits, and all instruments for controlling the generators and exciters. There will be used for present equipment twelve feeder panels and six generator panels. The entire board, as covered by present orders, will be 54 feet long, and when completed will present an imposing appearance, and will meet all requirements necessitated by the peculiar condition under which this plant operates, and the entire work will no doubt reflect credit upon the Canadian General Electric Co., to whom it has been awarded.

A good evidence of the progress of Montreal as an electrical centre may be afforded by a visit to the new premises of John Forman, 708 and 710 Craig street. To accommodate his increasing business in electrical supplies, Mr. Forman has appropriated the whole of one of the substantial new buildings erected in Craig street in 1899. The new premises are four stories high, beside basement, and are admirably lighted and fitted up. The different departments are well laid out, both for convenience for shipment and for attaining the best effect in the show of goods. The basement is devoted to heavy goods, such as cables, heavy wires, conduits, insulators, etc., and is lighted by electric lights with double glass reflectors. A goods and passenger elevator connects the basement with the other flats. On the ground floor are the general offices, which are handsomely designed, and at the rear are supplies of various kinds. The first floor above this contains Mr. Forman's private office, and a new laboratory equipped with various instruments for testing incandescent lamps, etc., these instruments costing over $1,000. A noteworthy feature of this laboratory will be, that any person, no matter whether a customer of the firm or not, may have the benefit of these instruments, and no charge whatever will be made for testing lamps—beyond of course the cost of carriage from points outside the city. The privileges of this department will no doubt be appreciated by users of electricity. Portions of these two flats will be devoted to the display of electrical fixtures and supplies, and the two stories above these will be devoted to manufacturing. Mr. Forman has purchased the plant of the Canadian Bryant Electric Co., and will carry on the manufacture of all lines of supplies made by that company, including branch-blocks, mains, cut-outs, rosettes, switches, sockets, etc. The trade mark "Imperial" has been registered by Mr. Forman, and this striking emblem, which appears in his advertisement on another page, is sure to be a familiar one in the electrical field in future.

The McLachlan Electric and Gasoline Motor Co., Ltd., Toronto, has recently supplied the following: Duncan & McLennan, Campbelltown, N.B., two 50-light dynamos and one 3-h.p. gasoline engine; Hill & Rutherford, Victoria Glass Works, Toronto, one 15 and one 8-h.p. motor; Rodden Bros., Toronto, three 12-h.p. motors; Imperial Woolen Mills Co., Streetsville, 200-light, installation complete; Leitch & Turnbull, Hamilton, five 6-h.p. motors; Purdy, Mansell & Co., Toronto, two 6-h.p. motors; Douglas Ford, Toronto, one 8-h.p. motor; White, Allan Mnfg. Co., Toronto, two 3½-h.p. motors; T. Eaton & Co., Toronto, one 5-h.p. motor; E. B. Corlett, Toronto, one 2-h.p. motor; J. B. Kleinert Rubber Co., Toronto, one 3-h.p. motor; McKenzie, Snyder Co., Toronto, one 12-h.p. motor; Temple Building, Toronto, one 6-h.p. motor; Thompson Bros., Toronto, one 4-h.p. motor; A. E. Long, Toronto, one 2-h.p. motor; A. R. Williams & Co., Toronto, one 10-h.p. motor; O'Leary & Robillard, Ottawa, one 8 and one 15-h.p. motor; W. R. Robertson, Brantford, one 1-h.p. motor; Continental Costume Co., Toronto, one 6-h.p. motor; Capp & Co., Toronto, one 3-h.p. motor; H. W. Petrie, Toronto, one 2 and one 8-h.p. motor; Gold Medal Mnfg. Co., Toronto, one 25-light dynamo, full installation; Walter Dean, Toronto, one 6-h.p. motor; Mathew Bros., Toronto, one 30-light dynamo, full installation; Wm. Meek, Kingston, one 2-h.p. motor; John Henry & Sons, Ottawa, one 8-h.p. motor; Murray Printing Co., Toronto, one 12-h.p. motor; H. W. Petrie, Toronto, one 60-light dynamo and one 8-h.p. motor; Tarbox Bros., Toronto, one 3-h.p. motor; Mrs. Frero, Toronto, one ½-h.p. motor; Meteorological Office, Toronto, one 1½-h.p. motor; Dancyger Safety Pin Ticket Co., Toronto, one 3-h.p. motor; G. T. Pendrith & Co., Toronto, one 2-h.p. motor; Meyer & Shapro, Toronto, one 2-h.p. motor; Jas. Goldie, Guelph, one 5-h.p. motor.

Railway Matters.

The Grand Valley Railway, which proposes to build lines from Goderich to Port Dover and Stratford, Ont., has given notice of application for incorporation.

In Lindsay, Ont., a by-law was carried to grant a bonus of $25,000 to the proposed Lindsay, Bobcaygeon & Pontypool Railway. The township of Verulam voted $14,000, and the town of Bobcaygeon, $11,000.

The Pontiac, Pacific Junction Railway Company, will apply next session for right to construct a railway from Quyon or Shawville, Que., to Pembroke, Ont., and branches not exceeding thirty miles.

Logan, Jenks & Outhetо, of Amherst, N.S., give notice of application for the incorporation of a company to build a line of railway from Pyramid Harbor by the Dalton trail to Fort Selkirk, and on to Dawson.

Prof. C. H. McLeod, C.E., and a party of fourth year students have surveyed a cut-off line at Hamilton, Ont., to relieve traffic on the "Y" for the use of the through traffic, near Waterdown station. The grades have been much improved.

The Canadian Pacific Railway will construct or acquire a railway from Morden on its Pembina Mountain branch, to Miami, and to Carman, Man.; and also a railway from a point between Hartney and Souris on the company's Souris branch, to a point between Boissevain and Ninga on the Manitoba and Southwestern Colonization Railway.

Application will be made for a charter to build a railway from the mouth of the French River, in the Parry Sound district, through the districts of Parry Sound and Nipissing and the county of Renfrew, Ontario, to Pembroke, thence through the county of Renfrew to a point at or near the village of Portage du Fort, Que., with power to erect bridges across the Ottawa River, etc.

A serious landslide occurred at Kaslo, B.C., last month. A strip of water front eighty to a hundred feet wide, and 250 feet long, at the Canadian Pacific Railway landing, sank. All the piling which the C.P.R. has been driving for the past season, on which to build its wharves, and which would have been completed in a short time, dropped out of sight without a moment's

notice. The two wharves were being built side by side, that of the C.P.R. having about 100 feet of work done upon it, while the Kaslo and Slocan Company's was about completed. The last pile was being driven when the collapse occurred.

M. H. Fitzpatrick has in conjunction with his brother, Hugh Fitzpatrick, Pictou, N.S., about completed the Midland Railway of Nova Scotia, the promoters of the line being W. Strachan, D. L. Lockerby, Peter Lyall, W. D. Reid and others of Montreal. If it were not for the heavy bridge over the Shubenacadie River, fifteen miles west of Truro, N.S., passenger trains could be run over most of the line, but the delay at the bridge will probably delay the opening of this railway till the early autumn of 1900. The New York Engineering Company has built the two abutments and two piers of this bridge, leaving three piers to be constructed next summer.

F. H. McGuigan, general superintendent of the Grand Trunk Railway, recently said that the G.T.R. has laid, during 1899, 13 miles of double track and has the whole line doubled between Montreal and Hamilton, except 46 miles, from Port Union to Port Hope. If business is good, this link will be closed up in the near future. The double track from Hamilton to Niagara Falls is also laid out, and the work will be proceeded with next season. It has likewise been decided to double the line from Port Huron to Chicago in the near future. No less than 315 miles have been relaid this year, with new 80-lb. steel rails, while 285 miles of these rails, replaced by the 80-lbs., have been laid down on the branch lines, the latter being from 72 to 79 lbs., and replacing in turn rails of from 56 to 60 lbs. So it will be seen that no less than 600 miles of the company's lines have been greatly improved. From Portland to Chicago there are now laid 720 miles of these standard 80-lb. rails, while the steel in the balance of the main line between those points average from 72 to 79 lbs. They have laid, during 1899, 1,826,857 ties, 1,344,374 being cedar, and purchased in Canada. The company put down last year 321 miles of gravel and 50 miles of cinder ballast, 123 miles of new fence and 63 miles of yards and sidings.

Marine News.

Over 40,000 tons of coal have been brought to Sarnia, Ont., this fall by vessels.

Water was turned into the Chicago Drainage Canal at 9 o'clock, January 2nd.

The St. John Sulphite Fibre Co. has bought barges to use in bringing pulp up from the mill at Mispec to St. John, N.B.

At a meeting of the shareholders of the Sydneys' Ferry Co., Ltd., held in December it was decided to buy two new steamers for their ferry business next season.

H. W. Kennedy, M. Brown, W. Ross, and G. C. Frisbie, Rat Portage, Ont., and A. R. Bartlet, Windsor, Ont., have been incorporated as the Commercial Dock Company of Rat Portage, Ltd.; capital, $10,000.

Steamer "J. L. Nelson," built by W. H. Butler, of Yarmouth, for T. F. Smith & Co., of Newdy Quody, Halifax county, has been successfully launched. The new steamer is 68 feet long by 13½ feet beam and 7 feet deep. She is fitted with 7 x 14 x 12 compound surface condensing engine and a boiler 9 x 4 x 25 feet, carrying a working pressure of 140 pounds.

The United States project to place a dam across the mouth of Niagara River to permanently raise the level of Lake Erie some three feet is assuming a serious and tangible shape. It has been recommended by the Deep Waterways Commission, and Representative Corliss, of Detroit, is preparing a bill to bring before the United States Congress making an appropriation for construction. Of course the co-operation of the Canadian Government will have to be secured before the scheme can be gone on with.

—The Pratt & Letchworth Co., Buffalo, have bought the G.T.R. car works at Brantford, Ont., and will produce malleable iron for the Canadian trade.

FIRES OF THE MONTH.

Dec. 7th. The McLaughlin Carriage Co.'s works, Oshawa, Ont.——Dec. 10th. The Exeter, Ont., electric light station.——Dec. 11th. H. Kreig's woodworking shop, Hespeler, Ont.; engine house destroyed.——Dec. 12th. Owen Sound Iron Works pattern shop.——Dec. 14th. Machine shop of the Shore Line Railway, St. George, N.S.——Dec. 14th. Steamer belonging to G. F. Marsh, tug belonging to Shaw, Cassels & Co., at Huntsville, Ont.; loss, $6,000——Dec. 18th. Shearer's lumber mills, Point St. Charles, Montreal; loss, $20,000.——Dec. 20th. Charite L. Patterson Mnfg. Co., makers of tar paper, Halifax, N.S; loss, $5,000.——Jan. 3rd. H. C. Rees' stave mill, Woodslee, Ont.; loss, $3,000.

—Inglis & Sons, engine and boiler makers, Toronto, are about to build refrigerating machinery on a large scale.

—F. Moore, of the Jones & Moore Electric Co., Ltd., Toronto, has been for some weeks suffering from a severe attack of typhoid fever.

—Henry Aylmer, Melbourne, Que., intends to establish a large sash and door factory and sawmill. Electric power will be used, it is said.

—Sproatt & Rolph, architects, Toronto, have prepared plans for a glycerine refining plant to be installed in connection with Lever Bros., soap factory, Toronto.

—C.A.S.E. Toronto No. 1, at its regular meeting, January 3rd, elected A. M. Wickens and Chas. Moseley as representatives of the C.A.S.E. on the Board of the Technical School. At the open meeting on January 17th, J. Hunter will read an essay on "Refrigeration."

—The Hamilton Bridge Works Company, Ltd., has issued the following circular: "We beg to announce that W. H. Law has been appointed chief engineer and manager of this company. H. Szlapka will remain with the company, attached to the engineering staff." Mr. Law, who was formerly general manager of the Central Engineering Co., of Peterboro, has been heartily congratulated by his friends from many quarters on this return to his own special field.

FOR SALE

A good Water Power, 500 horse, situated one-half mile from railway, every facility for making siding to power. Address

J. D. THEUNISSON, Cookshire, Que.

Bridge Tenders Wanted.

Sealed Tenders (marked tenders for bridge) for the superstructure of a steel bridge over the South Nation River at Lemieux, on the boundary line between Prescott and Russell, Ont., will be received by the undersigned up to the 20th January next, inclusive (1900).

Separate Tenders for the construction of the "abutments" of said bridge will be received by the undersigned up to said 20th day of January next, inclusive.

Plans and specifications of said bridge (iron work and masonry) may be seen and further information obtained, at the office of the undersigned, in the Court House in the Village of L'Orignal.

The lowest or any tender not necessarily accepted.

E. ABBOT JOHNSON,
Clerk United Counties of Prescott and Russell.

L'Orignal, December 12th, 1899.

ELECTRIC BARGAINS

We have on hand for immediate delivery a number of motors from HALF H. P. to TEN H. P. standard voltages and makers. These motors are in first-class order, some of them having had but little service, and to clear them out quickly we will sacrifice. Write us at once stating your requirements, and receive our prompt attention.

THE JONES & MOORE ELECTRIC CO.
TORONTO, ONT.

The Canadian Engineer

VOL. VII.—No. 10. TORONTO AND MONTREAL, FEBRUARY, 1900. PRICE 10 CENTS $1.00 PER YEAR.

The Canadian Engineer.

ISSUED MONTHLY IN THE INTERESTS OF THE
CIVIL, MECHANICAL, ELECTRICAL, LOCOMOTIVE, STATIONARY MARINE, MINING AND SANITARY ENGINEER, THE SURVEYOR, THE MANUFACTURER, THE CONTRACTOR AND THE MERCHANT IN THE METAL TRADES.

SUBSCRIPTION—Canada and the United States, $1.00 per year; Great Britain and foreign, 6s. Advertising rates on application.

OFFICES—62 Church Street, Toronto; and Fraser Building, Montreal.

FOR THE CANADIAN ENGINEER

WATER SUPPLIES.

BY W. M. WATSON.

(Continued from last issue.)

The need of sufficient water pressure is often a danger to the public health. Last September I was staying at a prominent hotel in one of our great cities, and while on the top flat I heard the water closet cistern (a noiseless syphon flushing cistern) syphon the water out of the cistern back into the town supply service. On examination I found that the pressure was so poor that when they drew water at a lower flat the water was sucked out of the closet cistern and drawn out of the taps below. This was very serious for the health of the household, because there would be a passage of the foul gases contained in the closet bowl upward, through the flushing pipe, and into the flushing cistern when syphoned empty, and when the cistern was refilled with water it would be fouled by these gases, and if they happened to draw the water again at the lower rooms before the w.c. was used they would be receiving poisoned fluid. A similar case occurred at the Caius College, Cambridge, where a violent and disastrous outbreak of typhoid fever occurred because one of the water closets that was flushed by a dangerous old-fashioned stool tap, out of repair, and not having sufficient hydraulic pressure behind it from the water mains, allowed the contents of the water closet bowl to be sucked back into the service pipe and delivered to the kitchen.

At Mountain Ash, in Glamorganshire, the people were struck with an epidemic of typhoid, and Mr. Spears proved it to be caused by a water main being laid for a long length alongside a very foul old stone sewage drain, and the poisonous gases had been attracted through the walls of the iron-pipe main into the motionless water when there was no one drawing. When the main was removed out of the way of the sewer the outbreak diminished and has since not occurred again. (See health reports of Great Britain for 1887.) In an English manufacturing town I examined about fifty sets of steam boilers which were supplied direct from the town's water mains and found only about twenty per cent. that were supplied with proper valves and other appliance in sufficiently good working condition to prevent the fluid from the steam boilers leaking back from the boilers to the water mains when the steam pressure in the boilers was higher than the water pressure in the mains, and sometimes the ingredients used to prevent the boilers scaling could be tasted in the water drawn at the taps of the houses situated in the immediate neighborhood.

The insuction of polluted water and foul gases into water supply mains of towns, and the illnesses caused therefrom, does not receive the attention it should, for it is of little use securing good water at the intake if it becomes contaminated after entering the town supply pipes.

But the intake end of the service should also be watched, because what sometimes seems a very trivial affair turns out to be serious. In 1892 a number of Russian Jews from the cholera stricken districts of Russia squatted on the quays of the river Elbe and the sewage from them was washed up by the tide to the mouth of the intake pipe that supplied the city of Hamburg with water, and in the space of eighty days 18,000 persons were attacked with cholera and 8,000 died from the complaint. (See Professor A. Koch's report).

During a general heavy rain or thaw of thick snow the face of the earth is washed and its impurities, coupled with the ejecta from men, animals, and birds, together with every description of decayed and putrefactive matter, is discharged into the rivers, making the waters they are carrying away totally unfit for domestic consumption for probably a whole week, and this makes it almost imperative for towns who draw their supply from drainage rivers to have a reservoir accommodation to hold over one week's supply, so that the river supply may be dispensed with during such periods, or else they should be provided with good filters.

There is a purifying advantage in storing water in reservoirs, for water allowed to rest in reservoirs for a few days improves considerably in quality if the reservoir is clean. It seems to go through a process of mild fermentation, and the friendly cleansing microbes feed on the injurious germs that the water may contain. No doubt a similar purifying process goes on in slow moving rivers, probably in a rather less degree, but it cannot be expected that the germs cast off by diseased persons and putrefactive

substances will be extracted by this process when passed into the river as sewage, because sewage waters need thorough shaking and mixing with fresh water before they both can be incorporated and the purifying influence of fresh water have a telling effect on the sewage. This fact has caused the British Government Board of Health to say that they know no river of sufficient length to thoroughly oxidize sewage fluids so as to be safe to use for domestic purposes.

Dr. Frankland assures us that dangerous microbes that cause epidemic diseases are held in suspension by the waters and do not settle down with the dead organic matters termed the heavy solids, to the bottom of the rivers or reservoirs. Dr. Thresh has proved by tests and close investigation that the poisonous germs cast off by diseased persons have been still alive and dangerous after traveling in river water for 168 miles at a speed of one mile an hour, though the germ-carrying sewage had become well clarified and clear. He also bears out Dr. Frankland's statement that the disease breeding germs are held in solution in water after the sewage is cleaned and the sediment is separated. Several noted biologists hold the opinion that when river water is specifically infected with germs ejected from persons or animals suffering from epidemic diseases they cannot afterwards be sufficiently purified to be safe for use for drinking purposes for a long period after contamination, however far they are carried with the stream.

The effect of the sun's rays upon water containing organisms is beneficial. Professor Buchner proved this by placing gelatine plates closely sown with live typhoid bacilla in water, at various depths, for a period of over four hours and exposed to the rays of the sun, when he found that all the plates that had been placed less than five feet deep were sterilized; this proves that the sun can do purifying work to a depth of five feet in clean water. Dr. Thresh and others state that typhoid ejecta loses its virulence within fifteen days, but in that space of time it may travel and convey the disease to persons 400 miles from the place from which it started.

I stated and showed clearly in my first article on water supplies that people may get accustomed to swallow contaminated water with impunity without ever being seriously and violently affected, but the act runs down the bodily system and makes life less enjoyable and shorter than if pure water was always used. This statement was proved in a very remarkable manner at the town of Newark, England. For many years that town took its water supply from the river Trent, and to be sure to have it palatable they filtered it, but the death rate for a rural, healthy district like Newark was high, and it was decided to secure the town's supply from deep wells, and abolish the use of river water. The waterworks system was totally changed in August, 1893, and proved to have a surprising beneficial effect. I herewith give the number of typhoid fever cases of that town for six years, which was supplied by Dr. Wills and published by Dr. Thresh in his reports (page 224). Newark on Trent has a population of 14,500:

	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total
1890	1	4	1	2	3	3	3	1	1	6	20	8	53
1891	25	17	8	5	5	0	12	7	14	12	15	5	125
1892	1	1	0	5	1	3	5	12	12	7	12	10	69
1893	16	16	3	5	4	5	5	8	5	4	4	2	78
1894*	1	0	0	0	0	0	0	2	1	2	3	1	10
1895	1	0	0	0	0	1	0	0	1	1	3	0	7

*The new water supply.

This table of figures speaks for itself and proves the advantages derived from a pure water supply. It is not always the best policy to extend intake pipes too far into the rivers, because the river may prove to be of better quality near the shore, and it is not hard to judge by the eye where good palatable water locates. For example I may state that this week I was over a part of the St. Lawrence River in a boat; on leaving the beach I sailed for several hundred feet over a beautiful bay of clear, bright, good water, resting on a clean stony bed, which could be easily seen at a depth of about nine feet, and appeared totally free from vegetable growth until nearing the main body of the river stream where the water turned a yellowish green and could not be seen through nearly so well. As this bay had a clean bed and was shallow for a good distance out, the water it contained would easily get aeration and have the full benefit of the sun's rays, moreover, the water coming from the surface of the main stream would be partly aerated and oxidized before it overflows sideways into the bay. This bay is really a self-cleansing reservoir kept clean at the bottom by slow circulation of the surface water of the river moving towards the beach and returning back to the main body of the river. That part of the river that is really the fringe or edge of the main stream is not of so good water, or so well sterilized as the water in the bay, moreover, it is the part of the river stream that carries the sewage from the towns situated higher up the river banks, for no sooner does sewage leave the mouth of the discharge pipe of the drain, than it makes a bee line straight down the stream and seldom passes to the main current in the centre of the stream.

In summing up the subject we may say that it is absolutely necessary to supply the public with water that is free from excrements and urine, also, any bodies or material that are in a state of decomposition or putrefaction, but I cannot admire such judgment as the citizens of Bradford, England, showed three years since when they compelled the waterworks committee to run to waste over 50,000,000 gallons of good water out of Chellow Dean reservoir because a person had drowned himself in it. The body was removed long before decomposition set in, therefore the immersion was harmless.

LAKE LEVELS.

Referring to our remarks in last issue on the subject of St. Lawrence levels, the Engineering News, New York, says: "Our contemporary is needlessly alarmed." The fact remains, however, that the situation is serious and that the outflow at Chicago by the canal will injure Canadian shipping enormously. The United States interests on the Upper Lakes may be protected by a dam on the Niagara River as recommended some time ago by the commission, and by a new Erie Canal as resolved on by Gov. Roosevelt's commission in the past few days, but these measures will not help the St. Lawrence Canals, they will make their maintenance a matter of purely Canadian interest, and it is necessary that public opinion should be educated on this important question. The Montreal Witness has an editorial under the head "Stolen Waters," recently, which takes a commendable position on this subject. The Engineering News in discussing the question refers to the capacity of the canal as "300,000 cu. ft. per second." This passing through a canal having a section 161 x 22 ft. would move at the rate of a mile a minute and the total flow per annum would equal the area of Lake Erie with a depth of say 35¼ inches. Taking our contemporary's own figures we need not be alarmed about the St. Lawrence levels, as there would be no St. Lawrence under those circumstances.

SOUTH AFRICA, ITS PEOPLE AND TRADE.

CAUSES OF THE BOER WAR.

ARTICLE IV.

(Continued from December Issue.)

The foregoing were a few out of many political grievances. On the top of these the people of Johannesburg in particular had their local or municipal grievances no less trying. The condition of Johannesburg has, like other matters in the Transvaal, been much misunderstood by outsiders. The Boer newspapers and public men have sought to make it appear that Johannesburg is made up of the offscourings of the earth, to whom it would be dangerous to give rights of self-government. In the early days, it is true, a great many adventurers came from all parts, but the town passed through that phase of life as all mining communities do; and for some years past it is no better and no worse than the average city of its size. It is not an alluvial mining diggings where men of every stamp can work their own claims, but a settled industry carried on by rock-crushing, as in the Kootenay, and necessitating expensive machinery and expert hands. Indeed, the mining machinery of the Witwatersrand is the most modern, as well as the most extensive in the world, many of the large companies having their own machine shops and operating large steam and electrical plants, with large staffs of the most skilled workmen. The manual labor is done chiefly by natives, but the mining and commercial business—the former having the cleverest mining engineers and experts in the world, and the latter, including branches of the most reputable firms of England, Germany, the United States, etc.—are carried on by white people, among whom there are practically no Dutch. Where there is so much gold production (the output last year was $75,000,000), there must be a large number of banks and financial corporations, which of necessity must have trustworthy employees, and so it must be said of business firms. Are the owners of these big mining plants, banks and financial houses likely to put their affairs into the hands of ruffians, drunkards, and thieves? If this question cannot be answered by a moment's reflection, the doubtful reader can satisfy himself by examining a copy of a recent Directory of Johannesburg, and read down the names and occupations. The same directory will show how unfounded is the statement that this agitation is purely a capitalistic one. Now imagine such a city of 80,000 * progressive and energetic inhabitants being governed by thirty farmers; and imagine the representative financial and mining body of the city (the chamber of mines) being refused an ordinary charter of incorporation, on the ground that it would be creating "a State within a State." At first, English-speaking men were chosen to the town council, but to cut them off from self-government, even in municipal matters, President Kruger decreed that only Dutch should be spoken in the council, and so the Anglo-Saxon was debarred there. And the Burgomaster (Mayor) is not elected by the voters, but appointed by the Government. The drainage of the city flows along the streets in open gutters, exhaling poisonous vapors, as was the case in the early days of Capetown, and the people are compelled to drink dangerously unwholesome water, with no power to alter the condition of things. Drunken zarps (policemen) swagger about brandishing revolvers, occasionally shooting down poor natives for some trifle, and insulting Uitlanders (who are not allowed to carry arms), whenever an excuse offers. The killing of Edgar by a squad of zarps, who broke into his house and murdered him in cold blood, as he was sitting on his bed talking to his wife, is a notorious example. The murderers were arrested, tried, acquitted, and some of them promoted. Such was the municipal condition of Johannesburg up to the present crisis.

The Boer Government of the Transvaal stands condemned by the liquor traffic. In theory, no liquor is sold to the natives, but in the large mining centres, particularly Johannesburg, the native laborers, who are herded in enclosures like cattle, are supplied with the vilest of intoxicating drinks, in such quantities that scarcely a day passes without one or more murders, brought about through drunken natives engaging in "faction fights." It is estimated that one-third of the total native labor supply is rendered non-effective, week in and week out, through natives being incapacitated by drink, while the damage to goods and machinery, through the same cause, is a serious item. So great did this scandal become that the Boer Church was shamed into strong representations against it last year, but though Kruger is himself an abstainer, he sided with the liquor dealers, and would do nothing, on the ground that if this traffic were stopped, a number of honest men would be put out of employment.

The operation of the liquor law in Johannesburg is thus described by a brother of the Rev. Chas. T. Cocking, of King, Ont., writing lately from the Transvaal: "Take the case of the liquor law, which prohibits sale of liquor to natives. Every Sunday one can see hundreds of natives wandering about the mines and suburbs of the town almost mad with drink. Kafir eating-houses are filled with natives drinking, and from which they stagger with sacks full of liquor to be swilled on the open veldt by fraternal groups. A special liquor detective department exists, and yet for twelve months this has gone on. Result? For two or three days following the debauch, hundreds of natives are unable to do their work, and remain sleeping off their carouse in the mine compounds to the dead loss of the mining companies. Cause? An immensely wealthy liquor syndicate, which, by bribery, etc., prevents the law being effective. The Government is so inconsistent as to absolutely prohibit natives from drinking, but a treaty with Portugal must allow the importation of Kafir liquors and spirits through the port at Delagoa Bay, and from the duty on which they obtain a handsome increase in the revenue."

(To be continued.)

*Besides the white population there were at the beginning of 1899, 90,000 blacks.

WATER PRESSURE.

Editor CANADIAN ENGINEER :

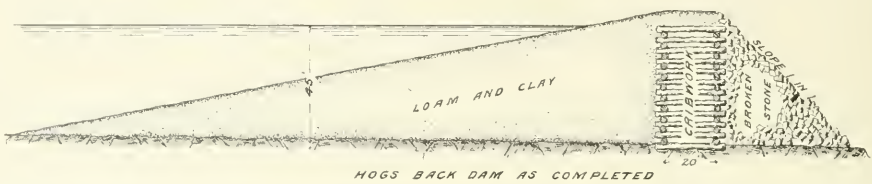
I would be pleased if the city engineer of St. John, N.B., would explain the last eight lines of the first paragraph, page 232, of December issue of The Canadian Engineer, where he shows that there was a great increase in the pressure of water because he caused three-quarters of an inch of calcareous matter to be removed from the inside of the water mains. It will be a great discovery if the head of water can be increased by increasing the size of the carrying pipe.

Toronto, January 15th, 1900. CORRESPONDENT.

THE CANALS OF CANADA.*

(Continued from last issue).

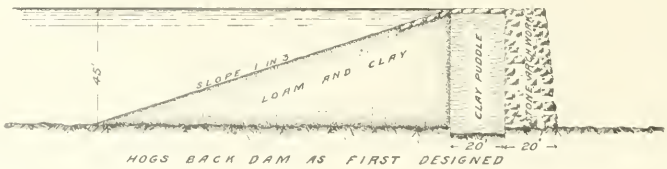
Again with a regular canal in times of flood the engineer simply closes his guard gates and lets the angry river sweep by, but if he has dammed right across it he must be prepared to cope with and tame its fullest strength. More than one dam, built in the most approved materials of modern engineering, has gone down before such floods, and the best method of building such structures is still a matter of controversy. The boldness of these pioneer engineers can be best judged by their own recital of the disasters that befel their first dam. This was the Hog's Back dam, which is situated close to Ottawa, and at a point where the level of the water had to be raised 45 feet. The river was 170 feet wide, and in 1827 a dam was constructed half way across the river. It was built on the authorized plan; that was, an earth structure which was rendered water-tight by clay puddle and supported on a great dry stone wall built in an arched shape of large stone set on edge. Then the contractor attempted hurriedly to block the other half of the river by a dump of what



HOGS BACK DAM AS COMPLETED

the Royal Engineers called rubbish, but no provision was made for the water, and rising, it swept over the rubbish and carried it all away. A rough timber dam was then thrown across the opening in order to protect the finished part of the arch, but the spring floods overtopped this, swept it also out and cut a new channel around one end of it. The gap was again closed in the simple method followed by our lumbermen in building their driving dams, and under this protection the great arch was at length completed, and by March, 1830, the dam seemed safe. But the river rising in spring flood worked through the ill-packed clay and puddle, and on April 3 the stone work fell with a great crash, and the river swept on its course once more. The Royal Engineers write that they saw that day an extraordinary exhibition of the power of Canadian frost, for while the turbulent stream swept through, the top of the dam remained standing, an earth arch of over 50 feet span. The dam was finally completed by building the lumbermen's cribs right across, backing them with broken stone, and dumping earth and clay in front, and providing ample by-passes for the flooded river. The lessons its construction taught have been well learnt, and no man would to-day build an earthen dam that the river could overtop, nor attempt any construction without providing ample by-passes while his works were in progress. The still recent failure of the dam on the South Fork of the Conemaugh river was caused by the blocking up of its waste weirs or by-passes, and the destruction of Johnstown and of the railroads in the Conemaugh valley was a terrible demonstration of the power of a flooded river that has broken its dams. The Rideau Canal is a succession of pools formed by dams like that at the Hog's Back, lift locks being built near the end of the dams. These were of rubble masonry laid in lime mortar and faced with cut stone. Considerable difficulty was experienced with the masonry owing to the poor quality of puddle used around the walls, and the total unsuitability of lime mortar for such work. This was finally overcome by making a special cement at Hull, for our modern hydraulic cements were then unknown, and grouting the finished walls with it through long tin tubes let down in holes drilled in the masonry. The vertical lift of these locks varied considerably, but it was necessary at some places to place several locks together to overcome the rise at those points. Thus at Ottawa a rise of 81 feet is overcome by eight locks in a flight.

The delay and inconvenience to traffic of such an arrangement has been found to be very considerable, and in the canals now building it is carefully avoided. The Trent Navigation is a system of canalized rivers connecting natural lakes, very similar to the Rideau, but on that work the engineers are building hydraulic lift locks where a great rise is to be overcome at one point. These are a distinctly modern device, and pending the completion of the Trent lock, the most notable of them in service is that at La Louviere on the Belgian State canals. The upper and lower reaches of the canal are closed by vertically sliding doors, and the lock is simply two great steel troughs, carried on girder work very similar to that of a railway bridge. The troughs are closed at the ends by doors like those on the ends of the canal, and each trough runs up and down between braced steel guide towers. Under the centre of each trough is an enormous ram, and the cylinders in which the rams work are connected together so that one lock in descending forces the other to rise; and in practice the lock is actually operated by allowing the water in the upper trough to become a little deeper than that in the lower, the weight of this extra water supplying all the power required for the lift. The trough becomes part of the upper or of the lower reach according to its position, the gates being run up far enough to clear the barges. The rise at La Louviere is 50½ feet, and the lock will lift barges carrying 400 tons. The Trent lock will have 15 feet more rise and will handle much heavier boats. The time of passage through one of these locks will not differ materially from that required for a gate lock, but it has a much greater lift, the maximum on the Canadian gate locks being that recently adopted for the Soulanges canal, 23¼ feet; it has also the advantages of giving a passage up and a passage down at the same time, and of requiring very little water to operate it; a feature which recommends it strongly to the Erie canal engineers, that work being badly handicapped by lack of water. It is not at present considered suitable for the great locks of the St. Lawrence system.



HOGS BACK DAM AS FIRST DESIGNED

That the Royal Engineers were wise in their decision to raise the levels of their rivers rather than attempt to excavate canals, seems to be proved by the history of the first Welland canal, which was built at the same date. It was proposed that there should be no locking up from Lake Erie, and the "deep cut" near Allanburgh was undertaken with that end in view. An excavation varying from 30 to 55 feet was required for about a mile and three quarters through a heavy clay, underlaid with treacherous unstable material resembling quicksand. When this was about two-thirds completed tremendous slides occurred blocking the canal and rendering necessary the raising of the summit level, and the building of a 21 mile feeder to obtain water to operate that level. Those slides remained an obstacle

*From a popular lecture by J. G. G. Kerry, B.Sc., before the Applied Science students of McGill University.

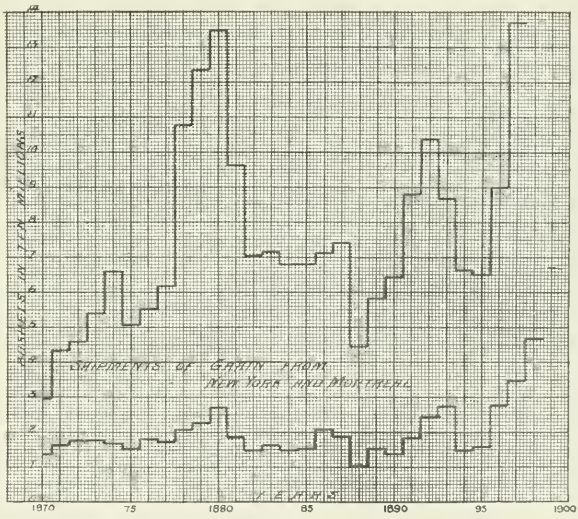
to our commerce until after 1870, for in spite of all improvements and enlargements it was not until that date that the cut was excavated to such a depth that the Erie level could be carried through.

The Soulanges canal may be taken as the most advanced type of canals proper. It is a built canal for its entire length of 14 miles, and has a waterway 100 feet wide at the bottom, with side slopes of 2 to 1. The banks of the canal near the water line are protected from the wash of the swell of passing vessels by a layer of broken stone. The excavation of the material for the waterway involved enormous quantities, but the perfection of modern contracting plant rendered it easy to handle the material at rates that would never have been thought of in the construction days of the Rideau; and, although its route did pass through material well nigh as unstable as that on the Welland, the great slips that have occurred have been readily taken out by the contractors. The Soulanges canal has no lack of water to fear, for its summit level is that of Lake St. Francis, and like all the St Lawrence canals it has the great river to draw from. But though the flow of the St. Lawrence may be ample its depth is not always so, as the shippers of Montreal well know from recent experiences in the ship channel, and in this particular the engineers of the Soulanges have made more ample provision for unprecedented low water than has been made at Lachine and Cornwall, for on those canals of nominal fourteen feet draught, the water has sometimes been less than thirteen feet deep. There is also grave reason to fear that the opening of the Chicago Sanitary Canal will divert so great a flow from the St. Lawrence that in low water seasons the river level will sink lower than ever before, and that the efficiency of our most important canals will be seriously impaired by this local American work, for unfortunately, the time of low water is coincident with the time of heaviest trade, and then every inch of draught means much to our forwarders. As in the Rideau, the heavy fall of the Soulanges comes at one point, but here in order to avoid a flight of locks short stretches of canal with large equalizing basins are built in between the separate lifts. The locks themselves are built of concrete, and faced with cut stone. Their magnitude can only be realized when standing in them, for the size of a wall 22 feet thick, and 41½ feet high, is not easily grasped from the figures alone.

There are several details that are worthy of note in these locks. The breast walls at the upper end are reintroduced, as it is found that the most fruitful cause of accident in canals is the collision of an upcoming boat with the upper gate, and breast walls will prevent this. The gate valves for letting the water in and out of the locks, and that we are all so familiar with, have been abandoned, and the water flows through great culverts in the heart of the wall. The flow through these culverts is regulated by vertically moving valves called Stony sluices, a device adopted from the Manchester Ship Canal. The familiar winches for operating the gates will also be missing for these, themselves nothing but a pile of great beams of British Columbia fir solidly bolted together, will be moved by heavy struts attached a little above the centre of the gate and working in recesses in the walls. The power for all this movement, and for the lighting of the canal from end to end at night will be electricity, and will be obtained from a special power-house, built in the bank of the canal, and utilizing its surplus flow.

Special channels or by-passes are built around each of the locks by means of which water for the reaches below can be supplied without flowing through the locks themselves. These by-passes are spanned by stone bridges at each end, and the discharge through them is controlled by a set of automatic Stony sluices built directly across the by-pass at the centre. Long walls of cribwork run out into Lake St. Louis and Lake St. Francis at either end of the canal, but there is a novelty in their design also. For the cribwork is only carried up to within a foot of low water, and above that these quay and anchorage walls are all concrete.

The line of the canal is intersected in several places by roads and streams, and provision has had to be made for their crossings. The roads are carried on swing bridges as is customary, but these are specially designed so that there is no masonry to interfere with the clear waterway of the canal, and an extra channel is excavated around the swing pier of the bridge. The opened draw is completely on one side of the canal proper. The piers are of concrete and the scaffolding in the slide is typical of that used for all the structures. It is not an easy matter to cross a large stream with a canal, for the level of the canal is usually about that of the stream, and although the latter's low water flow might be a desirable addition to the resources of the canal, its flood tide would be far too strong to be accommodated in so artificial a channel. The main stream that crossed the Soulanges location had a flood discharge greater than that of the Rideau at the time of the Hog's Back disaster, but it and all other streams have been quietly passed under the canal by means of lines of cast iron pipes, set in concrete. The Delisle River required 4—10 ft. pipes to give it free passage. The St. Lawrence canals are all built to the same general dimensions, but the details of the Soulanges are more complete than those of the earlier finished canals. The locks are much larger than those of the Ottawa and Chambly canals, but are after all only modern developments of the original type which they well illustrate.



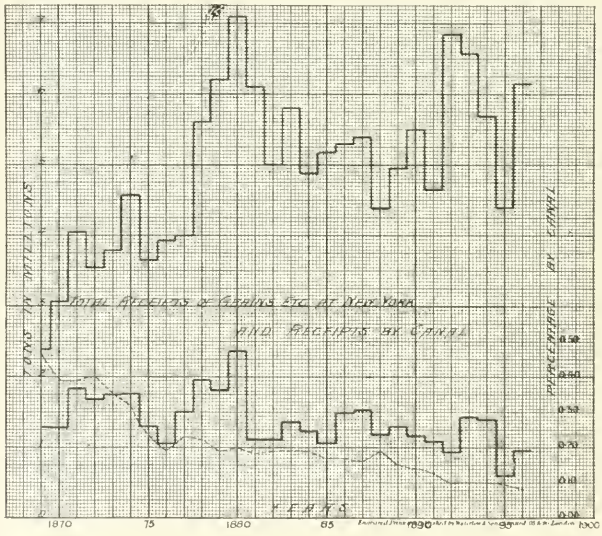
Turning now to consider the canals from the point of view of the commercial public, it must be admitted at the outset that they have failed to fulfil the expectations of their designers. In the case of the smaller canals the reason for this is not far to seek. In England and in the United States no stocks have

suffered such a tremendous decline as those of the canal companies, which at the beginning of this century were considered the most desirable of investments; and the same competitor that has ruined, and so often absorbed those canal companies, has taken away from our canals most of the freight that they were designed to handle. Half a century ago, just on the completion of our St. Lawrence system, T. C. Keefer, C.E., was quietly prophesying that in a few years the railroad would leave nothing for the river but "emigrants, pork, flour and lumber," and the event has proved him to have been more than right. In Europe, the canal remains a great and valued part of the transportation systems, but the conditions that make barge canals profitable there are not found here. The American transportation problem has been a peculiar one, and it has worked out its own solution largely in special long-haul low rate freight railroads, which have been developed to meet the needs of a restless and energetic people, of great commercial activity and impatient of all restraint, struggling against the disadvantages of a northern climate and of a sparse population scattered over widely extended areas. The smaller canals, both in Canada and the United States, have not been able to hold their own against such competitors.

The traffic on the St. Lawrence system is worthy of a more detailed study, for it was built for the one purpose of winning for the river the export trade of the west, and it has not done

last thirty years it has resulted in a steady diminution in the canal traffic, although the tolls have been steadily reduced, and finally abolished in 1882.

It was in the hope of capturing this Erie Canal traffic that the St. Lawrence canals were built, and the great expenditures made by the Canadas in the early days do not appear so extravagant, when we remember how great was the toll collected by the rival route at that time. Col. Philpotts in his report, previously referred to, pointed out how marked would be the superiority of the St. Lawrence route if its canals were made large enough to permit the passage of the lake vessels to Quebec without breaking bulk, and how great a share of the traffic such an improvement would divert, but he does not seem to have fully considered the influence of the vested interests and established trade routes of New York. The clearest proof of the impossibility of natural advantages alone changing the channels of trade is in the fact that although the Welland was long the smallest of our canals, about half of the traffic passing through it was diverted from the St. Lawrence route and sent to New York through the Erie canal via Oswego by American forwarders. This fact is but another tribute to the superior energy and resource of our New York competitors. Col. Philpotts' idea was that the lake carriers should be brought through to Quebec with full cargoes, but this was rendered impossible by the small size selected for the Welland locks on its enlargement in 1848, and the possibility of car-



so. The principal reasons of this failure are the commercial inactivity of the Province of Quebec, the disproportion between the canal locks and the vessels carrying the lake trade, and the great changes in the positions of the world's manufacturing centres since the system was first projected. That we have been completely outdistanced by New York in the struggle for the western trade must, in large measure, be attributed to the superior commercial genius of its people. Early in the century the New York statesmen saw that the Great West, then just opening up, must become commercially tributary to the St. Lawrence, unless they could provide a competing water route, and with the steady purpose of securing that trade they completed in 1825 the Erie Canal. Perhaps no transportation work has ever been so completely successful both politically and commercially. It fully achieved its purpose, and from the hour of its completion New York became the commercial capital of North America. For many years it was crowded beyond its utmost capacity, its locks worked continuously night and day, and the revenue from its tolls was so great that when the railroads parallel to it were first opened they were forbidden to carry freight lest they should diminish the income of the State. But with the removal of this embargo, and the development of railroading consequent upon the introduction of the Bessemer steel process, the competition grew more and more keen between the two systems, and for the

rying out his idea has never yet arrived owing to the fact that the dimensions of the lake carriers have always increased more rapidly than those of the locks of our enlarging canals. With a strange lack of foresight, in which, however, they were amply justified by the statements of the most prominent forwarders of the day, the Canal Commissioners of 1871 determined the dimensions of our now nearly finished system; and after pointing out that when Col. Philpotts' recommended locks of 750 tons capacity there were then boats of 800 tons on the lakes, and that there were boats of 1,600 tons at work in their own day, and that no man could prophesy what the increase of a few years would be, they calmly recommended locks that would not pass the largest vessels of their own day; so that when the enlargement of the Welland was completed in 1887 it was more out of date than it was in 1871. Vessels at present carry about 1,800 tons through the Welland, and will be able to descend to Montreal upon the completion of the Soulanges, but the great grain carriers of the lakes now run over 6,000 tons. T. C. Keefer, writing in 1893 recommends that the locks of the canals be lengthened, as the first step in their further improvement, pointing out that although in modern steamers the proportion of breadth to length varies from 1 to 8 to 1 to 10, our commissioners adopted those of Noah's ark and made the locks 1 to 6. The most economical size and draught of steamers is a matter of controversy, and for

ocean steamers the largest are now greatly preferred, but Mr. McDougall, the designer of the whaleback lake fleet, for which the highest efficiency in service is claimed, has stated recently that of all their boats, they believe that those suited to the Canadian canals will make as good a showing as any of the larger vessels. The promoters of the Trent Navigation are of the same opinion, and claim that the present craze for large lake ships is without satisfactory foundation, and say that they will be able to compete on even terms for the grain trade over their land-locked barge route from the Georgian Bay to Montreal; but the truth of this claim remains to be tested. The failure of the Erie Canal in its struggle against the railroads, they ascribe to a communistic law which forbids any company with a capital of more than $50,000 to operate on that route. As the great transportation companies now reach after their traffic for thousands of miles, it can easily be realized how hopeless it is for a small barge owner to secure the carrying of that traffic for but a portion of the way.

The completion of the Erie Canal by centering the export trade at New York made it also the importing centre of the continent, and the forwarder by the Erie route was nearly sure to secure a return cargo for his boats, and the influence of the great importing firms thus tended to draw the export traffic from the St. Lawrence, and it would only have been by the growth of a mercantile community in Montreal equal in wealth and enterprise to that of New York that that advantage could have been offset; and any attempt at American importation via the St. Lawrence was rendered impossible by the attitude of the United States custom officials. The disproportion of trade in the St. Lawrence, and also in the export and import trade of Montreal itself has always been very great. This

centre Montreal is unfortunately greatly handicapped by her distance from a winter port, and it is much to be desired that the late suggestions of T. C. Keefer with regard to keeping the St. Lawrence open in winter should be given a thorough trial. This has frequently been pronounced altogether impracticable, but until it has been thoroughly tried with modern ice-breaking steamers no man is really in a position to make this assertion. If the river could be kept open even to Quebec the advantage to Montreal, and to all routes leading to Montreal would be very great. The canals themselves will, of course, never be kept open for more than eight months as an absolute maximum. It is well to state here, however, that although competitively our St. Lawrence canals have not succeeded, they have always been of great absolute importance to this city for almost all the grain for export, and a large proportion of the lumber, has been brought by barges, and it is its great export rather than its import trade that maintains the harbor of Montreal. The canals were for many years the practical link that held the Canadas together. The facilities that they furnished contributed greatly to the building up of Ontario, and they have been indispensable to purely Canadian trade, and have only failed in the effort to turn the trade of New York to Montreal.

There are three canal schemes now attracting the attention of the Canadian public. The first is the old Trent Navigation, commenced in 1837 and discontinued in 1841, and again taken up about 1882 by the Dominion Government. Several references have been made to it in this lecture, and active efforts are being made to secure the necessary appropriations for its completion. It will open up a local trade route of great length, and its promoters expect by a well organized barge service to secure a large proportion of the through eastward traffic.

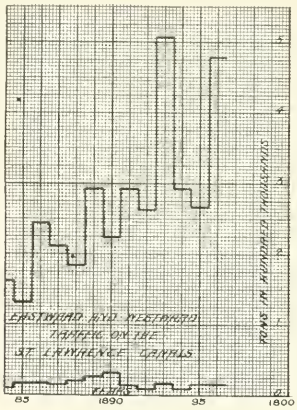
impossibility of securing return cargoes has been keenly felt by our forwarders, and the early canal builders hoped that the low freight rates that could be made by the St. Lawrence would induce heavy shipments of coal, iron and salt up the river, but the growth of the manufacturing interests on the lakes, where these raw materials are now mined in greatest abundance and at the lowest figures in the world, have destroyed this hope of westward traffic.

For the future our forwarders can only hope to compete for the grain export trade, of which we handle at present but a tithe, although our shipments for 1898 were unprecedented. This increase must, however, be largely ascribed to the activity of the Canada Atlantic Railway which, unlike the Canadian Pacific and the Grand Trunk, catered vigorously for the grain trade, and at prices practically equal to those offered by canal. It will therefore be a matter of great interest to observe in the future the contest between our 14-ft navigation, and this energetic railroad, which is so situated that the grain traffic is almost an essential to it. Certainly the cost of grain transportation has now become much less than the fluctuations of the market price of that commodity. We have also something to hope from the development of heavy manufacturing interests, now taking place in the Province of Quebec; for an active commercial population here would contribute more to the prosperity of our canals than any other probable event. It is also possible that, if the present hostility to our interests evinced by our American neighbors continues, we may be forced to build against them a tariff wall, as high as that which they have so persistently erected against us; and that will mean that much of the coal and iron that is now imported from the States will have to be brought from England and the lower provinces, and will move westward over the cheapest route, that is by the canals. As an importing

The western shippers have long been anxious for a deep waterway canal to the sea, and this has been reported as feasible by an International Commission. The commissioners advised the examinations of the three following routes, by the St. Lawrence River to Montreal, by the St. Lawrence River, Lake Champlain and the Hudson River to New York, and by Lake Ontario, Lake Oneida and the Hudson River to New York. The St. Lawrence route would prove very much the cheapest, but this enterprise is never likely to be undertaken as an international work, because the great bulk of the traffic of the Western States is now with New York and Boston and their surrounding cities, and not with Europe. The Lake Oneida route will therefore best serve their trade, and as this is a purely American route, that would not in any way tend to the building up of Canadian shipping, and to the increase of an independent Canadian commerce, Canada has no interests in it; while the St. Lawrence route by not leading directly to the Eastern States would not be a benefit to the larger portion of the American trade and would not be considered by the United States.

The proposition that was made to the Dominion Government during the last session of Parliament for the building of a 14 foot canal via the old route of Champlain and the fur traders from the Ottawa River to the Georgian Bay, renders possible the construction of this work at an early date, but it is doubtful if the offer will be accepted by the Government. Considered as a canal it could not under present conditions be made a paying investment as our Government canals are at present operated at a heavy annual loss to the country, but the enormous water power that would be made available by the construction of the proposed system of locks and dams on the Ottawa and on the French Rivers is a commercial prize well worthy of attention. This is estimated at a million h.p., after making all allowances

ior losses in development, an amount that can only be realized by remembering that it is more than twelve times the horse-power of all the engines in Montreal. The Montreal Board of Trade has opposed this proposition on the ground that a route of such importance should not be alienated to a private company; but in view of the history of Canadian transportation affairs it is doubtful whether this ground is sound, even though the scheme itself may not call for commendation. It is certain that our heavily subsidized railroad corporations have shown an energy and enterprise in developing our trade, and in operating their systems to the satisfaction of our shippers, and of the travelling public that we would never expect from a Government work, and have carried on their extensions with a financial success that the Intercolonial has never had. In Mr. Keefer's essay of 1850, that has been already quoted, he remarks bitterly that the subject of canal development is subordinated to the wrangling of rival lawyers; and from the present result of Governmental control in Montreal harbor, and the recent refusal of the Canal Department to make their repairs so as to get the canals ready to be opened at the date the forwarders requested, it would appear as if our politicians had not greatly advanced in states-



manship since 1850, and that for the present, the interests of the country are better served by highly privileged and subsidized companies, whose very existence depends upon their developing our natural resources, than by Government action under the control of party politicians, who cannot afford to exercise any foresight, but must fight day by day to maintain their hold on the narrow majorities on which their tenure of office depends.

MANUAL TRAINING IN PUBLIC SCHOOLS.

The system of manual training about to be introduced experimentally into the public schools of Canada by the Dominion Government, through the generous endowment given by Sir Wm. McDonald, is almost the same as that in use in some of the English schools, and is described by Jas. W. Robertson in a pamphlet recently issued.

The system of education is called English Sloyd. Sloyd is a Swedish word for "dexterity." Educational Sloyd is an entirely different thing from carpentry. The manual training room is not a workshop where operations are carried on with a view to the commercial value of the articles turned out. A workshop is a money-making institution, whereas a room for manual training for Sloyd work—in connection with a school, is for the training and developing of the children, without regard to the intrinsic value of the work turned out, or to the length of time required to make any particular object. Sloyd work is really a series of exercises so arranged as to have educational results.

A floor area of about six hundred square feet is enough to accommodate about thirty pupils and one bench for each. A room 24 x 30 feet would be amply large; and would provide also for the instructor's bench, and for a group of pupils to watch what he was doing. Ten classes of thirty pupils each, or three hundred in all, could be passed through such a room in the week. The benches are of convenient height and size, and each one is fitted with a rack for the holding of tools and also with tools. Some of them are also fitted with a simple device for the holding of the drawings, so that the work with the tools may proceed with the drawing in full view all the time. General class instruction with the aid of a blackboard is given by some teachers in a fifteen minutes' talk, before the particular work of the half-day begins; and instruction is given also to each of the pupils individually as the work at the benches proceeds.

In some schools the first object to be made is a plant label. This involves (1) cutting to an exact length, (2) cutting the ends square by the use of a fine saw, (3) reducing to the proper thickness and width, and (4) making a taper with the same angles as those of the model. In other schools a small pointer is the first model; and in others some object equally easily made. The first article is easily made; the second introduces some slightly different use of a tool or the use of some different tool; and so they proceed, arousing, training and gratifying the child as he makes all of each one himself. It is to be remembered that the pupil makes each article wholly himself. At first he makes directly from the models. Later on he makes drawings from drawings of the models. Further on he makes his own drawings directly from the models. Then finally he is trained to make the articles from his drawings of the models. The course may be arranged on a plan of from thirty to sixty or more articles to be made by the pupil during the three years.

The lectures of Otto Salomon, the renowned director of the Seminarium for teachers at Naas, Sweden, furnished valuable suggestions on the choice of models and on the arrangement of the series of models. An authorized edition of those lectures is published under the name of "The Theory of Educational Sloyd." From it the general principles relating to the series of models are given: (1) All objects of luxury—knick-knacks—should be excluded. From an educational point of view, we must first teach what is necessary; secondly, what is useful; thirdly, if time permits, what is agreeable. These terms are, however, relative.

What is necessary to one person may be useful to another, and what may be useful to one, agreeable to another. What is a luxury in one age or country, is not necessarily so at another time or place. What is a luxury to a poor man may be a necessity to a rich. In regard to nature the terms are more absolute. What is necessary to one is necessary to all. It is necessary to eat food; it is useful to eat food sufficient, and of good quality; it is agreeable to have it well cooked and prepared.

(2) All models should be serviceable in the house. If this is to be the case, the models will vary to some extent in different schools. Not only will the models be different in different countries, but in different districts of the same country; e.g., in country schools it would not be wise to teach the manufacture of objects only useful in towns. It would be preferable to substitute models which may be used in agriculture; but in substituting other models, care must be taken not to disarrange a carefully graduated series of exercises. So, too, if the school be near a lake, objects concerning boats and fishing should receive attention. The general principle by which we should be guided is: That the series of models made in the school should give the best expression to objects needed at home or in the district.

(3) They should be capable of being finished by the children without help. Hence models should not be a part merely of something, but the whole. For this reason it has been found necessary to exclude many things which would otherwise have made useful models.

(4) The models should be of wood, and only wood should be worked in, as a rule. To this rule there are one or two exceptions, as the cloak suspender, the clothes rack, and bucket; and these have been inserted because teachers in the country districts of Sweden cannot buy them, but there is no reason why they should be retained in an English series. When it is said that the models must be made of wood, it is not implied that there is any objection to the purchase of iron fittings.

(5) The objects should not be polished or stained. In the first place, because children cannot polish well. Models are frequently spoiled by it. Many juniors cannot polish well, i.e., French polish. In the second place, it is important that children should not be taught to think too much of the surface. It is not so important that a thing look well, as that it be done well. Polishing and wood carving exert a morally bad influence, if done to cover up bad or indifferent work. It is a degradation of

the polisher's and carver's arts to use them for such a purpose.

(6) The objects made should be such as to require as little wood as possible. Some models require much wood, but if the same exercises can be furnished by smaller objects equally useful, then these should be preferred. The value of the object must be in the child's work, and not in the amount of material used. This recommendation has a further value, inasmuch as it teaches the child to use small means in effecting ends. Children should be trained to be economical by taking care of those pieces of wood for smaller objects which they have spoiled in making larger ones.

(7) The children should be taught to work in harder and softer kinds of wood—but not in the hardest or the softest. (8) Turnery and carving should be used very little. (9) Objects chosen should be such as will develop the sense of form. (10) All the exercises (embraced by the particular kind of Sloyd in question) which the child is capable of making, should be properly graduated and included in the series in due proportions.

(1) The series should proceed from the easier to the more difficult, and from the simpler to the more complex; which expressions, as we have seen, are not identical in meaning. (2) A refreshing variety must be afforded. (3) In the early part of the series, the models should be capable of being quickly and easily made, and should be so progressively arranged that, later on, the objects arrived at should require more time and skill, and yet be capable of being done without help. Children expect to have results as quickly as possible. They have not sufficient patience and foresight to derive any benefit or satisfaction from results which are expected to crown their labors in a few days or months. For this reason the objects further on in the series should take more time, in order to cultivate patience and foresight. (4) In the production of the early models, few tools should be required, but as the series progress, new tools and manipulations should be introduced. (5) That every model should be so placed in the series, that the necessary qualifications for doing it exactly are found in the child, who therefore does not need the help of the teacher. It should not relatively be more difficult for a child to do one model than another. A model may be more complex, but this does not imply an increase of difficulty; for the child—when it reaches it—has acquired greater skill. A person who has used one tool will use a second better, although it be of another kind; he will use a centre bit better for having previously worked with a knife. (6) The models must be so arranged that the pupils can always make not only a serviceable, but an exact copy. The degree of exactness is a very important feature. It is easy to make a table if exactness be not required. (7) That the knife—as the fundamental tool—be used frequently especially at the beginning. By the fundamental tool, we understand that tool with which the child is most acquainted and can most easily use, hence we begin with it; secondly, that tool which cultivates the greatest amount of manual dexterity; and thirdly, the tool which in after life will be most useful to the child, and most ready to hand. These advantages the Sloyd knife possesses. We must not be understood to imply that this tool is the one most used throughout the series of models. (8) That generally in the early models the softest wood should not be used. It is more difficult to use a knife on a very soft wood than on a wood not so soft; so that it is advisable to avoid using the softest kinds of pine and fir.

THE PRACTICAL MAN.

IRON AND STEEL.

The following is from Fowler's Mechanical Engineer's Pocket Book for 1900, which contains some five hundred pages of valuable information:

1. Pig Iron.—Impure iron containing over 1.5 per cent. of carbon, and large quantities of other impurities always made in the blast furnace. Used for castings, and as the raw material for the production of malleable iron and steel.

2. Malleable or Wrought Iron.—Nearly pure iron. Has not been fused since the removal of the foreign constituents, but has been prepared by the welding together of small masses of spongy iron. It always contains particles of slag and oxide, the elongation of which during rolling produces the fibre. Commercial malleable iron is always made by puddling.

3. Steel.—This includes all varieties of iron containing less than 1.5 of carbon except malleable iron. It may have been fused as in crucible cast steel and mild steel, or it may have been prepared in the solid condition, as in blister steel and puddled steel; the latter is rarely if ever made now. When the steel contains less than .5 per cent. of carbon it is called mild steel, when more, hard steel. Hard steels harden when they are heated to redness and quenched in water.

PIG IRON—CONSTITUENTS AND IMPURITIES.

Pig iron is very impure, containing carbon, silicon, phosphor, sulphur and smaller quantities of other impurities. The carbon and silicon may be considered as being essential constituents. It is always smelted in the blast furnace. The iron ore, which contains oxide of iron and silica, and other earthy impurities, is charged into the furnace with coke and limestone, and air being blown in the coke burns, and a very high temperature is produced. The iron is reduced, and, combining with carbon and other substances present, forms pig iron. As various reducible constituents are always present in the materials, the iron always contains impurities. Carbon is the essential constituent in pig iron, the smallest quantity which will entitle the iron to be called pig iron is 1.5 per cent., and the largest amount the iron can take up—except in presence of large quantities of certain foreign elements—is 4½ per cent. The carbon is present in two forms, (1) in a state of chemical combination, (2) as intermixed flakes of graphite. The graphite has very little effect on the iron, except that it breaks the continuity, and thus weakens the metal. The combined carbon is one of the most important constituents. Its influence is to harden the metal, and, within limits to increase its tensile strength. It may vary in amount from about .08 in a soft No. 1 iron to 1½ or more in a white iron. The graphite is the carbon which is not combined. Silicon.—This constituent is always present in pig iron. Its action resembles that of carbon in many ways, and there seems to be no limit to the amount that can be taken up. Silicon has within limits a good effect on the iron, but when in large quantities makes it hard and brittle. Turner gives the amount of silicon which is best as being:

For maximum hardness, under	.8
For maximum crushing strength, about	.8
For maximum modulus of elasticity, about	1.0
For maximum density in mass, about	1.0
For maximum tensile strength, about	1.8
For maximum softness and working qualities, about	2.5
For lowest combined carbon, under	5.

Silicon has two actions, (1) a direct hardening action similar to that of carbon, only much less energetic, and (2) a tendency to throw the carbon out of the combined, and into the graphite condition, the second action being usually the more important. Thus when an iron contains, say 2.5 per cent. of silicon, this will harden the iron to some extent, but it throws the carbon almost entirely into the graphitic condition, and thus prevents the much greater hardening influence which the carbon would have if combined. Grey pig iron is usually high in silicon, whilst white is low. The amount of silicon depends largely on the temperature at which the iron is made, the higher the temperature the more silicon is reduced, so that modern hot blast irons are higher in silicon than those made years ago, when the air was sent in at a lower temperature. Sulphur is rarely present except in small quantities. It has a powerful hardening effect, tending to throw its carbon into the combined condition. It thus counteracts the action of the silicon, and the lower the silicon the more injurious is a small percentage of sulphur. Phosphorus is always present, the quantity varying from a mere trace up to three or four per cent. Phosphorus increases the fluidity of the metal, makes it run well, and set slowly; in large quantities it makes the iron hard and brittle. Manganese.—This element is almost invariably present. Like silicon it has a direct hardening action, and an indirect softening action, the latter being due to a strong tendency to eliminate sulphur. Aluminum tends to throw its carbon into the graphitic form more energetically than silicon. It also improves the soundness of castings. Hematite or Bessemer Pig. This iron is made from hematite or other pure ores. It must not contain more than about .05 per cent. of phosphorus, and .01 per cent. of sulphur, and is usually high in silicon. It is used for

the manufacture of Bessemer and Siemens steel, and more rarely for foundry work. Scotch Foundry Pig.—This is largely used for foundry work. It contains from .7 to 1.1 per cent. of phosphorus and about 2.5 per cent. of silicon. It is an excellent iron for foundry purposes. There are various brands to be had, but as a rule there is but little difference between them, certainly not enough to warrant its great difference in price, the prices seeming to depend more on reputation than on actual composition of the pig.

Staffordshire All Mine Pig.—This is a pig iron made in Staffordshire from ore without the addition of cinder pig. It contains .5 to .75 per cent of phosphorus.

Cinder Pig.—This is made in Staffordshire from tap cinder, it is usually high in phosphorus, and is often blown, i.e., full of cavities.

Cleveland Pig.—This is a pig iron made in the Middlesborough district from Cleveland ore. It usually contains about 1 per cent. of phosphorus and 2.5 per cent. of silicon.

Basic Pig.—This is a pig iron made specially for the manufacture of basic steel. It contains 1 per cent. or less of silicon, and from 1 to 3 per cent. of phosphorus.

Cold Blast Pig.—Is iron made in furnaces supplied with a cold blast; it is usually low in silicon.

Charcoal Pig—Is pig iron made in furnaces in which charcoal is used as a fuel. It is now rarely made.

Silicon Iron, or Siliconeisen—Is a pig iron containing 10 per cent. or more of silicon. It is made for special purposes, or occasionally by accident, which is usually called glazed iron. It is white in color, hard and brittle.

Spiegeleisen—Is an alloy of iron and manganese, containing 20 per cent. or so of manganese. It breaks with a fracture showing large mirror-like crystalline pieces, with a high metallic lustre—whence its name.

Ferro-Manganese—Is an alloy of manganese and iron, often containing over 80 per cent. of manganese. It breaks with a granular fracture of a bronze white color. Spiegeleisen and ferro-manganese are used in the manufacture of mild steel.

Chrome Iron—Is an alloy of chromium and iron.

Ferro-Aluminum—Is an alloy of iron and aluminum

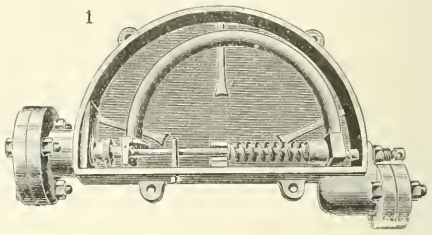
GRADING PIG IRON.

Pig iron is classified into a series of grades, usually 1, 2, 3, 4, mottled white, though the classification varies in different districts. No. 1 is always the grayest iron, and the last, whether indicated by a number or a name, is white. No. 1 is the grayest iron, the fracture is largely crystalline, flakes of graphite being distinctly seen. It is soft and has a low tensile strength, but flows readily when cast. It is usually high in silicon, high in graphites and carbon, but low in combined carbon (about .15 per cent.). No. 2 is similar to No. 1, but the crystallization is less distinct; it is stronger and harder than No. 1, and contains more combined carbon. No. 3 is still closer in grain, and the crystals of graphite are small and hardly discernible It is stronger and harder than No. 2, and contains usually less silicon and more combined carbon than the lower numbers. No. 4 is very close in grain, and breaks with a dark gray, granular fracture. It is harder and stronger than the lower numbers, but does not flow so freely when melted. It is often subdivided into two. No. 4 (foundry) is, with Nos. 1, 2 and 3, useful for foundry purposes, and No. 4 (forge) is too close and hard, and is only used for the preparation of malleable iron by puddling. White Iron—Is very hard and brittle, and has a low tensile but high crushing strength The silicon is usually low, sulphur often high; the fracture is smooth, almost silver white, and shows no graphite, the carbon being almost all in the combined form Mottled Iron This consists of matrix of white iron, with spots of a close grained gray iron scattered through it It is therefore intermediate between white iron and No. 4 No. 4 forge—mottled and white—irons are only used for conversion into malleable iron.

The grade is judged entirely by the appearance of the fracture and the system of grading is most unreliable and unsatisfactory, and there is no standard by which a grade can be judged One of the great needs in the iron trade is a better system of grading The only system which has been suggested is based on the percentage of combined carbon, but as this could only be determined by analysis, it is not likely to displace the present rough and ready system

A STEAM TRAP.

One of the most interesting exhibits at the recent Export Exhibition in Philadelphia was that of the Heintz Steam Saver, the Canadian agents for which are the James Morrison Brass Mnfg. Company, 89 Adelaide street west, Toronto. The device was shown in many forms and applications, and for the purpose of better observation, the pipes leading to and from such traps as were in actual service had sections of gauge glass inserted, so that an ocular demonstration was possible, that proved exceedingly interesting to many steam users who had occasion to study economy as well as efficiency. The great development that has taken place in the past five years of the Heintz plants was a topic of much comment amongst people familiar with it. When the inventor, M. Heintz, of Liege, Belgium, first began business in 1874 he was his own workman, salesman, bookkeeper and engineer, and it was several years before he had advanced sufficiently with his efforts to justify his employing an assistant. The development was remarkably rapid from that on, and to-day his plant forms one of the most striking in a locality that abounds in large industries. He employs some six hundred people in this one factory alone, and has others in France and the United



States. To-day the American sales are said to be enormous. The field of usefulness for the Heintz traps is proportionately greater in Canada than in the United States, for the reason that the necessity is greater owing to the severer winters and long continued cold weather; and it is not unreasonable to look for a larger business for this article in the near future. The Canadian agents make a most favorable showing to prospective customers, and it would seem as if, from the nature of it, no steam user could afford to ignore it. It is at least possible under their proposition to ascertain definitely whether or not a steam plant is as well equipped as it is capable of being, without this experiment or trial costing the user any money, if it proved to be unsuccessful, and it would seem as though an offer of this character would appeal to every user of steam.

The inventor claims (and his claims are said to be substantiated by users), that the adoption of his device will save from 10 to 50 per cent. in fuel, and at the same time increase the efficiency of the apparatus trapped, from 10 to 40 per cent.

It is a singular fact that the Heintz trap or Steam Saver enjoys no patent right protection. Anyone who thinks he is capable of doing so, is at liberty to make them, and in the past twenty years, something like fifty or sixty companies have been organized for the purpose of making the effort. That these companies all failed, one after another, speaks volumes for the acumen displayed by Mr Heintz in not taking out patents for his perfected apparatus; the reason he gave at the time being that as it required seven years constant effort on his part to discover how to make the Heintz trap, he did not believe it was possible for any one else to find out any more quickly than he did.

—The B. F Sturtevant Co., of Boston, Mass., reports an increase of nearly 40 per cent in the volume of its business for 1899 over that of the previous year The shipments, both foreign and domestic, included fan blowers for all purposes, heating, ventilating, drying and mechanical draft apparatus, engines, electrical apparatus, etc. During the past year an addition, covering 20,000 square feet, has been made for the use of the electrical department, which has shown the most rapid growth, the output having more than doubled during the year, and covering principally electric fans and special generating sets The sale of mechanical draft apparatus has been practically quadrupled, while the output of engines has increased one third over that of the preceding year, and has included many special designs.

COMBUSTION.

C.A.S.E. Executive Office,
Lesson Paper No. 4.

Heat and motion are so intimately connected together that you cannot have one without the other. Any body of matter that is absolutely still would be at absolute zero, or 461° below zero on Fahrenheit's scale. Tyndall tells us that heat is motion; and by combustion we mean the combination of chemical elements commonly called burning. All matter or any body of any material is either an element, a compound or a mixture. Iron, gold, silver and oxygen are elements; wood, water and carbonic acid are compounds. Any substance that can be decomposed or divided into other substances is called a compound. Lime may be divided into two other substances, calcium and oxygen, and is a compound. There are many substances that cannot by any known process be subdivided into other substances, such as gold, sulphur, iron and arsenic; this being the case they are called elements. The elements we will consider are hydrogen, and its symbol is H; oxygen, O; nitrogen, N; carbon, C; sulphur, S. In referring to these elements the symbol is the first letter of its name; as C for carbon, etc. When two or more elements are brought together under favorable circumstances, they will combine and form a new substance entirely different from either of the elements.

Hydrogen is a very light gas and burns with a steady blue flame, and it burns because of a chemical combination with the oxygen of the air, and the product of this combination is water. Just as chemical combination produces heat, so will chemical separation absorb heat. If carbon and oxygen are brought together at a high temperature they form carbon dioxide; hydrogen and oxygen form water; hydrogen, nitrogen and oxygen when combined under certain proportions form nitric acid. Ammonia is formed by a combination of nitrogen and hydrogen, and is a very different gas from either of its components. In making these combinations a certain amount of heat is produced, and if these elements are separated they will absorb exactly the same amount of heat produced by their combination. It is supposed by chemists that equal volumes of all gases, whether simple as elements or compounded, contain the same number of molecules, and that each molecule is composed of two atoms. Suppose that hydrogen and oxygen are in contact with each other and are heated, they will combine and form steam or water. It will be found that two atoms of hydrogen will be seized by one atom of oxygen to form one molecule of water, therefore the volume of hydrogen must be double that of the oxygen. Hence we have for a symbol H_2O, that is two parts of hydrogen to one of oxygen. Hydrogen and carbon also form a compound, each atom of carbon seizes four atoms of hydrogen and forms a molecule of marsh gas, the symbol for which is CH_4.

Mixtures may be formed of two or more elements that may be mixed together, but will not combine to form a new substance. The ordinary atmospheric air is an example. It is composed of oxygen and nitrogen; 23 parts by weight of O to 77 parts of N; these two gases are not chemically combined, they are only mixed. Combustion is only a very rapid chemical combination, in which the oxygen of the air combines with the carbon in the fuel. Oxygen has an attraction for nearly all the elements, but more especially for carbon, and when they meet at their igniting temperature they combine with great rapidity, and make a roaring fire, and give out a great quantity of heat, as in a boiler furnace.

The elements that enter into combustion are carbon, oxygen and hydrogen. When carbon and oxygen combine they form CO_2, or carbon dioxide, and when oxygen and hydrogen combine they form water, H_2O. These are the products of combustion.

In our furnaces we take the oxygen from the air, and the nitrogen passes through the fire with it, but takes no part in the combustion. Now CO_2 or carbon dioxide is composed of 12 parts by weight of carbon to 32 of oxygen. Hence to burn a pound of carbon requires $32 \div 12 = 2\ 2\text{-}3$ lbs. of oxygen, but it will take 11.6 lbs. of air to supply the $2\ 2\text{-}3$ lbs. of oxygen, because only 23 per cent. of the air is oxygen; 1 lb. of carbon, if combustion is complete, will give 14,580 B T U., and the product is CO_2, or carbon dioxide; but if carbon oxide, CO, is the product the result is only 4,451 B T U. At the commencement of combustion 1 lb. of carbon (C) unites with 2.66 lbs. of oxygen, and forms 3.66 lbs. of carbon dioxide, setting free 14,580 heat units. The volume of the CO_2 is the same as that of the air from which it was formed, but its density is greater and the combustion is complete; but if the air is wanting in quantity the 3.66 lbs. of CO_2 absorbs 1 lb. of carbon, making 4.66 lbs. of carbonic oxide, CO, or marsh gas, and the heat set free by these 2 lbs. of carbon is 8,902.8 heat units, or 4,451.4 per lb. of carbon. The combustion of a lb. of carbon to make (CO) only requires ½ the quantity of oxygen that is necessary to form (CO_2), because in the gas (CO) one atom of carbon seizes only one atom of oxygen instead of two. To burn 1 lb. of carbon to carbon dioxide (CO_2), requires 11.6 lbs. of air, while to burn it to carbon oxide (CO) would only require 5.8 lbs. of air. The quantities of air required for combustion of fuel can be seen from the following table:

1 lb.	Air at 62°	Product.
Hydrogen	34.8 lbs. or 457 cu. ft.	Water, nitrogen.
Carbon burned to CO_2	11.6 lbs. or 152 cu. ft.	Carbon dioxide, nitrogen.
Carbon burned to CO	5.8 lbs. or 76 cu. ft.	Carbon monoxide, nitrogen.

The air required for the combustion of a pound of fuel is easily determined if you know the percentages of carbon and hydrogen it contains. Example: Your coal contains 90 per cent. carbon, and 10 per cent. hydrogen; now to burn the carbon you would need $152 \times 90 \div 100 = 136.8$ cu. ft. of air, and for the hydrogen, $457 \times 10 \div 100 = 45.7$, $45.7 + 136.8 = 182.5$ cu. ft. of air.

Rule to find the air required to burn a given fuel: To the carbon in the fuel add three times the hydrogen, multiply the sum by 1.52, and the result will be the cubic feet of air required. Example: Composition of coal being carbon, 84; hydrogen, 5; oxygen, 7; ash, 4; to perfectly burn 1 lb. of such a fuel by the above rule: Ans.$= 1.52 \times (C + 3H) = 1.52 \times (84 + 3 \times 5) = 150.8$ cubic feet.

The quantities of heat produced by complete combustion of the elements composing fuels are for

Hydrogen—62,000 B T U per lb.
Carbon to CO_2—14,580 B T U per lb.
Carbon to CO—4,400 B T U per lb.

The chief consideration for economical combustion is the correct air supply. It is not possible to attain perfect combustion with the theoretical amount of air, which is 11.6 or 150 cubic feet per lb. of coal, because in the conditions obtained in our furnaces we cannot get the air into perfect contact with the burning carbon of the coal, for this reason we have to supply about double the quantity of air or 24 lbs. If more air than is actually needed is allowed into the furnace it simply carries heat from the furnace to the chimney, while if too little is used we get marsh gas instead of carbon dioxide. If it were possible to heat the air during the short time it is going through the fuel up to the heat of the fuel the theoretical amount would be all we would require for perfect combustion; one of our losses in the furnace is the driving off by the heat of the hydrocarbons contained in all our bituminous coals, before these coals really begin to burn. These gases are driven off, and are very likely to escape unburned up the chimney. The admission of a small quantity of air above the fire will sometimes burn them. If they are not burned they escape as black smoke.

The best smoke burner in the world is a fireman that knows how to handle his fires in well set boilers with ample draft.

A. M. Wickens, Secretary.

—The new addition to the works of the B. F. Sturtevant Co., Boston, Mass., which was designed to meet the requirements of its rapidly growing electrical department, is already overcrowded, although completed only a few months ago. Numerous special orders for electric fans and generating sets for the U. S. navy are being filled, and the construction of a complete line of enclosed motors of new design is now under way.

RAILWAY BUILDING IN MANITOBA.

Manitoba has seen a considerable extension of its railway lines during the past year. Construction was carried on upon thirteen lines, of which twelve were in Manitoba, and one in Northwestern Ontario. In the territories west of Manitoba no new railway building has been done, except the Pipestone branch of the Canadian Pacific Railway, which was built across the Manitoba boundary and on westward some miles into Assiniboia territory. The southern half of the province of Manitoba is fast becoming a network of railways, says The Winnipeg Commercial in a recent issue. The new mileage for the year was 351 miles. The province of Manitoba has 2,000 miles of railway. During the past year the C.P.R. Co. has carried on new railway construction at points within Manitoba, including the extension of the Northwest Central and the short link connecting the latter railway with the Rapid City branch of the Manitoba and Northwestern. These two roads are both now controlled by the Canadian Pacific Railway Company. Two new branches in Southern Manitoba, known as the Snowflake and Wascada branches, respectively, are short feeders to the Deloraine branch, affording better railway facilities to well settled agricultural districts south of the Deloraine branch. These two new branches have been completed and are now being operated. The Snowflake branch has a total length of a little over 17 miles, and the Wascada branch, which starts at Deloraine, is something over 18 miles long. A little north from Deloraine we have the Pipestone branch, where a considerable amount of work has been done. An extension of 17 miles was graded on this branch during the summer of 1898, westward from Reston. This 17 miles was completed during the past year, and an additional 23 miles has been graded, and is now mostly ironed, making 40 miles of new road added to the Pipestone branch during the year. This branch is giving much needed railway facilities to a fairly well settled agricultural section. About fifteen miles of the new portion of the Pipestone branch, west of Reston, is in Manitoba and the balance of 25 miles is in Assiniboia territory. The C.P.R. has extended the Northwest Central 22 miles west of the former terminus at Hamiota, and the extension is fully completed and in operation. A town called Miniota has quickly grown up at the new terminus of the line. A three-mile link has been built at Rapid City, between the Northwest Central and the Manitoba and Northwestern Railway. The McGregor-Varcoe branch of the C.P.R. will be about 48 miles long and one-half was graded this season. The Lac du Bonnet branch will run 22 miles from Molson Station on the C.P.R. to Lac du Bonnet. Ten miles are now under construction, and will be completed before spring.

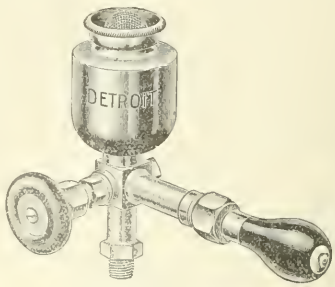
The Northern Pacific Railway has constructed about 30 miles of new railway in Manitoba during the past year. This consists of a new branch, extending in a northerly direction from the town of Portage la Prairie, a distance of nine miles, toward Lake Manitoba, and also an extension of the Portage la Prairie branch in a northwesterly direction, from Portage la Prairie, a distance of 20 miles. The new branch extending toward Lake Manitoba will be known as the Lake branch. The terminal of this branch has been named Oakland. The road runs through a fine wheat country.

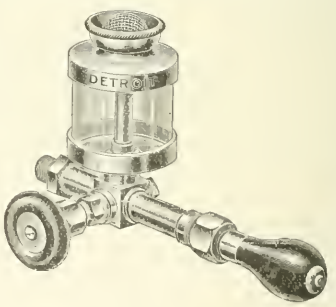
The first section of the Manitoba Southeastern was built in 1898, extending from St. Boniface to Marchand, a distance of 46 miles. The work was taken up again last spring and is still being pushed. Over 50 miles have been completed, and it is the intention to continue the work until the road is ironed to War Road, in Minnesota, making in all an addition of about 68 miles for this season's operation.

The Canada Northern Railway has continued operations as was expected during the past year. During 1898 this new road was extended in a northerly direction from Sifton to Cowan, a distance of 56 miles. During 1899 a further extension of about 65 miles has been made, from Cowan to a point about 11 miles beyond Birch River. Leaving Cowan, the new line runs in a westerly direction about 30 miles to Swan River, and then turns north again, passing to the east of Porcupine mountain. This road is opening up an entirely new country, in the northern part of Manitoba, which is well adapted to mixed farming and stockraising. There are also large and valuable timber areas which will thus be opened up. The length of the main line of the Canadian Northern, with the addition now about completed, is 240 miles. Construction was begun during the past year on a new branch, running about due westward from the town of Dauphin. This road is known as the Gilbert Plains branch. Work is going on on this branch still, the object being to complete 15 miles at once, and a further extension of probably about 20 miles will be made during 1900.

INTERCHANGEABLE OIL PUMPS.

The accompanying cuts show the new style oil pumps that have recently been put upon the market by the Detroit Lubricator Co., Detroit, Mich. An advantage claimed for them, over the ordinary styles, is that the body can be easily removed from the frame should it be desirable to do so for the purpose of removing any dirt or sediment deposited by the oil, without removing the oil pump proper from the steam pipe. Each style is made with both vertical and horizontal connection shanks, and the bodies of the whole four styles, of the same sizes, are interchangeable. For instance, the body of the brass body oil pump with vertical connecting shank can be interchanged with the glass body of the pump shown with horizontal shank, etc. Each style is also equipped with strainer filler. The manufacturers have issued a pamphlet showing these oil pumps, also their new style glass and brass oilers, and will send same to any address on application.





—By Order-in-Council, passed January 18th, the Ontario Government has prohibited the export of pulpwood cut on Crown lands after May 1st. This is a step in the direction of home manufacturing which has been urged so often in The Canadian Engineer.

—An ingenious arrangement to prevent overcrowding of stairways and elevators when entering or leaving a building is used in the main office of the International Correspondence Schools, Scranton, Pa. The time of entering and leaving the building is regulated by clocks on each of the five floors. On the lower floors the clocks are set correctly, but on the upper floors they are a few minutes slow, so that the employees on the lower floors are at their desks before those on the upper floors are due at the building. In leaving the building the employees on the upper floors do not leave their desks until several minutes later than those on the lower floors. Over 500 people are employed in the building, which is used exclusively by the International Correspondence Schools. This institution has over 70 courses of instruction by mail, and its students may be found in all parts of the world

OILSTONES, HOW TO SELECT AND USE THEM

If the iron be blunt and he do not whet the edge, then must he put to more strength.—Ecclesiastes x., 10.

No article in a mechanic's kit of tools is of greater importance than the oilstone, for no matter how good the quality of his edge tools, they cannot do good work unless properly sharpened. If it were possible to show in figures the total loss in damaged tools and wasted time resulting every year from the use of poor and unsuitable oilstones, the sum would be amazing—far exceeding, doubtless, the total amount of oilstones sold. Notwithstanding this fact, very few mechanics and still fewer tool dealers understand the particular merits of the different oilstones on the market, or how to select them for different purposes. The object of this article is to give a few practical suggestions on the selection, use and care of oilstones, in such terms that the amateur as well as the experienced mechanic may obtain a clear understanding of the subject, and benefit thereby.

Far in the past, while man was fighting his way up from his barbaric condition to civilization, the sharpening stone was one of his most important tools. Old stone implements and weapons discovered in caves, mounds and excavations in various parts of the world give evidence of this; for among those ancient relics have been found stone arrowheads and crude axes with sharp or ground edges. At first, it is probable that these were ground down by rubbing on large rocks. Later on in man's progress, when it was discovered that metal made better edge tools than stone, the sharpening stone became a still more important factor; more care was taken in selecting the kind of stone for grinding these tools, and instead of rubbing the tools on large boulders, he evidently broke off small pieces of rock and faced them by rubbing together.

Many pieces of hones and whetstones of various kinds have been found in the excavations of Pompeii and other ancient cities. Coming down to the time when the art of transmitting written records had been learned, we find whetstones referred to frequently by the earliest historians. The word "whet," as referring to the sharpening of swords and iron tools and weapons, occurs several times in the Bible, and the historian Pliny, writing over 1800 years ago, tells us that there were many different kinds of stone used in those days for sharpening iron instruments. He states that the best ones came from Crete, and gave better results when used with oil. As the well-known Turkey oilstone is still found in Crete, although quarried principally in Asia Minor, it is probable that this is the stone Pliny refers to, which would indicate that the Turkey stone has been in use for nearly two thousand years. It was the principal oilstone of the civilized world until the discovery of Arkansas and Washita stones in the early part of the present century. These two kinds of stone, which are the same geological formation, but vary in hardness and fineness, were discovered in the Ozark Mountains of the state of Arkansas, U. S., somewhere about the year 1815, when it was quickly perceived that they were superior to anything ever found for sharpening edge tools. In those days of slow and costly transportation it was very expensive getting the stone into eastern markets, the rough rock bringing as high sometimes as $2 per pound. In spite of this, the remarkable sharpening qualities of these stones rapidly increased the demand for them, until to-day they are the two leading oilstones of the world.

The first point to be considered in selecting an oilstone is the purpose for which it is required; many mechanics make the common mistake of expecting one oilstone to answer all purposes. It would be just as reasonable for a carpenter to use a coarse-tooth crosscut saw on fine cabinet work, as to expect a coarse-grained fast-cutting oilstone to impart a fine razor edge. The sharpening qualities of a stone depend upon the size of its grains of grit, or crystals. In a coarse-grit stone, these grains are large, and cut deep, far apart furrows in the tool, leaving a coarse, rough edge. Such stones cut away steel faster than a fine-grained stone (as a coarse-tooth saw cuts faster than a fine-tooth). The coarse edge left by such a stone is all right for working pine or soft woods in which the cells are large, but for working hardwood or any kind of fine work, the tool should be finished on a finer-grained stone. It is therefore safe to lay down the rule that a good mechanic should have at least two oilstones, one for grinding down dull tools, or imparting a coarse edge, and another for finishing. There are some stones of medium grit which answer well for many purposes, but they cannot cut as rapidly as the coarse stone, nor impart so smooth an edge as the fine. A carefully selected Washita stone is stated to be the best general purpose oilstone. The hardness of an oilstone is also an important factor in determining its cutting qualities. For sharpening ordinary tools with broad blades or edges, a medium-soft, fast-wearing stone should be chosen. For sharpening narrow chisels, engravers' tools or pointed instruments, however, it is necessary to use a very hard stone, as otherwise the stone will soon be cut full of grooves or furrows. The difference between a hard and soft Washita stone can be told in several ways; first, by the sight, as in a soft stone the minute pores are usually apparent to the eye, and the surface of the stone will have an open, granulated appearance; second, by scratching with a knifeblade, as a soft stone can be quite readily scratched on the edges, whereas a hard stone will show very little impression; third, by the sound, holding the stone loosely by one end between the thumb and fore-finger and tapping it with a knife, light hammer or any metal substance; the soft stone will sound dead like wood, whereas a hard stone gives forth a metallic ring. Having decided for what purpose the stone is to be used, the next thing is to find a stone that has the desired qualities. This leads to the consideration of the principal oilstones on the market.

The oilstones most widely in use at the present time are: The Washita, Arkansas, Turkey and Hindostan. Although these stones are well known to most mechanics, a brief description of them may not be out of place. The Washita and Arkansas stones are quarried in the state of Arkansas, near the celebrated Hot Springs. They are found in parallel veins, or "mineral leads," and are quite similar in general appearance, both being white or nearly so, but the Arkansas is very much harder, more compact and finer grained than the Washita. There are various qualities of Arkansas and Washita rock, from a perfect, fast-cutting grit to the vitreous, flinty rock that is practically worthless. To the ordinary observer, the appearance of the good stone and the worthless is so nearly the same that it is always advisable to buy the known brand of a reliable manufacturer. At frequent periods, since these stones first came on the market, inferior qualities have been put out by irresponsible or inexperienced manufacturers, which has done serious injury to their reputation in some localities. For the past few years, however, the output of the best quarries has, it is stated, been controlled by one firm.* As this firm has taken great care to select and manufacture only the best rock, both reputation and demand have rapidly increased.

The Arkansas stone is found in two grades, known as hard and soft. Hard Arkansas is composed of nearly 99½% pure silica (one of the hardest, sharpest cutting minerals), and is about 16 times harder than ordinary marble. Steel will not scratch it, but it, in turn, will cut the hardest steel very rapidly. It is white or bluish white in color, and by reason of its very fine, hard grit, is particularly adapted to sharpening fine tools requiring very keen, smooth edges, such as are used by engravers, watchmakers, diesinkers, wood and ivory carvers, surgeons, etc. Owing to the very limited supply of good Arkansas rock, and to the great difficulty in quarrying and manufacturing it (about 85 per cent. being waste), it is necessarily very high-priced, a first-quality stone being worth $2.50 per pound at retail. A stone of extra large size or special shape is worth even more than this. Soft Arkansas is of the same composition as the hard, but is more porous, hence does not impart quite so fine an edge. It is used very largely by machinists, workers in hard wood, cutlers and mechanics in general as a finishing stone. It is carried in stock by most tool dealers, and generally sells at about one third less price than hard Arkansas.

The Washita oilstone is the most widely used by carpenters and joiners. It has crowded the Turkey stone almost entirely out of America, and is fast superseding it in Europe and other countries. It is composed of nearly pure silica, but is much more porous than the Arkansas stone. It is stated by geologists that a cubic inch of perfectly crystalized Washita stone contains over eight million (8,000,000) cavities, or pores. It is the presence of this vast quantity of evenly distributed pores which enables the grit grains, or crystals (the teeth of the stone) to work freely and thus make it the fastest cutting fine-grained stone.

*The Pike Manufacturing Co. of Pike Station, N.H

There is no oilstone in which greater experience is required to select understandingly than the Washita, for it can be found in all degrees of hardness and fineness. For ordinary carpenters' tools, such as planes, bits, chisels, gouges, etc., a medium-soft, even-grained, fast-cutting Washita should be chosen. The Washita stone is put on the market in several qualities by the Pike Manufacturing Co. The Lily White brand is selected by experts from the very best rock; each stone is tested and labeled, telling whether it is a soft, medium coarse or a hard, medium fine grit. Every Lily White stone, whether of coarse or fine selection, is of uniform grit throughout, free from hard or soft spots, or streaks, and of sharp-cutting grit. The No. 1 quality Washita is a well-finished stone, free from cracks, quartz or noticeable imperfections. It is the most largely used brand on account of its lower price, but as there are both hard and soft stones in this grade, and they are not labeled nor warranted, the stone should be selected by a thoroughly experienced judge. The No. 2 quality Washita is, as its name would imply, a second-quality stone. It usually contains some quartz streaks, "sand holes" or other imperfections. In addition to the above-named grades of Washita stone, there is also a brand known as the Rosy Red, which is very similar in cutting qualities to the Lily White, except that it is generally a little softer and coarser. This stone is streaked with orange or dull red color, which in no way affects the grit, but indicates a soft, porous nature. It is a guaranteed brand, and is well adapted for grinding down dull tools or wherever rapid work is required.

The Turkey oilstone, already mentioned, was the leading oilstone for mechanics' tools for many centuries previous to the discovery of the Washita. It is bluish gray in color, with frequent white spots and streaks. It is composed of about 70 per cent. silica, mingled with 30 per cent. lime, clay and iron. The white spots and lines are calcite, or lime, which wear away quickly, leaving holes and rough cavities in the stone. The stone also frequently comes apart in these lines as soon as it is oil soaked. It is nearly impossible to get a perfect Turkey stone, that is, one which is free from these lime streaks or other imperfections. A good Turkey stone will impart a fine edge, but no finer than a fine-grained Washita, while it does not cut steel so fast. It sells for about the same price as Lily White Washita, but very few Turkey stones are now sold in America. Hindostan, although usually called an oilstone, can be used with water with equally good results. It is a very fine-grained sandstone, and is undoubtedly the best low-priced sharpening stone for mechanics' tools. Its cutting qualities are due to small grains of silica, which are remarkably uniform in size in this stone. It is a fast-cutting stone, but owing to its softness, the powder or grit which is cut from the stone soon forms a mud that clogs the pores and makes it cut more slowly unless the stone is kept free by the plentiful use of water. By using a little oil and leaving this dust on top of the stone a fine surface is given the stone, which produces a very fine edge on the tool. It is a very good stone for imparting a quick medium coarse edge, and is used very largely by amateurs and those who do not have to use an oilstone very often. It is sold in three grades, as follows: Export extra quality, which is the finest grained, hardest Hindostan, white or yellowish white in color; Washita finish quality, which is well finished, grayish white stone; and the No. 1 quality, which is generally a very roughly finished stone and varies in color from a bluish gray to almost a yellow. Hindostan stones generally retail at from 10 to 35 cents apiece, according to size and quality.

In our next issue we will deal with other oilstones, and how to use them, also giving a few remarks about stones made from corundum and emery.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.

The officers and members of Montreal No. 1, C.A.S.E., met at the residence of J. J. York, mechanical superintendent of the Canada Sugar Refining Company, January 27th, to present him with a handsome silver tea set and tray appropriately engraved. The presentation was made by the treasurer, T. Ryan, with a few well chosen remarks on behalf of the members of the association. Mrs. York was also presented with a bouquet of roses. After thanking his friends for their present to Mrs. York and himself, Mr. York invited all present to supper, and a pleasant evening was spent in songs, etc.

J. M. Williams, chemist for the wholesale drug firm of Winer & Co., gave an address before the Hamilton Branch C.A.S.E. at the monthly meeting, January 16th. The subject was "Boiler Feed Water," and it was skilfully handled, the speaker illustrating his subject as he went, on a blackboard. Mr. Williams divided his subject into several parts, viz., water in the abstract, water as we find it, water for the boiler, and water in the boiler. Under the first head he explained the component parts of water and their chemical relation. Under the second head, the different kinds of water, rain, spring, lake and salt water were dwelt on, and their merits pointed out. The third division, water for the boiler, was dealt with at some length, Mr. Williams stating the condition and quality of water to be used for such purpose. The altered condition of water subjected to heat and the actions of chemicals was also dealt with. Finally, the speaker explained the cause of the formation of scale on a boiler and the various kinds of corrosion that boilers are subjected to.

C.A.S.E., Toronto No. 1, held its regular meeting on Wednesday, January 17th. The attendance was good, and the members had a treat in the way of a paper by E. J. Philip, on "Ice Making and Refrigerating Machinery." The date of the annual "At Home" was fixed, and it will be held in the Confederation Life Building on Wednesday, February 14th.

WE ARE WELL HATED.

Wm. Kennedy, C.E., of Montreal, has returned to Canada after an extensive tour through Great Britain and the Continent. As may be imagined, one so observant as Mr. Kennedy would see a great deal of interest from the standpoint of a civil engineer, as well as from that of a politician. In noticing the development of manufactures on the continent, particularly in countries like Switzerland and Austria, it was curious to observe how a Chinese conservatism can exist side by side with the most revolutionary notions of scientific progress. In the immediate neighborhood of a factory operated by a modern electric plant and equipped with the latest machinery one may see some old mill whose primitive wooden machinery is moved by an ancient undershot or overshot water wheel, or a lumber mill containing wheel pits where saws are still operated partly or wholly by hand. And yet the old mill seems to have a fair hold on life, if not positively thriving in these lands. Mr. Kennedy confirms the reports brought by so many other tourists of the prevailing hatred of Britain throughout Europe, even among those nations who have not so much as a sentimental cause of quarrel with the British people, and whose national liberties, if British power were destroyed, would not be worth a week's purchase. This hatred seems to be born at least partly of ignorance of Great Britain's real position and motives, and of this ignorance there appears to be a colossal stock among otherwise well educated people. A highly educated Swiss gentleman, who could speak several languages, asked Mr. Kennedy with the utmost seriousness, whether there was really any friendly feeling in Canada towards Great Britain. In the course of conversation this gentleman disclosed his real notions concerning this country, which were that Canada was held in subjection to Great Britain by military force, and that Canadians were only awaiting a good opportunity to "shake off the yoke," and that any contributions in men to help the Mother Country in the Boer War were raised by a sort of conscription such as ruled in Germany or France. It is needless to say that the fantastic reports circulated through the Leyds' agencies regarding Britain's relations with South Africa are fully believed by the average European, while it is difficult for any friend of Great Britain to get a hearing among these people.

NEW CATALOGUES.

We have received the catalogue of the Standard Tool Co., Cleveland, O. It contains some 80 pages, devoted to the goods made by this firm, and differs but slightly from catalogues published by the original makers of twist drills in the United States, the main point of distinction being a red label in the shape of a shield which ornaments the top of each page, and other blank spaces.

ONTARIO MINERALS.

The following table presents by quantities and values the statistics of metallic production in Ontario for nine months ending September 30, 1899, and for twelve months ending December 31 in the years 1896 and 1893 respectively, as published in the Report of Bureau of Mines, Vol. VIII, second part:

Metals	1899 (9 mos.)		1896 (12 mos.)		1893 (12 mos.)	
	oz.	$	oz.	$	oz.	$
Gold...	20,210	318,212	7,154	121,848	1,695	32,960
Silver..	98,000	58,800	.....	.....	.....	.....
	lb.		lb.		lb.	
Nickel.	4,608,000	566,633	3,897,000	357,000	3,306,000	454,702
Copper.	4,642,000		3,736,000	130,660	2,862,000	115,200
	tons.		tons.		tons.	
Pig Iron	48,216	693,455	28,302	353,780	.....	.....

No silver was produced in the province in 1893 or 1896. The mines were closed down in 1892, and were not reopened until 1898. The first production of pig iron after an interval of more than thirty years was in 1896, and the first production of gold after almost as long an interval was in 1892. The total value of metallic products in 1893 was $602,862, and in 1896 $963,288. For the nine months of the present year it has been $1,637,100, and if the same rate of production be maintained to the end of the year it will reach $2,200,000. The total value of the metals produced in the province for the twelve months of last year was $1,655,968, made up of $290,919 gold, $51,960 silver, $514,220 nickel, $268,080 copper, and $530,789 pig iron. The revenue from sales and leases of mineral lands has been $147,665 for the nine months of the present year, as compared with $97,762 for the whole of 1898, $40,588 for 1896 and $26,159 for 1893.

"TEMPERATURE."

Editor CANADIAN ENGINEER :

Under the above heading in your January issue the following question is worked out in detail:

"If water is at the temperature of 60° F., how many pounds of it will it take to condense 1 lb. of steam at 5 lbs. pressure, the resultant water to be 110° F. ?"

The answer is given as 20.8 lbs.

The following will show that an error has been made. The water is raised from 60° to 110°, or each pound takes up 50 heat units, and as the total number of heat units to be taken up is 1,073, therefore $\frac{1073}{50} = 21.46$ lbs. water required.

Let x = number of lbs. of water required.
t = initial temperature of water.
t_1 = final temperature of water.
H = heat units in steam.

The loss of heat from the steam = the gain of heat by the water

$$H - (t_1 - 32) = x\,(t_1 - t)$$
$$H - t_1 + 32 = x\,(t_1 - t)$$
$$1151 - 110 + 32 = x\,(100 - 60)$$
$$\therefore\ x = \frac{1073}{50} = 21.46 \text{ lbs.}$$

The error arises in treating one quantity "from 32" and the other from zero, making a difference of fully 3 per cent. This error is commonly made in calculations of the kind.

Toronto, January 24th, 1900. A. WOOD.

AMERICAN STOKER CO. VS. GENERAL ENGINEERING CO.

In our October issue a short history was given of the case of the General Engineering Co., of Ontario, Ltd., vs. the American Stoker Co. and the Dominion Cotton Mills Co., of Montreal. The original action, the reader may remember, was brought to recover damages for the infringement of the patents held by the General Engineering Co. on the Jones Underfeed Stoker, and to restrain the defendants from using or erecting these stokers in Canada. The action was carried by the defendant companies from one court to another, till it reached the Exchequer Court, to which it had been taken when our last report was given. The Exchequer Court had given a strong judgment in favor of the General Engineering Co., granting the injunction asked for and restraining the defendants from setting up or using any of the Jones Underfeed Stokers in Canada, with damages. This judgment confirmed the rights of the General Engineering Co. to the Jones' patents, which the American Stoker Co. was adjudged to have infringed. A new point was now raised for the first time, we understand, in connection with the Canadian patent law, and that was the contention by the American Stoker Co. that the Jones patent became invalid in Canada by reason of the expiry of the British and Italian patents for the same invention. In a judgment handed down last month the court held that the American Stoker Co. were not entitled to a writ of *scire facias* for the repeal of the patent in question on this ground. The judgment, however, did not go into the merits of one of the questions raised "as to whether the Canadian patent referred to means a patent issued here after the foreign patent has been issued, or if it means a Canadian patent applied for after the foreign patent has issued. The identity of the Canadian and Italian patents was disputed, but was not dealt with by His Lordship, neither was the question of whether the expiration of a foreign patent by forfeiture before its potential term expired would operate as a termination of the Canadian patent." The court gave permission to the defendants to test these points in a new trial, but the evidence in such new trial would have to be limited to these points, and would not affect the judgment previously given in favor of the General Engineering Co. The American Stoker Co. is thus prohibited from doing business in Canada in the meantime, and should the new trial sought for be pushed and decided in its favor the General Engineering Co. has other subsequent patents on the Jones Stoker as improved, and which patents would not be affected by any decision on the point here raised.

MARKETS OF CANADIAN GOODS IN GREAT BRITAIN.

Harrison Watson, curator of the Canadian section of the Imperial Institute, London, England, is in receipt of the following enquiries: A Liverpool house desires to hear from Canadian manufacturers of wood blocks for mangle rollers for which they could place several orders. An importing house possessing a connection with picture frame makers asks for names of Canadian manufacturers who can supply oak mouldings. A Midlands firm of manufacturers wishes to hear from Canadian importers of elastic boot webs, boot looping, garter webs, skirt bindings, ladies' belts, etc. The manufacturers of a patent metal seek a Canadian resident agent of good standing. A London dealer in high-grade goods would like to hear from Canadian packers of smoked salmon in thin slices, in oil, in tins. A Glasgow importer would like to hear from Canadian manufacturers of cheap bedroom furniture. A Bristol house is open to import ash hay-forks and hickory pick-handles. A Glasgow firm of merchants possessing a connection with the confectionery and wholesale grocery trade seeks agencies of Canadian products. They also have a house in China and are open to consider agencies for the far east. A Paris, France, commission agent asks for samples and prices of Canadian wood bicycle rims for which he has an opening.

FIRES OF THE MONTH.

Jan. 11th, J. I. Lloyd's foundry and machine shop, Kentville, N.S.; loss, $15,000; now rebuilding.——Jan. 15th. R. S. Porteous, Stratford, Ont., furniture factory; loss, about $5,000. ——Jan. 20th. Cox & Johnson's box factory, Vancouver; loss about $3,000.——Jan. 25th. S. Bicknell's cheese box factory, Peterborough; loss, about $3,000.——Jan. 30th. F. W. Shaw's pork packing house, Forest, Ont.; loss, $7,300.——Jan. 31st. Drying house of the Empire Tobacco Co., Granby, Que.

HEIRS WANTED.

Editor CANADIAN ENGINEER :

Sir.—I am looking for the heirs of Braddock Nyle, who is supposed to have lived in Montreal in 1844. Any information will be received with thanks.

Box 523, Houston, Texas. HENRY MALMGREN

CANADIAN SOCIETY OF CIVIL ENGINEERS.

The fourteenth annual meeting of the Canadian Society of Civil Engineers opened in the society's rooms, Montreal, on the 31st inst., the president, W. T. Jennings, in the chair. There was a large attendance of members.

The various committees presented their reports, and all the regular business of the convention was concluded on this day, except the reports of the scrutineers on the election of members of the council. The elections for the chief offices resulted as follows: President, Prof. H. T. Bovey; vice-president, C. H. Duggan, Percival W. St. George and E. H. Keating; treasurer, H. Irwin; secretary, C. H. McLeod; librarian, E. Rhys-Roberts. It was agreed that the report on the election of the members of council should be presented at a meeting to be held on the 8th February.

The following were elected as nominating committee for the ensuing year: For Quebec—L. G. Papineau, C. le B. Leprohon. For Ontario—C. H. Rust, J. Galbraith, G. A. Mountain. For Manitoba and N.W.T.—Col. H. N. Ruttan. For Maritime Provinces—Dr. Martin Murphy. For Newfoundland and Foreign—L. Skaife. On motion of W. J. Sproule, seconded by L. S. Pariseau, Duncan Macpherson and T. Harry Jones, it was decided to devote $200 to the Patriotic Fund. The resolution was followed by "God Save the Queen."

The meeting adjourned at 6.30 p.m., and the members took a special train for Boston, the train being provided by courtesy of the Grand Trunk Railway. A report of the meeting and an account of the excursion and dinner at Boston will appear in next issue.

SCHOOL HEATING AND VENTILATING.

The question of heating and ventilating school buildings is a most important one in Canada, owing to the length of our "closed-in" season. The various systems now in use were criticized in The Canadian Engineer some months ago, when the report of the Toronto Board of Health on the subject of school ventilation was dealt with. The chief engineer to the Board of Education of Boston, Mass., T. J. Waters, in a report on school ventilation in Boston, made to F. W. Chandler, professor of architecture, Massachusetts Institute of Technology, takes up the following, the chief points of which were printed in the City Record, Vol. III., No. 1, which is an official publication of the city of Boston:

(1) It has been my practice to install furnaces in all buildings containing six rooms and under, although I have placed low pressure gravity steam-heating apparatus in some buildings containing but four class-rooms. The small buildings in which furnaces are installed are of a temporary character, and constructed of wood in the outlying districts. (2) The cost of heating and ventilating apparatus of two school buildings, each containing eight class-rooms, and an assembly hall, the equivalent of two class-rooms, erected in 1894, is as follows:

Steam heating and mechanical ventilating apparatus.... $5,188
Furnace heat and natural ventilation..... 3,200

(3) The amount of coal and cost of same for each building for a period of two years follows: Steam-heated building—
1896-97, 372,710 pounds bituminous coal, at $2.30 per ton.$428 61
1897-98, 410,175 pounds bituminous coal, at $2.05 per ton. 451 18

Furnace-heated building—
1896-97, 393,435 pounds anthracite coal, at $5.60 per ton.$1,101 61
1897-98, 297,250 pounds anthracite coal, at $5.72 per ton. 850 14

(4) Repairs to apparatus from 1894 up to date: Steam-heated buildings, $84.62; furnace-heated building, $454.35. (5) A steam-heating apparatus, such as I now design, will certainly last twenty-five or thirty years. I know of a school building in Chicago which was equipped with a steam heating apparatus in 1856, and the wall coils, which extend around the class-rooms under the windows, are still in position and doing service. The boiler I removed about six or seven years ago, as it was inadequate to generate sufficient steam for additional heating surface which was placed in the building. Now, with regard to furnaces, I wish to state that the life of a fire pot is rarely over two years. Of course, when a defective fire pot is removed and a new one substituted, the furnace is practically as good as new. The large cast iron tubular furnaces give better results, but the large arch plates are liable to crack at any time, thus allowing smoke and gases to pass up into the rooms with the incoming air. During the past ten years furnaces were removed from thirty-six school buildings in the city of Chicago, with an average of about fifteen class-rooms each, and steam-heating and mechanical ventilating apparatus substituted. The Board of Education of the city of Chicago has not installed furnaces in any first-class school-building for the past sixteen years, except the one referred to in this communication, which is an addition to an existing building, the same being heated by furnaces, and the character of the old building was such that the introduction of modern steam-heating and ventilating plant to heat both buildings was not permissible.

THE MARINE ENGINEERS.

The first meeting of the Grand Council of the National Association of Marine Engineers of Canada, took place recently, at the Albion Hotel. The object of the association, which is intended to include all the marine engineers from the Atlantic to the Pacific, is to promote the interests of the engineers, to advance the standards, and see that none but those duly qualified according to law be employed in that capacity. Its intention is thus to protect passengers and the property of the steamship companies from all risks.

Several questions of interest to the calling were discussed, and the following officers were appointed: Grand president, D. L. Foley, Toronto; grand vice-president, Wm. I. Barton, St. John, N.B.; grand secretary-treasurer, S. A. Mills, chief engineer, Toronto Ferry Co., Toronto; grand conductor, Jas. A. McCarthy, Montreal; grand auditors, J. Fred. Williamson and G. T. G. Blewett, St. John, N.B. The constitution which will govern the society was adopted, and the meeting went on to discuss the bylaws. The next annual meeting will be held at St. John, N.B., in January, 1901.

LITERARY NOTES.

British Policy in South Africa. By Spenser Wilkinson. Publishers, Sampson Low, Marston & Co., London. One shilling.

Paul Kruger: His Life Story. By Fred. A. Mackenzie. Publisher, James Bowden, 10 Henrietta street, London. Illustrated. one shilling.

An illustrated catalogue describing the new McEwen gas engine will be issued in a day or two by the Waterous Engine Works Co., Brantford, Ont.

The Transvaal Trouble; How it Arose, being an abstract of the biography of the late Sir Bartle Frere. By John Martineau. Publisher, John Murray, Albemarle street, London. One shilling

The History of the Great Boer Trek and the Origin of the South African Republics. By the late Hon. Henry Cloete, Her Majesty's Commissioner for Natal, 1843-4; edited by his grandson, W. B. Cloete. Publisher, John Murray, Albemarle street, London. One shilling.

The Blacksmith and Wheelwright sends out a most attractive special number, which commemorates the twentieth anniversary of its establishment. An interesting feature of the issue is the announcement of the "20-year advertisers," as those are called who have occupied space in the Blacksmith and Wheelwright for that length of time.

The Mechanics' Supply Co., Quebec, has sent out this year the daintiest New Year souvenir that we have seen. It is a delft blue covered folder, tied with white ribbon, bearing on the front cover the words, "Greeting, 1899-1900." Inside, some apt quotations are followed by a couple of pages referring to the position and goods of this well-known company.

A great deal of attention is now directed to the Topeka Capital, a Kansas daily, which is to be placed absolutely at the disposal of C. M. Sheldon, author of "In His Steps," etc., that he may show what a Christian daily newspaper ought to be. If the experiment is continued long enough it is certain to succeed, because Canada has had for over sixty years a journal which has been consistently conducted upon this plan. It is The Daily Witness, Montreal.

"Machine Shop Companion," by Wallace Bentley, A.M.I. Mech.E., consulting mechanical engineer, Halifax, Eng., author

of "Sketches of Engine and Machine Details," etc. This book, which has thirty-six illustrations, is specially written for practical Engineers and Mechanics. It is bound in flexible cloth covers, suitable for the pocket, and is full of useful notes, rules, and tables for everyday workshop use, it shows in a simple way how to calculate speeds of pulleys, cones, wheels, etc., and includes an illustrated chapter on "Screw-Cutting," with list of Change Wheels, Notes on the Lathe, Drilling, Planing, Shaping, Slotting, Milling and Gear Cutting Machines; Notes on Materials, Forging and Welding, Hardening and Tempering, Case-Hardening, Templates, Gauges, Tables of Whitworth's Standard Screws, Taps, etc. The Bentley Publishing Co., Crossley street, Halifax, England.

"The First Night of a Play," "Through the Slums with Mrs. Ballington Booth," "What it Means to be a Librarian," by Herbert Putnam, Librarian of Congress, and "The Pew and the Man in it," by Ian Maclaren, are among the notable features of the February Ladies' Home Journal. An American Mother answers conclusively "Have Women Robbed Men of Their Religion?" and there is an interesting article on Mlle. Chaminade, the famous composer and pianist. Another article describes "Frank Stockton's New Home in West Virginia." The opening chapters of "The Parson's Butterfly," a new serial by Mrs. Charles Terry Collins, are also presented. Molly Donahue discusses woman's rights with Mr. Dooley, and "Edith and I in Paris," "Her Boston Experiences," and "The Autobiography of a Girl!" continue with increasing interest. The pictorial feature, "In Honor of St. Valentine," by Alice Barber Stephens, will recall some happy bygone days. By The Curtis Publishing Company, Philadelphia. One dollar a year; ten cents a copy.

No subject of interest to citizens of the British Empire in common has been so befogged with half-truths and with misrepresentations as the South African question. It is now generally known that besides the London edition of The Standard and Digger's News, controlled by the Transvaal Government, the Boers had—and in some cases still continue to have—subsidized newspapers on the continent and in the United States, which published and reiterated the most distorted and untruthful statements of affairs in the Transvaal. As many of these travesties of history originated as official statements from the Transvaal Government itself, and as British readers are apt to credit any other Government with the same respect for truth in official documents as would characterize their own Government, the Boer official falsehoods had been so widely and industriously circulated that when the war cloud burst a great proportion of people were in a mist as to the real facts of the case. The series of articles which have been appearing in this journal (now reprinted in pamphlet form under the title of the "Boer War") may have helped to dispel these mists from the minds of Canadian readers, but we are glad to call attention to the cheap and handy volumes above quoted, as further contributions to the literature of the subject, which will enlighten the Canadian reader still further on many points. The first named summary of the recently published biography of Sir Bartle Frere turns the search-light on the dealings of the Gladstone Government in South Africa at the time of the retrocession of the Transvaal to the tender mercies of the Boers. Leaving out of view Sir Alfred Milner, the present governor of the Cape and High Commissioner for South Africa, whose work is not yet accomplished, there have been in the history of colonial administration there three great governors, who understood and wisely estimated the problems of British relations with both the Dutch and the natives. These were first, Sir Benjamin Durban (whose mortal remains rest in the old Papineau Road military burying-ground in Montreal), Sir George Grey and Sir Bartle Frere. If the policy of the first two governors had not been thwarted by the Home Government, who sent them out, there would have been no Republic of the Orange Free State or the Transvaal to prove the thorns in the flesh of the rest of South Africa which they have; and if the policy of the last named had not been similarly thwarted even these separated communities would have been reconciled to the neighboring colonies, and we should have had a peacefully confederated South Africa to-day. One cannot rise from a perusal of "The Transvaal Trouble" without the feeling that Sir Bartle Frere was basely betrayed in his efforts to carry out his great aims, not only by the Gladstone Government, but by the Conservative opposition of that day, who selfishly sacrificed the higher interests of empire for party advantage in home politics. In the light of present events Sir Bartle Frere's estimate of the men with whom he was dealing from 1877 to 1880, and his judgment of the effects of the political movements then transpiring shows him to have been a man of extraordinary wisdom and foresight, and his predictions of what would happen if such and such a policy were carried out read now like pages of inspired prophecy. The statement in one of his letters that his administration would add another to the list of those whose teachings and work were not understood or appreciated till he was dead and gone, was itself a prophecy and has received its fulfilment in a way that must bring the blush of shame to some public men still sitting in the House of Commons, who deserted him in the hour of his trial. The memory of no governor in South Africa is to-day in higher regard, both among British and Boer, and if the British Government had only stood by him there would have been a confederation instead of a war there to-day. The "History of the Great Boer Trek" is a series of re-edited lectures on the motives of the great treks which led to the founding of the Free State and Transvaal, and in part to the colonization of Natal. The author, a loyal British subject of Dutch descent, treats the Boer's sentiments with natural sympathy, and shows us how they regarded the emancipation of the slaves in 1834-7, and how the blunders of governors combined with the vacillation of the British Government to produce that distrust and suspicion which are the regrettable national weakness of the South African Dutch, and which unfortunately have only been confirmed by the policy of the Gladstone and other recent British administrations. Mr. Wilkinson in his "British Policy in South Africa," takes up the question from the British and Imperial standpoint, but shows none the less clearly from this point, that party politics at home have been the curse of British rule in these colonies. Though this book was written before the war broke out Mr. Wilkinson saw that if Britain failed to maintain her position as paramount power or deserted the cause of the Uitlanders the Afrikander Bond would agitate for the independence of South Africa and British subjects, feeling deserted by their own Government, would make common cause with the members of the Bond. The loss of South Africa could then be only a question of a short time. Mr. Mackenzie's little book gives us a sort of crayon sketch of Paul Kruger, and avoiding politics as much as he can, desires to show us the man himself. He gives the old man credit for great virtues, but does not by any means hide his great faults. The result is a readable book, which has a number of half-tone illustrations. To those who wish more light on a subject of such vital interest to the future of the British Empire we can commend all of the above books.

AUTOMOBILE NOTES.

The whole of the Russian Imperial family, excepting the Czar, are enthusiastic chauffeurs.

The traction engines in use by the British army in South Africa do not seem to be very successful, according to some accounts.

In Algeria steam omnibuses are doing good work, and it is expected that they will be employed very largely in Madagascar.

There is scarcely anyone connected with the cycle and carriage building trades in France who is not interested more or less in the autocar industry.

A French count was sentenced to two months' imprisonment and fined $1,500 for breaking a lady's leg through his careless driving in the Bois de Boulogne.

The Stirling Motor Carriages, Ltd., of Hamilton, Scotland, has paid a five per cent dividend, and written $75,000 off goodwill account, as the result of last year's business.

The autocar as a delivery agency for newspapers in long, straggling country districts should prove invaluable. Two of the London Sunday journals have tried it with great success.

The Automobile Club of France has a membership of 2,000, a yearly income of $80,000, and the finest clubhouse in the world. Similar clubs have been formed in Berlin, Brussels, London, Turin, Geneva, London and New York.

A steam postal van has been sent to Ceylon from the Lancashire Steam Motor Co., of Leyland, England. It will carry a ton of mail matter in bags, and will make an average speed of ten miles an hour on ordinary country roads.

The Velo states that in France during December there were 708 accidents—52 deaths and 656 injuries—due to horses, and only 21 automobile accidents (causing one death) in the same period. There are about 4,000 automobiles running in France.

"Inshaw's Steam Wagon," or lorry, is running in Birmingham, made by the son of the worthy machinist of that name, whose early production of a steam carriage was illustrated in The Canadian Engineer last year from a photograph obtained from another member of the family.

The Municipal Council of Paris, France, has reduced autocar speed to 12 kiloms. in the Bois de Boulogne. The French correspondent of the Autocar suggests that the authorities should take in hand the task of regulating the horse traffic, and thus remove the chief source of danger to the automobilist.

The Motor Trades' Association has been organized in England "to afford mutual protection to its members, and to promote such measures as may be found useful in the interest of the motor industry in the United Kingdom, including the encouragement of invention, regulation of prices, and arrangement of shows."

The Autocar, of London, England, says everything points to a big motor year during the next twelve months, most of the manufacturing houses having experienced no "dead season" this year, as they have sufficient orders to keep them fairly busy all winter. One firm sold four motor cars in one week. The position of the autocar to-day is immensely superior to what it was twelve months ago.

Belgium, Germany and the United States will contest with the French champions for the Gordon-Bennett cup. It is reported that Mr. Riker and Mr. Winton have offered to represent the American Club, and that the former is having an electric car built specially for the race, which will be over a course of 125 kiloms. M. A. Lemaitre is having a 100 h.p. car with 8 cylinders built for this race.

The British Motor Car Club offer eight cash prizes, four of £100 each and four of £50 each, for the following inventions: An exhaust deodorizer, an automatic starter, the best ignition, and the simplest and cheapest design of motor and car complete. The winners of the prizes will retain to the full their interest in the inventions, which the club will assist them to get properly patented throughout the world.

A correspondent of the Autocar suggests "power-vehicle" as a comprehensive generic name for automobiles, while classes would be named "power-carriages," "power-carts," "power-wagons," and these again would divide up into sub-classes, as "power-landau," "power-victoria," etc. He objects to "motor," because of the many confusing senses in which it can be used. By the way, "Steamobile" appears in the Automotor journal.

The makers of steam carriages in the United States have struck a snag in a law which requires that anyone operating a steam road engine must be an expert engineer and be properly certificated. The Locomobile Co., who manufacture the Stanley steam carriage, are trying to get the regulations modified to allow the issue of "third or fourth class" certificates to owners of steam cars, who show themselves proficient in their use.

The Automobile Club of England is organizing a 1,000 miles efficiency trial, with the full approval of automobile manufacturers of Great Britain. The London Daily Mail has voluntarily offered prizes of $500 for the first, $250 for the second car coming through the trials best, and in addition, $50 to each car successfully accomplishing the journey. This club has been asked to officially take charge of the English automobile section of the Paris Exhibition.

The Autocar has made a careful calculation and reports that during 1899 very close on 2,000 automobiles of various kinds were made in or imported into Great Britain—this number being about equally divided between autocars and various descriptions of motor cycles. The trade in 1900 is likely to be increased at least 50 per cent. most probably doubled. The demand will be higher than this, but the ability to supply will affect the total at end of year.

The Autocar urges the British War authorities to investigate autocars as the German military man and the Emperor did, to their great satisfaction, the cars having carried weights up to 2¼ tons over bad roads, up hills, across stony and sandy track, and even on loose ploughed lands, and finally two baggage and two passenger wagons, heavily laden, satisfactorily competed with the Brocken railway in crossing the Brocken. The Emperor highly praised the performance.

The Chinese ambassador visited Coventry, Eng., in December, was met at the station by a fleet of motor cars, and after inspecting the factories made a speech in which he said: "The services rendered by the motor car to the field gun in time of war, as well as to the collection and distribution of mails in time of peace, are simply invaluable, and I have no doubt that when all our roads in China are restored these vehicles will be introduced into the far East, as well as they are now introduced into the West."

Here is an item from the Horseless Age of New York: "The Canadian Government has been experimenting for some time with various motive powers as a propelling force for mowers, reapers and other agricultural machinery. The tests have been made at Montreal, and one of the most recent was the driving of a gang plough by a gasolene motor, built by the Haynes-Apperson Co., Kokomo, Ind. It is said the motors will be attached to other farm machinery and produced in quantities."

H. Wilcke has written a pamphlet on "The Haulage of Goods on Common Roads," in which he shows that cheap production necessarily involves cheap transport; that British railways have made competition with other countries a difficult matter, instead of helping the producer; that within at least forty miles radius all transporting of goods can be done quicker and cheaper by self-propelled vehicles on common roads than by railways, and that all works on farms, no matter where, may thus have the equivalent of a railway siding.

New York has a new motor—not adaptable yet to carriages, but likely to develop on that line. It is called the "Secor," uses kerosene or heavy oil, feeding oil and air in chemically correct proportions straight into the cylinder, exploding by electric spark. It has neither oil pump nor vaporizer, exhaust invisible and almost odorless, while the motor runs 300 or 400 revolutions a minute, and governs so perfectly as to be able to drive a dynamo for variable electric lighting without going more than one volt out of the way—which is as good as steam engine performance.

The power required for motor vehicles may be gathered from the following figures showing tractive resistance, pounds per ton—ordinary metal tires and plain bearings being used: Railroads, 10; tramways, 30; good asphalt, 13, asphalt, 22; poor asphalt, 29; wood paving, 30; good setts, 35; best macadam, 42 to 46; good macadam, 50; ordinary macadam, 60 to 80; soft macadam, 97; best gravel, 57; cobbles, 60; ordinary cobbles, 130; very bad cobbles, 240; best clay, 110; hard dry clay, 100; sand road, 360; loose sand, 560. The authorities for above figures are Telford, Whyte-Smith, United States Agricultural Bureau, and Society of Arts.

A striking illustration of the unfairness of the British law limiting the speed of autocars to 12 miles per hour is shown by examining the time-table of the Tally-Ho Independent stage-coach, which ran between London and Birmingham in 1830. The distance, 100 miles, was covered in 7½ hours, the average speed, allowing for changes of horses, being over 13 miles per hour, and the actual speeds being as follows for the seven sections into which the trip was divided: 16.17, 18.75, 11.85, 14.64, 12.45, 16.50, 14.50. Only in one case is the speed below the autocar limit; yet this was in the days when the main highways were carrying their maximum of traffic, and were the only means of intercommunication, except canals.

Jenatzy, the famous French chauffeur, has driven his torpedo-shaped car, the "Jamais Contente" (never content), for one kilom. at the rate of 106 kiloms. an hour, and offers to bet $20,000 that he can drive it 100 kilom. in sixty minutes. The bet will likely be taken up by sporting men, and Jenatzy will risk this tremendous stake, as well as his life, on the result. The car would have to carry about two and a half tons of batteries, and this enormous weight added to the friction in flying over the

roads at such a rate, would, it is feared, very soon tear the tires to pieces. It would be interesting to calculate the force exerted by a four-ton vehicle at this speed in the event of meeting with an obstacle—a contingency not at all impossible.

Mr. Pennington, to whom The Canadian Engineer in its earlier days paid its compliments, is to the fore again in a characteristic exploitation. He seems to have joined forces with the equally well-known H. J. Lawson, of British Motor Co. fame. It appears that a company called the Anglo-American Rapid Vehicle Co., has been registered under the laws of the State of Delaware, the nominal capital being $75,000,000, and the working capital $10,000,000. It is understood that this company will take over the whole of the Pennington rights, both in Britain and abroad, as well as a considerable interest in the patents held by the British Motor Co., that it will also secure the Daimler patents for the United States, and organize for business throughout the world.

The weekly Horseless Age, of New York, devoted its issue of December 6th to steam, and that of January 17th to explosive motors. Some of the articles in the steam number were: Steam Boilers for Motor Vehicles, General Data on Steam and Fuel, Shell or Water Tube Boilers? Boiler Feeding Apparatus, A Practical Method of Utilizing Exhaust Steam, The Elihu Thomson Flash Boiler and Steam Vehicle System. Jas. A. Wright, of Montreal, wrote, strongly commending this issue, and giving his opinion that steam would find its most perfect expression through American work. The Explosive number contained articles on the Hydrocarbon Engine as a Source of Energy, Gasolene Engine Indicator Diagram, Ignition and Ignition Troubles, Vaporizers and Carburetters, Coils and Sparks, Vibration, Gasolene and Gasolene Mixtures, Multi-Cylinder Engines, Explosive Motor Data and Details. A correspondent of The Age objects to the term "Explosive Motor," saying, "An explosion does not occur in a gas engine; therefore it is wrong in principle to call it an explosive engine."

Hugh Dolnar, the able American correspondent of the Autocar, cleverly summarizes the situation in the United States thus: "Winton and Charron did not make a match, Davis and wife by dint of hard work and constant repairs of their 'National' wagon finally reached Chicago and stopped there instead of pushing on to San Francisco, the Walker $2,000 prize run was called off, and there has really been no clean cut and well defined item of autocar advancement in the United States the whole summer through. There have been charters granted, with vast nominal capitalizations, to many new companies, but when one goes out to look for the new and altogether satisfactory wagon he simply does not find it. It is pretty well understood that compressed air has something to talk about and nothing to show. The liquid air schemes, as all even tolerably well informed mechanics are aware, have not a ghost of a chance until somebody finds out something no one knows yet. The Stanley steam wagon has been delivered to many purchasers, and has given plenty of trouble to those who have tried to use it, in the way of scorched boilers and small water tank room. If a steam wagon is to be really popular it must condense its steam, and it must carry its water automatically: these two prime necessities are imperative demands, and cannot possibly be ignored. But underneath all of this seeming stagnation in automobile matters there is a fierce and stubborn contest going on between, perhaps, as many as 500 American inventors and the reluctant forces of nature. Everyone of these experimenters has set up a high standard of excellence, and is keeping well under cover, waiting the day of triumph before giving out anything to the public. We have come to pretty fully and clearly understand the severe exactions of the motor problem, and some of the Yankee mechanics will find good answer to the riddle, you may be sure of that."

—In the December issue of The Canadian Engineer an article on "Tall Buildings Under the Test of Fire," by H. De B. Parsons, was published. This article was written originally for The Engineering Magazine, but was republished in the reports of the British Fire Prevention Committee.

—Canadian trade in Australia increased between 1896 and 1898 at the rate of more than three hundred per cent.

Industrial Notes.

Tadoussac, Que., is to have a system of waterworks next year.

The Berlin, Ont., waterworks earned $5,000 for the town last year.

The Abbott-Mitchell rolling mills at Belleville, Ont., are now in operation.

The O. W. Thums Co. is starting a factory at Walkerville, Ont., for the manufacture of fly paper.

A new bridge is proposed over the Castor River between Carleton county and Prescott and Russell.

The new glass factory at Kingsville, Ont., started up the first week in January, using natural gas as fuel.

Five new buildings are being erected at Granby, Que., in connection with the Granby enamelware works.

Moose Jaw, Assa., is discussing the raising of $75,000 to be spent in local improvements of a permanent sort.

The W. W. Ogilvie Co. is applying for incorporation to carry on the flour milling business of the late W. W. Ogilvie.

The Shawenegan Falls Hotel Co. is being incorporated to build a $25,000 hotel at Shawenegan Falls, Que. B. Shepherd, manager.

The Hamilton Iron and Steel Company, Hamilton, has just put in a new boiler which was supplied by the Goldie & McCulloch Co., Ltd., Galt, Ont.

J. McCrois' new foundry at Lindsay is nearly completed It is 35 x 68 feet, and two stories high. A second building, 45 x 45 feet will be put up in the spring.

The Bain Wagon Co., Woodstock, Ont., has built for the Department of Militia sixteen special wagons, which are being sent out with the Second Contingent.

The ratepayers of Cookshire, Que., have voted a $15,000 bonus to the Canada Food Supply Co., and it is expected that the company will start its cannery building at once.

The Goldie Milling Co., Highgate, Ont., has put in a Moffatt Feed Water heater. The Goldie & McCulloch Co., Ltd., Galt, Ont., is sole Canadian maker of this heater.

Mrs. Doran, of North Bay, widow of Judge Doran, formerly of Perth, Ont., has sold a water power on the Spanish River, near Webbwood, Ont., for $12,000, to a pulp syndicate.

The St. Charles Condensing Co., Ingersoll, Ont., has received some heavy special machinery from the Goldie & McCulloch Co., Ltd., Galt, Ont., for the new condensing works.

The Smart-Eby Machine Co., Ltd., Hamilton, Ont., is turning out a 75-ton refrigerating plant for a large brewery. The plant is modeled on the Buffalo Refrigerating Co.'s plans.

An elevator and flour mill company has been formed at Morinville, Alberta, under the title La Compagnie d'Elevateur et de Moulin a Farine de Morinville. The capital is $15,000.

The Walkerville, Ont., Match Co., promoted by Peter Stenius will have their new match factory running some time in March. A large part of the machinery comes from Sweden.

The present output of the Nova Scotia Steel Company is about 100 tons of steel per day. Seven hundred men are employed at the company's works at Trenton and Ferrona, N.S.

Work at the Maritime Clay Works, Pugwash, N.B., will be resumed shortly, it is said. A continuous kiln for burning brick is to be built, and it is said will take 450,000 bricks to build it.

A great deal of activity is evident at the charcoal iron plants at Radnor, Que., operated by the Canada Iron Furnace Co., and also at the Drummondville furnaces worked by the McDougall estate.

The Paisley, Ont., Pork Packing Company, Ltd., recently organized there, with a subscribed capital of $10,000, has bought the old Northern Hotel property, and intends fitting it up immediately.

J. Oliver & Sons, Ltd. has been incorporated to manufacture and deal in furniture in Ottawa, Ont., and carry on the business now being done by Jos. Oliver & Sons; the capital of the company is $90,000.

The Canadian Food Supply Co., Montreal, is being incorporated with $50,000 capital, to can meat, vegetables, etc. W. Pendy, J. Lawson, A. Dunlop, E. Bailey and S. Jamieson are the provisional directors.

The Keewatin Lumber and Manufacturing Company, Keewatin, Ont., is building a mill dam and putting in a new and larger water wheel. Before spring one of the circular saws will be replaced with a band saw.

The very large quarries at Marble Mountain, N.S., have been bought by the Dominion Iron and Steel Company. Quarrying operations will begin at once and shipments will be made over the I.C.R. to Sydney, C.B.

Tenders for the steel or wooden bridge across the Thompson River at Kamloops, B.C., will be received up to February 28th. Plans are at the Lands and Works office, Victoria, B.C. W. S. Gore is deputy commissioner.

A. Roy is to establish a foundry at Toronto Junction. The town grants a site at a nominal price and Mr. Roy undertakes to put up a brick building, 100 x 50 feet, to be completed by June 1st, and to employ at least five men.

Application for incorporation is being made by the Stuart-Arbuthnot Machinery Company, Ltd., to take over the business of Stuart & Harper, machinery, Winnipeg. John Arbuthnot, lumber dealer, is a new member of the firm.

A company has asked for incorporation to own and operate a threshing and flour mill and a lumber mill at Beaumont, Alberta. The name of the company is Le Compagnie des Moulins de Beaumont, and the capital is $4,000.

It has been announced in Toronto that the Heinz Pickle Mnfg. Co. would at once establish its proposed Canadian factories in Toronto. The company has started a European trade, and the English market will be supplied from Canada.

The new Maria street bridge, Ottawa, will have two stone piers and two stone abutments. There will also be about twenty little foundation piers, on which will rest the end of the iron pillars that will support the structure over the railroad tracks.

The Goldie & McCulloch Co., Ltd., Galt, Ont., has shipped a high-speed Ideal engine to Sarnia, Ont., for the Canadian General Electric Co., of Toronto. The Montreal Rolling Mills Co. recently purchased one of these engines from the same company.

J. E. Murphy, Amabel; R. P. Butchart, Keppel; G. S. Kilbourne, J. Lucas, J. M. Kilbourne and D. M. Butchart, Owen Sound, Ont., have been incorporated as the Shallow Lake Portland Cement Co., Ltd.; capital, $199,000; chief place of business, Owen Sound.

Redpath-Reid automatic smoke consumers have recently been supplied by the Jubilee Grate Bar Co., Ltd., to McClary Mnfg. Co., London, Ont.; Canada Screw Co., Hamilton; Beaver Mnfg. Co., Hamilton; Lyman Bros. Co., Toronto; Sanford Mnfg. Co., Hamilton.

The Gyrator System of Flour Milling, of which the Goldie & McCulloch Co. is sole Canadian maker, is meeting with great success in the milling world. The company has recently shipped a car-load of this kind of machinery to the Farmers' Milling Co., Fort Saskatchewan, N.W.T.

La Compagnie de Pulpe de Jonquiere is applying for legislation to enable it to expropriate lands on Riviere aux Sables and on Lake Kinogami in the county of Chicoutimi, Que., and develop the water power of the Riviere aux Sables, throughout its entire length, and to build pulp mills.

The Halifax Herald stated recently that a new wing and pattern shop have been added to the Cape Breton Foundry and Machine Co., Sydney, C.B. The St. John brass founders, T. McAvity & Sons, who have large contracts with the Dominion Iron and Steel Co., are preparing to erect a branch foundry at Sydney.

The following application to the Ontario Government for power to issue bonds are made: Meaford, $56,000, to bonus the Botsford Jenks Co., of Port Huron, Mich., and the G. T. R. elevator; Dunnville, $10,000, to bonus F. R. Lalor in establishing a tanning factory; Port Perry, $5,000, to aid a House of Refuge and Industrial farm for the county of Ontario; Port Hope, $20,000, to enlarge the waterworks.

The Ironsides Mining Company, Ltd.; capital, $100,000; headquarters, Ottawa, is being incorporated to develop iron mines near Ottawa city. The provisional directors are: W. L. Holmes, Detroit; J. L. Robertson, W. R. Hinsdale, New York; J. O. Hibbard, C. B. Hibbard, D'Arcy Scott and W. H. Curle, Ottawa.

R. F. Prefontaine, Q.C., Montreal; J. A. C. Madore, Q.C., A. R. Angers, O. Rolland, J. L. Decarie, A. Beauvais, J. L. Warren, M.D., J. A. Drouin, Montreal; P. V. Savard, Chicoutimi, and J. Warren, Pointe a Pic, are being incorporated as the Great Northern Elevator Co., to build elevators in Quebec city and elsewhere.

The Weymouth, N.S., mill of the Sissiboo Pulp and Paper Co. is now turning out 300 tons of dry pulp per month. New machinery is being added and preparations are under way for building a new dam and a large mill in the spring, for which machinery is now being contracted for. The new plant will be in operation by November 1st next.

The North River Lumber and Pulp Company, Ltd., is being incorporated, with a total capital stock of $50,000; headquarters at Valmorin, Que.; to carry on the manufacture of pulp, paper, etc. The following are the names of the petitioners: C. R. Burleigh, Whitehall, N.Y.; G. W. Macdougall, Wm. J. Henderson, A. R. Macmaster and H. McKay, Montreal.

A circular issued by the G.T.R. announces that the special rates on pulp wood out of Canada to points in the United States have been withdrawn, and the regular tariff at a much higher rate has gone into effect. This has been done, it is said, to help encourage the manufacturers of pulp and paper in Canada. The low rates on pulp wood to and from local points will continue the same as before.

Canada is gradually taking her place among countries who can manufacture for the world. Last autumn the Goldie & McCulloch Co., of Galt, shipped to Mexico two car-loads of bagasse filters to be erected on Mexican sugar plantations, and each season the same company exports to Cuba several thousand dollars worth of sugar machinery. Before the Boer war they also shipped mill machinery to Lorenzo Marques, in Portuguese South Africa.

J. L. Jennison, one of the directors of the New Glasgow Milling Company, recently stated that the company proposes to build mills at St. John, N.B., and Halifax, N.S., in addition to that at New Glasgow. They have obtained a new charter from the Dominion Government granting them more extensive rights than the local charter under which they have been working. The name of the company has been changed to the Maritime Milling Company.

The B. Greening Wire Co., Hamilton, Ont., has now completed the issue of all the catalogues of perforated metals, wire cloth and screens of all widths, sizes and grades, wire rope, steel or iron wire, window guards, flower stands, counter railings, foundry supplies, etc., handled by the company. To mail any of these catalogues to interested parties will be a pleasure to the company, if they will state which department they are interested in.

The American School of Correspondence, Boston, Mass., is now exceeding its operations in Canada. A folder recently issued repeats what a number of Canadians write about this school. Among those who have examined the literature and examination papers of the school, and certified to their value, are H. T. Bovey, LL.D., M.I.C.E., F.R.Sc., McGill University; J. Galbraith, principal of School of Practical Science, Toronto, and a large number of others.

About 150 couples, among whom were many prominent labor advocates, attended the annual concert and "At Home" of Toronto Branch No. 46 of the Plumbers', Steam and Gasfitters' Association, held January 26th, in the Confederation Life Building, Toronto. Mr. Robert Harrison presided at the concert. The program was contributed to by Messrs. W. Street, A. Parker, H. Bates, W. White, F. Hancock Matthews, J. Dempster, F. Wray and Master Owens. During the concert the handsome silver cup donated by the Toronto Letter-Carriers for the best appearance of any one union organization in the Labor Day parade, and which was awarded to this union, was handed over to the victors.

A deputation, of which E. F. B. Johnston, Q.C., was spokesman, waited on Hon. E. J. Davis last month, and asked a concession from the Ontario Government of certain lands on the Montreal river, which flows into Lake Temiscamingue. The syndicate proposes to expend $100,000 on a plant, and agrees to employ 25 men during the first year. Those interested are: W. C. Phillips, Dr. Lynd, P. McArthur, R. Davies, W. R. White, W. Kerr, John Gray, A. Niven, John Ferguson and E. F. B. Johnstone.

The Dowd Milling Co., Ltd., is applying for incorporation; capital, $100,000; headquarters, Quyon, Que., to mill oatmeal, flour, etc. The following are the applicants: H. S. Dowd, Quyon; B. W. Dunnett, Pakenham, Ont.; J. A. Cameron, Dominionville, Ont.; G. T. Mohr, J. Amm, Quyon; J. Pritchard, North Wakefield, Que.; D. B. Maclaren, Fitzroy, Ont.; R. H. Sayer, Aylmer, Que.; E. Graham, Bristol, Que.; W. H. Meredith, Quyon; G. Walsh, Onslow, Que.; C. Brooks, Quyon, and W. Harrison, Quyon.

Some time ago the boiler in the Crescent Milling Company's factory, London, Ont., exploded, wrecking the brick engine-house, but not damaging the factory close by. The force of the explosion moved the boiler about fifty feet. Fragments of the engine-house were afterwards found two hundred feet away. J. Hetherington was the only man in the engine-house at the time. He was seriously scalded about the head and shoulders, but was not fatally hurt. The cause of the explosion is said to have been the giving way of a patch in the end of the boiler.

It is stated from Quebec that a new proposition for the establishment of refrigerators and abattoirs in the district of Quebec is to be made shortly to the Provincial Government by various tenderers for its consideration before the coming session. The proposal contemplates a fixed subsidy not exceeding $30,000 a year for a certain period, instead of the previously proposed guarantee of 3 per cent. on $1,000,000, not to be paid till the business has been established, and some $500,000 spent on buildings and plant.

A special train took 500 laborers from Boston, U.S., for Sydney, C.B., recently. They will be employed on the construction of the large plant of the Dominion Iron and Steel Company, Ltd. Workmen of all kinds, from all parts of the country, are going to Sydney, where an opportunity for employment awaits most who apply. It is expected that within six months from two to three thousand workmen will be employed upon the plant in the capacity of carpenters, blacksmiths, steamfitters, plumbers and ordinary laborers. In all cases those who have gone have paid their own railway fares.

Justice Rose, Toronto, has granted an order to wind up the business of the Canadian Locomotive and Engine Company of Kingston, and appointed A. F. Riddell, of Montreal, accountant, as provisional liquidator. The application was made on behalf of James W. Pyke, of Montreal, a creditor, and the order was consented to by the Bank of Montreal, who are the heaviest creditors of the company, which admitted its insolvency. A meeting of creditors, shareholders and contributories will be held at Kingston on Feb. 10, when the question of the appointment of a permanent liquidator and other matters will be decided upon.

The Canada Paint Co., Ltd., Montreal, Toronto and Victoria sent out a circular at the end of last month stating that the price of the best paints, such as the "Elephant," "Prism" and "Stag" brands had been advanced to $1.20; their extra grade floor paints to $1.10, and their standard grades to $1 per gal. The reason given for these advances is the rise in the price of turpentine, oil, lead, zinc and tin cans. Since "Elephant" paints were $1 lead has advanced 2c. per lb., zinc 1½c. per lb., linseed oil 18c. per gal., turpentine 20c. per gal., and tin cans average an advance of 4c. per gal. This advance is said to be equivalent to 28c. per gal.

The Ontario Association of Architects held its annual meeting, January 16—19th in Toronto. The business proceedings have to a great extent centered on the resolution to establish themselves in a headquarters on King street, with a suite of rooms suitable for the usual meeting of the society, and for classes, sketch clubs and other assistance to the education of students, which it is desirable to establish. The new council of the association are: President, A. Frank Wickson; first vice-president, Fred Henry, London; second vice-president, Grant Helliwell; treasurer, F. S. Baker; council, G. E. Belcher (Peterborough), S. H. Townsend, W. A. Langton, G. A. Pearson, A. H. Gregg; honorary registrar, W. R. Gregg.

The proposed system of waterworks and sewage for the town of Gananoque, Ont., as designed by Willis Chipman, C.E., is estimated to cost $120,000, as follows: Intake pipe laid, $5,000; pump house, $4,000; machinery, $5,000; water tower, $7,000; 300 tons of cast-iron pipes and specials with 41 fire hydrants, valves, etc., $13,000; trenching, cartage, pipelaying, lead backfilling, and all other labor exclusive of rock work, $6,000; one third cost of rock in 18,000 feet of trenching, and all the cost in 2,500 feet, $16,000; two sewer outlets, each 400 feet long, $3,000; 24,000 feet of sewer pipes and all other materials, $11,000; 25,000 feet of excavating, pipe laying, jointing, backfilling, and all labor exclusive of rock work, $14,000; two-thirds the cost of rock in 16,500 feet of trenching, and all on 8,500 feet, $36,000.

The following company announcement is among the most important that has been published for some time in the Ontario Gazette: Francis H. Clergue, Bertrand Clergue, Ernest V. Clergue and H. C. Hamilton, of Sault Ste. Marie, and E. S. Douglas, W. P. Douglas and F. S. Lewis, of Philadelphia, U.S., have been incorporated for the following purposes: (a) As a contractor, to construct railway and public and private works of all kinds and to equip the same and operate any of the works constructed by the company except railways; (b) To acquire by legal title mines and mining lands, timber and timber lands, and other lands, and to lease, sell, or otherwise dispose of the same; and (c) To manufacture and sell the products of raw material; the corporate name of the company to be the Algoma Commercial Company, Ltd.; and its share capital to be ten million dollars, divided into 200,000 shares of $50 each; the head office of the company to be at the town of Sault Ste. Marie.

The Elastic Carbon paint which is being put on the market by the Atlantic Refining Co., Toronto, is being warmly recommended for roofing purposes. The company states it to be unexcelled for roofing purposes of every description. It will make a worthless roof practically as good as new and make it serviceable for years at a comparatively small expense when otherwise an entirely new roof would be necessary. It is said to make a roof, be it metal, canvas, wood, felt or shingle, impervious to water; also makes a splendid appearance on metal roofs, it filling the seams and small holes, making them perfectly waterproof, preventing formation of rust. In covering capacity it far exceeds ordinary paint it is said. On felt, paper, canvas and shingle roofs, one gallon covers 100 square feet, while on metal and other smooth surfaces one gallon covers 250 to 300 square feet. It is used for painting bridges, steel plates, vessel bottoms, piers, etc. Gives a lustre similar to enamels and possesses all desirable features of a metal paint. It can be used for agricultural implements, painting fences, pumps, and iron work of any description.

As a result of a meeting of the Canadian Furniture Manufacturers' Association held in Stratford, Ont., on December 27th, 28th and 29th, the British American Furniture Co., Ltd., has been incorporated with a capital stock of $3,000,000 divided into 30,000 shares, of which 20,000 shall be preferred. J. R. Shaw, J. L. Tangher, Toronto; W. H. Hobbs, T. S. Hobbs, London, and Wm. McN. Shaw, Walkerton, Ont., are the provisional directors of the company, which will have its head office in Toronto. So far as at present known twenty-four firms will come under the syndicate. They are: W. R. Hobbs, London; Snyder, Roos & Co., and Schaefer, Keeler & Co., Waterloo; J. S. Anthes Manufactory Co., The Simpson Co., and H. Krug, Berlin; Burr Bros., Guelph; Knechtel Furniture Co., Hanover; Krug Bros. & Co., Chesley; Siemon Bros. Manufacturing Co., Hill Chair Co., and Jas. Young, Wiarton; Watson Malcolm, Kincardine; Broadfoot & Box, Furniture Co., Seaforth; Thos. Bell & Son Manufacturing Co., and Button & Fessant, Wingham; E. F. R. Zoellner, Mount Forest; The Furniture Manufacturing Export Co., Berlin; L. Hahn, New Hamburg; American Rattan Co., Walkerton; Jos. Orr & Sons and George McLagan, Stratford; Union Furniture Co., Wingham.

—The fifteenth annual meeting of the Illinois Society of Engineers and Surveyors was held in Moline, Ill., 24th, 25th and 26th ult. A number of valuable papers were read. Almon D Thompson, president, presided.

Personal.

The employees of the L.E. & D.R.R. presented mechanical superintendent Austin with a Morris chair and an address a short time ago.

Jas. McGregor, British Columbia inspector of metalliferous mines, was reported to be in the Greenwood, B.C., hospital seriously ill with pneumonia recently.

Robert Surtees, C.E., late city engineer, Ottawa, Ont., has been appointed consulting engineer of the Government Commission appointed to expend $60,000 annually in beautifying the city.

T. B. Hart, one of the best known contractors in Ontario, died at his home in Toronto recently, aged 71 years. Mr. Hart was the contractor for the crib-work at the Eastern Gap, Toronto harbour.

J. R. Adamson, manager of a department in the Vancouver, B.C., Hardware Co.'s store, who was formerly in the employ of the Rice Lewis & Son, Ltd., Toronto, was fatally shot while out hunting, January 13th.

The Grand Trunk Literary and Scientific Institute has been made the recipient of a handsome large portrait of Frank W. Morse, the superintendent of motive power, which will adorn the walls of the institute alongside those of other officials of the company.

H. J. Somerset, operating manager of the Winnipeg Electric Street Railway, has received and accepted a position as general manager of the tramways, Perth, West Australia. He is a son of W. B. Somerset, business manager of the Winnipeg Free Press.

Alfred Rubbra, who has been for many years manager for H. W. Petrie, Toronto, has removed to Montreal to take charge of the sales department of the Laurie Engine Co., succeeding Charles Bethell, who has been appointed manager of the Northrop Loom Company's works at Valleyfield, Que.

Samuel Walker, who for seventeen years has been foreman and general foreman at the shops of the Grand Trunk system, at Point St. Charles, having been selected general foreman of the Dominion Bridge Company's works at Lachine, has received a handsome parting presentation from his late fellow employees.

The Cataract Power Company has appointed H. R. Leyden, manager of the Hamilton Electric Light Company, in place of Gordon Henderson. Mr. Henderson and Mark Thomas, late manager of the Hamilton and Dundas railway, have been offered other positions by the company. C. K. Green is manager of the consolidated lines.

The following changes in the staff of the Grand Trunk Railway shops consequent upon the resignation of Samuel Walker are announced: Foreman of erecting shop, J. Farrar; assistant pro tem. to Mr. Farrar, R. Cowan; foreman of machine shop, J. Millington; assistant to Mr. Millington, F. Dalrymple; foreman of wheel shop, A. W. Dutton.

Napoleon Savard, 23 years of age, a telegraph lineman, died from an electric shock which he received while at work in Montreal, January 2nd. He and his brother were replacing and coupling wires at the top of a pole. Napoleon Savard was in the act of splicing two ends of wires. He had no rubber gloves on, and received a strong shock. He grasped the wires convulsively with both hands, and was badly burned, the shock proving fatal.

A. D Benjamin died in Toronto of heart failure last month. Until about a year ago he was senior partner in the well known firm of M. & L. Samuel, Benjamin & Co. Mr Benjamin was born in Melbourne, Australia, 1848, and in 1854 removed to England with his father. He graduated from the University of London in 1865, receiving the degree of B. A. with honors. He first located in Montreal, then returned to England, but finally settled in Toronto about the year 1878, and became a partner in the business already mentioned.

W. A. Carlyle late Government mineralogist of British Columbia, and a most distinguished graduate of McGill University, Montreal, left London, Eng., for Spain about the 1st of Jan., to assume a position which is the best obtainable in the mining profession, namely, the managership of the Rio Tinto mines, Spain, where his salary will be $25,000 a year. In an interview before leaving London he denied the report that his resignation of the managership of Le Roi mine in British Columbia was due in any way to a disbelief in its future. It was simply a question of accepting an infinitely better position. The mining future of British Columbia, he said, was very bright. He spoke of the incalculable harm which he said had been done by the eight-hour law, which checked mining work at a very important time in its history.

J. R. Roy, son of Rouer Roy, Q.C., Montreal, whose appointment as secretary to the Public Works Department was announced a short time ago from Ottawa, received very pleasing testimony to the esteem in which he is held in British Columbia before he gave up his position as Dominion resident engineer there. The New Westminster city council unanimously passed the following resolution: "That this council desires to place on record its appreciation of the services rendered this corporation, from time to time, by J. R. Roy, Esq., C.E., during the four years he has been at the head of the Public Works Department in British Columbia, and, while gratified to learn that his removal to headquarters at Ottawa is in the line of promotion, it cannot but express regret at the departure of an official so painstaking and courteous, and with whom the council's relations have been invariably pleasant and satisfactory." Mr. Roy was also tendered a dinner, which was attended by a large number of well known people.

Electric Flashes.

The Niagara, St. Catharines & Toronto Railway Company will build an electric railway to Hamilton.

The Belleville, Ont., city council has refused an unlimited franchise to the Trenton Electric and Water Company.

The Woodstock, Ont., council, has refused a 50-year franchise to an electric railway between that town and Ingersoll.

An electric line is spoken of to connect the graphite mines near Calabogie, Ont., with the Kingston and Pembroke Railway.

We have received a handsome steel letter opener with bone handle from the well-known electrical firm of Ahearn & Soper, Ottawa.

The right of way granted the Preston and Berlin Railway expired on 15th ult., but it was extended for six months by the Berlin, Ont., council.

Jos. Hughes, formerly employed by the Montreal Street Railway Co., is now superintending the construction of San Paulo Railway, Brazil.

The Electrical Construction Co., of London, Ltd., has recently installed a 500-light dynamo for the North America Bent Chair Co., of Owen Sound.

The London Printing and Lithographing Co., has recently installed a 150-light dynamo, the Electrical Construction Co., of London, Ltd., having the contract.

Alfred Fairbairn, who for a number of years has been paymaster of the Montreal Street Railway, is now comptroller of the West India tramway, Kingston, Jamaica.

Young Bros., iron founders and machine builders, Almonte, Ont., have installed a plant to light their works. They built most of it themselves, and it is most successful.

The Ottawa and Dundas Electric Railway is applying for a charter to build a line from Ottawa, Ont., to the St. Lawrence River in Dundas county, and to build branches.

The Renfrew Electric Light Company has been incorporated and is getting their plant ready. The authorized capital is $75,000. A. A. Wright is president and manager.

The returns at the Interior Department at Ottawa show that the receipts for the first two months that the Yukon telegraph line was in operation amounted to over $13,000.

The Fire and Light Committee of Woodstock, Ont., has been authorized to obtain figures for the purchase of the electric lighting plant and the introduction of an all night lighting service.

The Electrical Construction Co., of London, Ltd., has received an order from John Starr, Son & Co., of Halifax, for an 8-h.p. motor.

The Fraser Cap and Fur Co., of London, has recently placed an order with the Electrical Construction Co., of London, Ltd., for a new increased size of motor for its factory.

The villages surrounding Lake St. John are being gradually lighted by electricity. Roberval has been so lighted for some time, and now Jonquieres is to be similarly illuminated.

The Beattie Mnfg. Co., Toronto, has placed an order for a larger motor with the Electrical Construction Co., of London, Limited.

The dates decided upon for the twenty-third convention of the National Electric Light Association are the 22nd, 23rd and 24th of May, 1900. The meeting will be held in Chicago, Ill.

Achille Gagnon proposes to connect Victoriaville and Arthabaskaville, Que., with an electric railway, providing the ratepayers of Arthabaskaville vote the bonus offered by the council.

The Hamilton-Galt-Berlin Electric Railway Company will apply to the Legislature at its next sitting for an Act extending the time for the building and completion of the company's lines of railway.

The Stratford Clothing Co. has recently placed an order with the Electrical Construction Co., of London, Ltd., for an 8 h.p. motor.

Three motors for operating from 110 volt private isolated plants have been shipped to Winnipeg by the Electrical Construction Co., of London, Ltd., of 12, 4 and 3 h.p. capacity respectively.

The Sydenham Glass Co., of Wallaceburg, Ont., is still adding to its fine equipment of machinery, having recently placed an order with the Electrical Construction Co., of London, Ltd., for a 60-light dynamo.

The Toronto and Hamilton Electric Co., manufacturer of dynamos, motors and all electrical apparatus, has moved into the new premises, which is a ten-story building, 60 x 100 feet, Nos. 99, 101 and 103 McNab street, Hamilton, Ont.

A number of Ingersoll, Ont., business men are taking steps to secure a charter for an electric railway. The charter aims at the same running powers between the towns as the Woodstock, Ingersoll and Thames Valley Railroad Company are seeking.

The Electrical Construction Co., of London, Ltd., has already placed several of the eighty second-hand machines recently returned from Winnipeg. Those who have inspected these machines say there are many good bargains among them.

The city engineer of Hull, Que., is at present engaged in preparing plans for the new dynamo house to be erected, to be in operation by August next. The plans call for 75 arc lights. About six miles of streets will be lighted. Power will be secured from two 50-light dynamos.

The Woodstock Sentinel Review has been considered lately as a model printing house. It has recently added to its already extensive plant an 80-light dynamo and wiring; the contract for which was given and has been completed by the Electrical Construction Co., of London, Ltd., for the multipolar type apparatus

Hon. P. Garneau, V. Chateauvert, J. T. Ross,, Hon. J. Tessier and the Hon. J. Sharples, Quebec; J. McNaught, New York and H. H. Melville, Boston, are being incorporated as the Labrador Electric Light and Power Company, to develop water powers on the Murray Bay River, Quebec, and to build electric lines and paper mills.

The James Cooper Co., Montreal, are suing the War Eagle Gold Mining and Development Co., Ltd., for $150,000, for alleged libel and slander, in connection with the installation of the electric hoist and compressor plant in the War Eagle mine. It is claimed an untrue statement was made, damaging to the Cooper Co., as a business concern.

The inventive talent of the best engineers has been taxed ever since alternating current became popular, to devise a voltage regulator which would be simple in construction and yet be satisfactory in operation; few are said to have attained this. The Chapman Voltage Regulator seems to be meeting with unqualified success. The regulators are manufactured by the Belknap Motor Co., of Portland, Maine, whose Canadian business has been placed in the hands of Munderloh & Co., the well-known electrical firm of Montreal.

Jack & Robertson, Canadian sales agents for Sprague Electric Co., New York, specially call attention to the Flexible Metallic Conduit (pages 103-112, of their new catalogue No. 75), which, owing to its low price, and saving of labor in installing, is said to have considerably reduced the cost of modern conduit work; even more so than did the introduction of uninsulated plain iron pipe.

The Divisional Court at Toronto held recently that the Lord's Day Act does not restrict electricians from working on the Sabbath, as they are not expressly mentioned. Electrician Mashinter, of Huntsville, Ont., was convicted lately for violating the provisions of the Act while at work in Shaw, Cassels & Co.'s tannery, but on the application of solicitors the court quashed the conviction.

The Bell Telephone Company has just completed and opened a heavy long distance copper metallic circuit line between Ottawa, Carleton Place, Smith's Falls and Brockville, Ont. It required upward of 3,500 poles, 4,000 cross-arms and 75,000 lbs. of copper wire. This line gives Ottawa a direct long distance service with Buffalo, N.Y., and other western points, and a material reduction has been made in the rates.

The Niagara and Southwestern Electric Railway Company, Ltd., is applying for incorporation to build an electric railway from Niagara-on-the-Lake through St. Catharines and Smithville to Hagersville, Ont., with branches from Decew Falls to Hagersville via Dunnville and Cayuga, and from Niagara-on-the-Lake to Queenston, passing where necessary through the counties of Lincoln, Welland, Haldimand and Wentworth.

The Electrical Review, New York city, begins the new year with a special double number which is remarkable for its valuable contributions, handsome illustrations and typography. A new dress of type, a change in the color of the cover and a more up-to-date arrangement of reading pages are some of the improvements made. The contents include a review of electrical progress during 1899 in the United States, Great Britain and the continental countries of Europe.

A plan is proposed by Messrs. Denniston and Payne for the development of power at two points at Niagara Falls. The first would be where the Chippewa flows over the bluff in the park. Here it is thought 30,000 h.p. could be developed. Then by conducting the water in a canal through the park to a point below the Falls, and utilizing the fall into the River Niagara, the power could be increased to 100,000 h.p. For this scheme, it is stated that English capital is forthcoming.

That the Canadian Niagara Power Co. will develop power in the Victoria Park is now stated on the authority of W. B. Rankine, vice-president of the company. The actual work will commence next fall, although some preliminary steps will be taken before then. The Canadian plant will be completed within two years, as this was the period required to sink the wheel-pits and construct the tail race on the American side. The first development will consist of from 15,000 to 25,000 h.p.

The Shawenegan Water and Power Co., at the falls of that name, is spending $300,000 this winter, over 1,000 men being engaged. The Shawenegan Carbide Co., of which William Mackenzie, Toronto, is said to be a leading shareholder, has agreed to take 10,000 h.p., while the Pittsburg Reduction Co., whose works are also to be established on the St. Maurice, will also take a great deal of power. Thirty houses a month are being built, and it is expected that the St. Maurice will be dotted all the way from Three Rivers up to the Great Northern Railway by a flourishing manufacturing community.

W. H. Browne, general manager of the Royal Electric Company, Montreal, stated a short time ago that the company had despatched to the Nova Scotia Steel & Iron Company a complete electric lighting plant, consisting of a two phase generator and complete equipment of sixty alternating current enclosed arc lamps. This is said to be the first installation in Canada where an alternating current generator has had its entire capacity taken up with arc lamps alone. He stated further that the company, in conjunction with the Waterous Engine Works, had secured the contracts for the new electric light service to be installed at Greenwood, B.C.

The Court of Appeal has reversed the judgment of the Court of Review and confirmed the judgment of the Superior Court in the case of the Ottawa Electric Company and the Hull Electric Company. By the present judgment the Ottawa Electric Company is declared to have the right to compete with the Hull Electric Company; the bylaw of the city of Hull, Que., giving exclusive rights to the Hull Electric Company, is declared to create a monopoly, and the act of the legislature confirming said bylaw is declared to be unconstitutional.

The establishment of the Marconi system of wireless telegraphy in the northern part of Newfoundland, and along the Labrador coast, seems to be contemplated by the Newfoundland Government, whose Minister of Marine and Fisheries, in a recent interview, stated that the plan at present thought of, if arrangements can be made with Marconi for instruments, fitting up, etc., is to connect the Labrador coast with the nearest telegraph station on the island, probably Tilt Cove. The distance between Tilt Cove and Rameo, Northern Labrador, in a line along the coast, is something over 850 miles. This means that 18 stations at a distance of about 50 miles apart would be placed.

The Metropolitan Electrical Co., Ottawa, is employing 300 men and 50 teams of horses on its power works at Britannia, Ont. There are in operation five steam drills, three steam derricks, a steam dredge, two locomotives and fifty flat cars, comprising part of the plant. The total length of the canal is about 3,000 feet, about 1,200 feet of this is solid rock, through which there is a cutting of about 150 feet wide and varying in depth from eight to fourteen feet. In the blasting of this rock about one ton of dynamite is used a day, and about two car-loads of coal are consumed every day, in operating the plant. The company expects to be in a position to deliver power May 1st. J. Aylen, C.E., is in charge of the works. Thos. Lyndsay, Ottawa, is president of the company.

The Niagara Falls Park Commissioners have reached an agreement with the Fort Erie Electric Ry. Co., under which the latter will be allowed to extend its line for a distance of thirteen miles along the bank of the Niagara River to Slater's Point. This brings the line within two miles of Chippewa, but the ground between the two points is already occupied by the Niagara Falls Park and River Ry., which did not run cars between Slater's Point and Chippewa last season, and the Park Commissioners may cancel the existing agreement and transfer running rights to the Fort Erie Company. In return for the franchise from Fort Erie to Slater's Point the Fort Erie Co. has agreed to buy a right of way, giving a width of 66 feet over the land to be traversed, and to pay a yearly rental.

A recent report respecting the good understanding which is known to exist between the Royal Electric, the Chambly Water and Power Company, and the Montreal Street Railway, is that the latter corporation will buy large blocks of the Water and Power Company's stock. It is also said that the Royal Electric will buy a large interest in the same corporation. It is a well-known fact that the Montreal Street Railway will take a good share—if not all—its power from the works at Chambly, and it is generally believed that between the Street Railway and the Royal Electric, the two consumers of electricity will be able to use up about all the power that the Chambly Company can furnish. The officials of the different companies, while not denying that there are plans on foot, refuse to say anything at the present.

Marine News.

A marine railway is building at Parrsboro, N.S., this winter; local capital having been subscribed.

Innes, Hemeon & Co., general merchants, shipbuilders, etc., Liverpool, N.S., are applying for incorporation as Innes, Hemeon & Co., Ltd.

The Montreal Harbor Commissioners have empowered the chief harbor engineer, John Kennedy, C.E., to prepare estimates and specifications of a powerful dredge, a derrick and four scows, for use in the harbor improvement works next summer. It is estimated that this additional plant will cost about $100,000.

There is a considerable revival of wooden shipbuilding in Nova Scotia, notably at Parrsboro' and Port Greville, where a number of four-masted schooners are being built.

Adam Mackay, Hamilton, Ont., who has returned from England, says the two new boats being built for the Hamilton and Fort William Navigation Company will be ready by June 1.

The Davies Dry Dock Co., shipbuilders, Kingston, Ont., have the contract to build a steamboat, 70 feet long, for a Rat Portage firm. It will be completed in time for the opening of navigation.

The new wharf to be built by the Richelieu & Ontario Navigation Company at the foot of Scott street, Toronto, will be completed by the 1st of April, and will cost $23,000. The wharf will be 357 feet long and 54 feet wide. On it will be erected freight sheds, waiting rooms and ticket offices for both the Hamilton Steamboat Line and R. & O. Company.

R. J. Leslie, Halifax, N.S.; J. McLean, Souris, P.E.I.; William McKenzie, Pictou, N.S.; E. G. Kenny, Halifax, N.S.; J. G. Binet, Magdalen Islands, Que.; G. C. Hart, Halifax, N.S., and W. G. Leslie, Magdalen Islands, are applying for incorporation as the Magdalen Islands Steamship Company, Ltd., with a total capital stock of $100,000, headquarters at Halifax, N.S.

Railway Matters.

The pension system recently introduced by the Pennsylvania railways is taking root on the other lines.

The Quebec Central Railway Co. gave its office employees a raise of ten per cent. on their salary as a Christmas present.

The Mineral Ry. Co. asks a charter to build a railway from Gros Cap Harbor on the north shore of Lake Superior to the Canadian Pacific Railway.

It is said that the Canso and Louisburg Railway Co. is contemplating the construction of a bridge across the Strait, which, it is estimated, will cost $3,000,000.

The Montreal and Ottawa Railway Co. is applying for an Act extending the time within which it may complete its railway and connect it with the railway of the C.P.R. in Ottawa.

The Canada Atlantic Railway Co. intends building a second elevator at Depot Harbor, Ont., with a capacity of 1,500,000 bushels, this season. It will also add three new steamers to its grain fleet on the upper lakes.

Incorporation is asked for the Crow Lake Railway and Development Co., to construct a railway from White Fish Bay, Lake of the Woods, easterly to a point in Crow Lake, and to operate same by steam or electricity.

Application will be made for incorporation of a company to construct a railway from near Cascade, B.C., in a westerly direction to Carson, with a branch from Grand Forks fifty miles up the North Fork of the Kettle River, following the valley of the same river, also with a branch from a point at or near Grand Forks in a southwesterly direction by way of Greenwood, to Midway.

The Manitoulin and North Shore Railway Co. will apply to the Ontario Legislature at its next session to empower it to build from Little Current to James Bay, and from the township of Drury to Sudbury, and also from Little Current to the south shore of Manitoulin Island, and from Tobermoray in the county of Bruce to Meaford, passing through Wiarton and Owen Sound, Ont.

The Athabasca Central Railway will apply for a charter at next session of the Dominion Parliament to build a railway from Edmonton to Victoria Settlement and the Athabasca River, and on to Vermillion Falls on the Peace River. The company will also ask power to mine, smelt and manufacture iron, etc., and develop asphalt, gas, tar, and petroleum deposits, and do a general trading business in lumber, etc.

Application will be made to the Ontario Legislature for incorporation for the Wabigoon, Manitou and Rainy Lake Railway Co. to build a steam or electric railway from the south-eastern end of Minnetakie Lake or Mine Centre, and from a point on the Canadian Pacific Ry. between Dryden and Tache

Station, southerly (east of Manitou Lake), to a point on the Ontario and Rainy River Railway between Fort Francis and Sturgeon Falls.

Application will be made at the next session of the Dominion Government for a charter for a company to construct a line of railway from Collingwood to Toronto, Ont., and also to maintain a fleet of vessels to run between Toronto and the River St. Lawrence. W. Mortimer Clark, Q.C., is the solicitor for the applicants, the names of whom have not as yet been made known. Mr. Mortimer Clark says there is plenty of money in the company, which is composed of financial men The new railway will do a grain-carrying business principally.

Application will be made to the Ontario Government for the incorporation of the Crow Lake Railway and Development Company, with power to construct a railway from a point on White Fish Bay, Lake of the Woods, to a point on Crow Lake, and to operate same by steam, electricity or other motive power, also with power to build and operate steamboats, saw mills, electric power plants, hotels, stores, wharves, milling plants, and to operate and develop mines, and to obtain the exclusive privilege of carrying on the business of fishing in Crow Lake.

The Dominion Iron and Steel Co. propose to construct a line of railway from its quarries at George's River, to connect with the I. C. R. about midway between the George's River station and the North Sydney junction. Grading has already commenced, and it is anticipated that early this month, when the stone crusher and compressor are expected to arrive, the company will be in a position to ship material over the new line to the works here. A bridge will span the river opposite the quarries. Martin Stephens, of Belle Isle, Nfld., has been appointed manager of the quarries.

Mining Matters.

T. B. Caldwell is developing extensive water powers at his iron mines at Calabogie, Renfrew county, Ont.

It has been announced that the Slocan, B.C., miners have accepted the Payne's offer of $3.75 per day of eight hours.

The expenditure of the Dominion Coal Company in Nova Scotia exclusive of royalty and wages is about $600,000 annually.

The big shafts being sunk by the Dominion Coal Company, near Glace Bay, C.B., are down, air shaft 100 feet and main shaft 130 feet.

A great boom in copper development is predicted by M. H. Fitzpatrick, Pictou, N.S. The Crown Copper Co. is making great progress.

Very extensive discoveries of hematite are reported from Visso's Ridge, near Portugal Cove, Nfld. The ore is similar to that at Belle Isle.

There have been fresh discoveries of petroleum in Cape Breton at Lake Ainslie. A flowing well was recently struck at 565 feet, the Sydney Record says.

The Lake Superior Mining Institute will hold its next meeting at Iron Mountain, commencing 6th February next. The secretary is F. W. Sperr, Houghton, Mich.

The prospectus of the Sultana Mine of Canada, Ltd., states that the mine was bought from J. F. Caldwell, Winnipeg, for £225,000, all of which Mr. Caldwell took in stock.

Natural gas was struck in the Queen Victoria Park at Niagara Falls, Ont., where test borings were being made preparatory to calling for tenders for the power tunnels.

A. E. Martin has discovered extensive veins of graphite running from 35 to 50 per cent flake graphite on the farm of O. McCoy, on the River Blanch, St. Malachy, Que. There is said to be a fine water power in the neighborhood.

Great activity is noticeable in mica mining in the Gatineau River district, particularly in Hull, Wakefield and Templeton townships. The Blackburn Bros., Wallingfords, Sills Mica Co., A. H. Murphy, and a great many smaller operators are producing large quantities.

The prosperity in the iron industry has directed renewed attention to the iron resources of Quebec, and it is likely that the Bristol, Old Ironsides and Haycock mines in Ottawa county, which have been shut down for a number of years, will be reopened shortly.

The Crown Copper Company expect to have their furnaces in operation in about four weeks or sooner. The engine is up and has been tested. A powerful dynamo has been set up, and the wiring of the large buildings is going forward.—Mining Record, January.

C. E. Mitchener, M.E., New Philadelphia, U.S.; C. H. Howland, Cuyahoga Falls, O.; H. Totten and N. F. Davidson, Toronto, Ont.; and W. McVittie, Sudbury, Ont., are applying for incorporation as the Canadian Nickel Co., Ltd.; capital to be $900,000; head office, Worthington, Ont.

It is understood that by the opening of spring arrangements will have been completed for the construction of a silver-lead smelter at Moyie Lake, B.C. Both furnaces at the Hall Mines smelter at Nelson are in blast. The one hundred ton furnace is running on lead ore, and the big one on Silver King ore.

At Thetford, Que., the Bells Asbestos Co., King Bros. and Johnsons are the principal operators in asbestos. At Black Lake mining has been resumed by the Glasgow and Montreal Asbestos Co. The property formerly worked by the American Asbestos Co. is now known as the Union Mine and is being worked by a German company.

The Mikado Mining Co., of which T. R. Deacon, C.E., of Rat Portage, is the Canadian director, has just installed a sorting plant in their 20 stamp mill at the Mikado mine near Rat Portage, in order to increase the efficiency of their present batteries. By this means it is expected that the output of bullion which has been running about $12,000 per month, will be increased, as there is plenty of good ore in sight.

J. Patterson, J. Moodie, W. Southam, C. W. Moodie, J. R. Moodie, J. M. Harris, S. Barker, W. W. Osborne, J. J. Scott, J. Dixon, A. T. Wood, T. H. Macpherson, J. T. Glassco, J. Knox, J. H. Tilden, J. Milne, G. E. Tuckett, H. B. Witton and J. W. Sutherland, Hamilton, Ont., and J. A. Kammerer, Toronto, have been incorporated as the Nickel Copper Co., of Ontario, Ltd.; capital, $10,000,000; head office, Hamilton. The company proposes to carry on in all its branches, mining, milling and reducing.

Mining industries are still attracting attention in the vicinity of St. Stephen. The English syndicate is working on its shaft on the Hall farm. The ore is looking well. Another company is now at work near Moore's Mills getting ready to sink a shaft. They claim to be on the same nickel ore that crops out on the Hall farm. Still another company, a Boston syndicate, will soon operate on the Magguerrock Mountain claim, on the American side of the river, above Milltown. It looks as if there would be quite a mining boom on the St. Croix in the near future.—St. John, N.B., Telegraph.

News was brought by the steamer "Danube," from Skaguay to Vancouver, December 19th, of the reported discovery of a vast body of free milling ore, within ten miles of Dawson. The Yukon Sun says it is one thousand feet in depth, one mile wide, of unknown though great length, assaying as high as $860 to the ton. Over twenty claims were recorded in that locality up to November 7th. The exact location of this ore body is given as the left bank of the Yukon, seven miles above Dawson. It is neither a deposit of gravel nor a quartz ledge. As defined by a Dawson metallurgist, it is an oxidized mass of quartzoric porphyrite rock, containing more or less gold throughout the porous oxidized material, as well as in hard quartzite.

S. J. Ritchie, Akron, O., has begun a suit for $1,200,000 damages in the Common Pleas Court against Stevenson Burke, N. P. McIntosh, C. W. Bingham and the other directors of the Anglo-American Iron Company. Mr. Ritchie, who originally discovered valuable deposits of mineral in the Sudbury district of Ontario, has been in constant litigation for years with the Cleveland capitalists who were interested with him in developing the field. The suit filed January 13th, alleges that the defendants are in the control of the Anglo American Iron Company, who also control the Canada Copper Company, which has properties in the same neighborhood; they have neglected and refused to

operate the mines and mills of the former company, while pushing the property of the latter. The Anglo-American Iron Company, he says, could earn $300,000 a year, and he asks the judgment in behalf of all the shareholders, except the defendant directors.

MEASURES AND RULES.*

BY P. TROWERN.

Before I enter on fractions or decimals I would like to tell you how the mechanics' rule was brought into use (our foot rule I mean). A long time ago measurements of land were made by a person stepping it, one foot before the other in a straight line, which were called so many steps by the land surveyor, and the small pieces were measured by their feet, the heel of one foot touching the toes of the other, which made it so many steps, and feet disputes soon arose between the people and the surveyors so that the Government had to make laws for the people, and in 1760 a number of men's feet were measured, and they came to the decision that a step should agree with 3 feet, called a yard, and that a foot should be divided into 12 equal parts, called inches, so you see the yard became a unit, and a foot was 1-3 of a yard, a fraction or piece, and the inch, 1-12 of a foot, became a fraction, or a small part of the 36 inch yard; a gold rod was made and marked off in feet and inches as a standard belonging to the Government in England. All countries do not agree with regard to the length of the foot; 46 French feet is equal to 49 English, 35 German feet are equal to 57 French; the Russian foot is equal to the English foot, the old Turin foot was equal to 20 inches, and the inch was divided into 12 parts; in all the Prussian States the length of the foot differed; the inch in England and Canada is divided into 8 parts to commemorate or keep before our eyes or knowledge the very useful and mechanical members of our bodies; our two hands and arms, our two legs and feet, equal 4 or ½ inch, and our two eyes and our two ears make the 8 parts, or the vulgar fractions; this word was not then used as it is now, but to show the parts of the whole unit, the yard. The French said that we have as great a national right to show our love and respect to our five fingers and toes as to any other part of our body, which induced them to divide their foot into 10 parts, and their inches into 10 parts; by so doing they brought into general use among themselves the decimals, 5 on one hand and 5 on the other, equal 10, and 10 toes equal 20, and this $20 \times 5 = 100$, which they called a unit; this unit x by $10 = 1{,}000$, and so on. I will now draw your attention to the fractions of our 12 inch rule; we say so many feet, inches and eighths; what I conceive it to be our duty in this society is to keep before our mind the use of our rule and calculations of our foot rule; if you wish to practise fractions make your calculations with the different fractional parts of it, keeping before you our mechanic's rule as a unit; ½ of 12 inches equals 6, ¼ equals 3, 1-12 equals 1; the division of the 1 inch are vulgar fractions, ½ of an inch equals 4-3, ¼ equals 2-3 and ½ equal to 1 of the 8 parts the inch is divided into, or if you wish to divide it more, 1-16, 1-32 and so on, and to have mixed fractions you may say 1 foot 3 inches and ⅞ and a 1-32; and if you wish to add a number of them together it is easily done.

In 1788 the French people asked their Government to have a standard by which all their weights and measures might be made and compared. A number of scientific men were called together to devise a standard, which they did by taking a fourth part of a meridian of circumference of the earth. This fourth part of the line was divided into 10,000,000 equal parts, and each part was called a metre, which is equal to about 39 English inches; this metre is divided by 10, and called a decimetre, and by 100 and called a centimetre, by 1,000 and called a millimetre. To obtain the other measures a cubical box was made, exactly on each of its sides 1 100 part of a metre, or one centimetre; this was filled with water at its greatest density, and the weight of this water was called a gramme; a gramme was divided by 100, and it was called a centigramme.

*From a paper read before No. 1 C. A. S. E.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports from Great Britain of interest to the metal trades for the month of December and the twelve months ending December, 1898-99.

	Month of Dec.		The year to December.	
	1898.	1899.	1898.	1899.
Hardware	£1,278	£2,299	£21,578	£21,69
Cutlery	2,831	4,102	51,374	53,795
Pig iron	42	2,043	11,043	38,366
Bar, etc.	1,429	1,133	10,478	34,061
Railroad	12	100	9,195	152,981
Hoops, sheets, etc.	1,627	1,282	63,605	111,653
Galvanized sheets	623	322	65,176	69,515
Tin plates	13,090	14,043	168,627	249,513
Cast, wrought, etc., iron	2,182	5,892	26,820	67,783
Old (for re-manufacture)	—	683	4,324	8,408
Steel	2,282	17,149	48,844	157,504
Lead	1,041	1,277	36,092	44,855
Tin, unwrought	759	1,979	16,601	25,922
Alkali	1,705	2,332	50,028	44,656
Cement	487	449	25,595	38,749

ONE FIRST-CLASS MARINE BOILER

Eight feet long, 4 feet 8 inches wide, 86-2½ tubes, 6 feet long. Allowed 115 lbs. steam. Been in use 4 years. DAVIS DRY DOCK CO., Kingston. 2-1

FOR SALE

Canadian Patent Rights in **Meter for Recording the Volume of Water and Power** used by hydraulic power plants. Correspondence solicited.

C. P. RUTTY, 742 Prudential Bldg., Buffalo, N.Y. 2-1

FOR SALE

A good Water Power, 500 horse, situated one-half mile from railway, every facility for making siding to power. Address

J. D. THEUNISSON, Cookshire, Que.

Bridge Tenders Wanted.

Sealed Tenders (marked tenders for bridge) for the superstructure of a steel bridge over the South Nation River at Lemieux, on the boundary line between Prescott and Russell, Ont., will be received by the undersigned up to the 20th January next, inclusive (1900).

Separate Tenders for the construction of the "abutments" of said bridge will be received by the undersigned up to said 20th day of January next, inclusive.

Plans and specifications of said bridge (iron work and masonry) may be seen and further information obtained, at the office of the undersigned, in the Court House in the Village of L'Orignal.

The lowest or any tender not necessarily accepted.

E. ABBOT JOHNSON,
Clerk United Counties of Prescott and Russell.

L'Orignal, December 12th, 1899.

ST. LAWRENCE CANALS

NOTICE TO ENGINE AND BOILER MAKERS.

Sealed Tenders addressed to the undersigned and endorsed "Tender for Engines and Boiler," will be received at this office until sixteen o'clock on Monday, 5th February, 1900, for the construction, &c., of two non-condensing marine engines and a Clyde boiler.

Specification of the work can be seen at the office of the Chief Engineer of the Department of Railways and Canals at Ottawa, and at the Superintending Engineer's Office, Corn vall, where forms of tenders can be obtained on and after Saturday, 20th January, 1900.

In the case of firms there must be attached the actual signatures of the full name, the nature of the occupation and place of residence of each member of the same, and, further, an accepted bank cheque for the sum of $500 must accompany the tender; this accepted cheque must be endorsed over to the Minister of Railways and Canals, and will be forfeited if the party tendering declines entering into contract for work at the rates and terms stated in the offer submitted. The accepted cheque thus sent in will be returned to the respective parties whose tenders are not accepted.

The lowest or any tender not necessarily accepted.

By order,

L. K. JONES
Secretary

Department of Railways and Canals,
Ottawa, 18th January, 1900.

Newspapers inserting this advertisement without authority from the Department will not be paid for it. 2-1

The Canadian Engineer

VOL. VII.—No. 11. TORONTO AND MONTREAL, MARCH, 1900. PRICE 10 CENTS $1.00 PER YEAR.

The Canadian Engineer.

ISSUED MONTHLY IN THE INTERESTS OF THE CIVIL, MECHANICAL, ELECTRICAL, LOCOMOTIVE, STATIONARY MARINE, MINING AND SANITARY ENGINEER, THE SURVEYOR, THE MANUFACTURER, THE CONTRACTOR AND THE MERCHANT IN THE METAL TRADES.

SUBSCRIPTION—Canada and the United States, $1.00 per year; Great Britain and foreign, 6s. Advertising rates on application.

OFFICES—62 Church Street, Toronto; and Fraser Building, Montreal.

BIGGAR, SAMUEL & CO., Publishers,
E. B. BIGGAR, R. R. SAMUEL
Address—Fraser Building, MONTREAL, QUE

Toronto Telephone, 1392. Montreal Telephone, 2589.

THE INTERCEPTION TRAP.

BY W. M. WATSON.

For THE CANADIAN ENGINEER.

About forty years since I began to learn the sanitary trade, many private drains were built with rough stone, bricks, broken pipes and wood; they were totally void of any scientific arrangement or rule; no regard was paid to grading, and often the level turned the wrong way, which of course made the channels useless as carriers of sewage. Such private drains only distributed the poisonous sewage among the subsoil of the premises they were laid under, making the ground a cesspool of impurities that generated foul gases and contaminated the living rooms of the dwellings.

This state of things caused an appalling death rate among young children, who spent most of their time in such polluted atmospheres. To add to the leaky and unsanitary state of such private drains it was only in a few of the best plumbing jobs that either the soil pipe, the waste pipe or the head of the drain pipe line, was continued upward to above the house roof with a view of ventilating the plumbing, the private drain line and the public sewer.

To have cured this defect was simple enough, by having the drains laid with good sound pipes, tightly jointed and scientifically laid by competent workmen, and the terminating head of every drain, soil pipe and drain pipe carried up to above the highest point of the roof of the building, so as to ensure a good circulation of air from the street sewer upward through the line of pipes. However, the usual methods of tackling such difficulties was adopted. Professional engineers and scientists made a big thing out of the sanitary cow, and meetings and lectures were many, to make a remedy for so serious an evil, and the result was that W. P. Buchan, Glasgow, got the pull and inaugurated the system in 1872 of placing an interception trap in all private drains at a point where the private drain entered private property, or buildings. His argument was that no poisonous sewer gas could pass from the public sewers to the private house, if this shut-off valve or interception trap was fixed into the private drain; but he took no note of the fact that the putrid matter that poisoned the dwelling was under the dwelling, and not in the street sewer at that time, and if the street sewers were so badly laid that they generated poisonous microbes, the very best way was to provide plenty of means to draw off the foul gases to a point of the atmosphere above the house tops, where they would at once die, for dangerous microbes can live only where there is no circulation of air, and no better carrier of air or gas can be found than the warm moistened walls of a sewer or soil pipe.

Our Glasgow friend no doubt was a thinking man, but he evidently was not sufficiently well informed to know that when public sewers are scientifically laid, they are self-cleansing and self-aerating. When that is accomplished the sewage is kept moving until it reaches the sewage outfall, on that ground the foul matter entering the sewers cannot breed or incubate microbes, nor generate foul gases of any kind, because such putrefaction can only take place in very sluggish streams and cesspools, two things that are not admissible in a well laid drain. Then with regard to aeration of the sewers, if both the sewers, the private house drain, and the plumbing be scientifically designed, and worked out, every pint of sewage discharged from the house fixtures into the drain will carry with it into the main sewer about one quart of fresh atmospheric air, about sufficient to clean out and purify it. When the time arrives that a reasonable amount of common practical knowledge is used when constructing sewer drains and plumbing, the sewers themselves will do a great deal towards cleaning and purifying, by the help of bacteria, the foul liquid that is put through them. The system of Mr. Buchan prevents all this good work by placing the interception traps on all private drains, because the drains cannot have the proper and natural ventilation, nor can the sewage carry air into the sewers; moreover the sewers cannot be self-cleansing, in fact, it turns the whole system of sewers into a poisonous gas making machine, that has already sent many to a premature grave and will send many more before the fad works itself out.

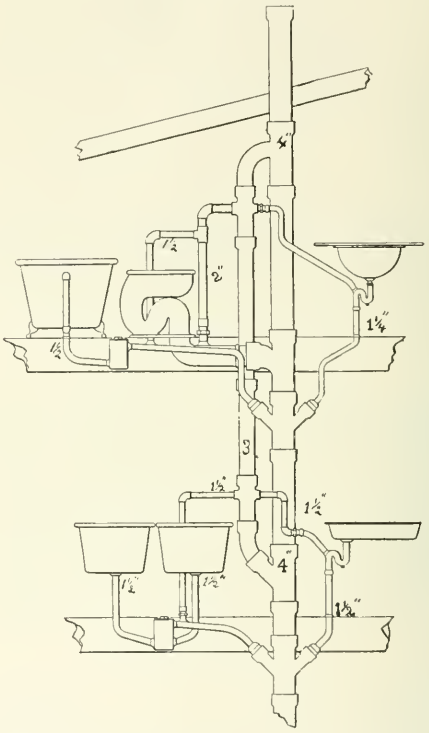
The time is ripe for reliable statistics to be published showing the sickness and death rate of the inhab

itants living in houses having the interception trap on their drains, and similar houses that have not, so that the public would be enabled to judge for themselves whether or not it is a dangerous innovation. Though this would only show a small part of the danger and the injury done, because the whole sewage system of the town is fouled for the want of the ventilation which the interception trap prohibits.

The introduction of the interception trap has given sanitary theorists a large field wherein they have introduced many kinds of machines to try and aerate the drains, and flush the sluggish sewers, and by so doing prevent the generating of foul gases, but at every point they have met with poor success, and many of the public streets are charged with foul odors coming from the sewer manholes, and people living in elevated places where the town sewer gas is driven have often to suffer contagious illnesses, simply because the town sewers are not ventilated by natural principles, or in other words let me say that nature is not allowed to perform her appointed duty; if it was, then the making of obstructions in the flow of sewage and sewage aeration would cease. Sewage ventilation would be fully secured by using the simple and natural means that is at hand when the interception trap is left out. To do this all private drains must be inserted in the crown of the street sewer, and continue on a rising grade free from any obstruction until the line arrives above the roof of the building, and all the waste pipes of all the conveniences on the premises must be connected with the vertical soil pipe separately by a short branch and trap.

There are more injurious excesses and unscientific obstructions placed in the sewage and plumbing appliances at the present period, than I have ever witnessed during my forty years' experience, and these excesses are as expensive as they are useless, and many of them are dangerous to the public health.

Fads being catching it is only the excessive cost that has prevented many councils from destroying their present system of ventilation by compelling their townspeople to adopt the interception trap principle in their house drains. To show the excess that plumbing has arrived at I ask the reader to study a drawing of R. M. Starbuck's, published in The Sanitary Journal of New York, which is a fair drawing, showing how plumbing must be put together in many cities and towns which consider their sanitary business the acme of perfection. The drawing shows at least twice the amount of pipes and joints that are necessary to make safe and first-class sanitary jobs that will work freely. It also shows the waste pipes from the conveniences to be arranged and carried out to the soil pipe connection in a way that cannot meet with approval of an expert experienced plumber. There is too much pipe used, and it is not well arranged. I gave sketches, and the reasons for making this remark in my article on plumbing in February issue of 1869 and September issue, 1868; these two articles give detail reasons for several assertions made in this paper. The 3-inch main line ventilation pipe shown to be joined by a branch to the 4-inch soil pipe near the washtubs, and again at a point just under the roof, cannot have any circulation of air, for no current passing up the soil-pipe can be made to branch off and return into the soil-pipe again without the use of force. It is possible to turn the air round the 3-inch by-pass, by placing a stop valve in the 4-inch soil pipe, somewhere between the two 3-inch branches, but by no other natural way, so we can safely say that the so-called 3-inch ventilation pipe, together with its five branches that lead to the five different conveniences, are no ventilation pipes at all. The only office they can perform is to form a relief, so that when the contents of the pipes contract or expand they will throw out, or take in the small quantity of air needed to balance the space.



But there is another duty that they are credited with performing, viz., they prevent the key of water (that forms the air valve in all traps), from being syphoned out. When plumbers arrange the waste pipes from the bath and sinks in the way they are shown in this sketch, they do their level best to coax the traps that serve the fixtures to be syphoned, but there are reasons why they never do syphon, when used in the usual domestic way, they never did syphon nor they never will, but if the waste pipes were connected to the soil pipe in a proper mechanical way, they could not be syphoned, if every pipe, including the soil pipe, was running full bore at one flush, which is an action that can never happen in the usual way of using them. Experiments have been repeatedly made, and the results have shown that such vent pipes are no use, but on the other hand do much harm, and are responsible for many premature deaths; this, too, has been personally proved.

The oldest plumber never found a trap on a house pipe dried out by evaporation before the fad of venting all traps was introduced, because the drying influence of the atmosphere on the house side of the trap was balanced by the condensing of the sewer air and moisture present on the sewer side of the same trap. When a vent pipe is connected to the sewer side of the trap it

abolishes the moisture feed that the trap formerly had, and applies another drying influence into the traps, so that evaporation is going on both on the house and sewer side of the water seat, that is lodging in the dip of the small trap, therefore, it is only a matter of a few hours for the seal of the bath trap to become broken, and a passage is then open to introduce the gas from the sewers into the sleeping rooms, and it is by this method that some of our best houses have diphtheria and typhoid.

It may be safely said that where one trap can be found with its seal broken, because it has been syphoned, fifty traps can be found that have had the seal broken and dried out by evaporation, caused by the air coming in contact with the water on both sides of the trap, and on account of having a ventilation pipe placed on the sewer side of the trap, as has been shown.

SOUTH AFRICA, ITS PEOPLE AND TRADE.

CAUSES OF THE BOER WAR.

ARTICLE V.

(Continued from last issue).

A word as to the commercial situation. In the year 1884 the revenue of the Transvaal was £161,596, and the expenditure, £184,820. The population at that time was about 45,000, of whom 35,000 to 37,000 were Dutch. That was the year when Kruger went to England to obtain the new convention. The finances of his country were in bad shape, and remembering what England and Englishmen had done to rehabilitate the country financially during the three years of British administration, he had a letter published in the London papers inviting British capitalists, miners and merchants to come and settle in the Transvaal. They accepted the invitation, and in 1885—86 the De Kaap and Witwatersrand fields were discovered, with the result that the revenue for 1898 was £3,329,958, practically all of which is derived from the energies of the Uitlander. In the face of this, Kruger now asks, and the pro-Boer organs throughout the world echo the question: "If the Uitlander does not like the treatment he gets, why does he not stay away?" The Uitlander, upon Kruger's invitation, came to the country, discovered the gold, and built up the industry. Should he be robbed of the business he has created? And if prior occupation is urged by the Boer, how about the Kafirs, whom he has dispossessed of their lands? But while an unnecessary revenue, such as this, is squeezed from one element of the population, the expenditure has gone on to keep pace with it. This year the civil service list amounted to £1,216,294, or enough to give £40 to each male inhabitant of the country. The ordinary expenditure last year was £3,476,844. A large part of this, as stated, goes to build up a military power to overawe and oppress the very people whose exertions provide the money; much of it, according to Cecil Rhodes, has gone as a bribery fund to influence elections in the Cape Colony, and carry on the propaganda for seducing the Cape Dutch from their allegiance to Britain. A huge secret service fund* is used largely for political purposes in Europe to the same end; while a large but unknown sum is given by the President himself, as "doles," to Boers in the back districts, ostensibly to help farmers in distressed circumstances, but in reality to keep burghers loyal to him. The various monopolies also yield large bribery funds. The dynamite monopoly, by which the sole right to make or sell dynamite was given to one man (afterwards a syndicate), who was permitted to charge 200 per cent. over what the article would cost in the open market, filches from the Witwatersrand mines alone £600,000 a year. Space forbids reference here to the other monopolies, but it may be noted that these monopolies are given to Kruger's favorites on articles that are chiefly imported from Great Britain, or are used chiefly by British subjects. This is one of the numerous violations of the conventions, which provided that the taxation should be equal to all classes. It may also be noted that President Kruger has not only defended these monopolists under all circumstances, but in the numerous cases in which boodling schemes have been unearthed, and scandals exposed —sometimes by honest men in his own party—he has invariably shielded the boodlers and not infrequently promoted them or given them fresh opportunities.

A great deal might be said on the external relations of the Transvaal. The convention of 1884 fixed the boundaries of the Transvaal exactly, and the republic undertook solemnly to respect the independence of native chiefs outside its territory. Scarcely a year has passed without the violation of the convention in this respect. One of Kruger's first acts was to invade part of the British Protectorate and proclaim it a portion of the Republic, following up the operations of some of his free booters. And he only withdrew because of Mr. Rhodes' protest and the Warren expedition, which cost the British Government over £1,250,000. Then the Boer Government turned its attention to Zululand, which, after an intrigue with Dinizulu against the other chiefs, it invaded and attempted to upset the settlement made by Lord Wolseley. Next they invaded the country of the Matabele whom they had driven out of the Transvaal originally, and who were now under British protection, and they were only turned back by the tact and firmness of Dr. Jameson. Again they tried to lay hands on Tongaland, but the Queen Regent would have nothing to do with any country but England, whose protection she had sought. The invasion and spoliation of Swaziland was another Boer outrage, which Great Britain, from a mistaken notion of keeping peace with the Boers, condoned.

Such are a few of the features of Krugerism in South Africa, and the reader can judge whether they are such as to justify the interference of Great Britain.

It is a subject of wonder to many that the Boers persist in a course which a large number of them must know to be wrong, and stand out against the whole might of the British Empire in so doing. It must be remembered, however, that the vast majority, who never read a newspaper, or a book, except the Bible, are as ignorant of the outside world as the Hudson Bay Indians. Perhaps not ten of the whole body of burghers ever saw a man-of-war or visited England or Europe. Even Kruger and the other members of the Volksraad, who visited England, saw little of its resources; and it must be admitted of Kruger, who is a man absolutely without fear, that if he had the clearest realization of Britain's power, it would make no difference with his policy, so convinced is he that the Boers are the only favored nation of Heaven. What can be

done with a man who believes (as Kruger argued with Dr. Hertz, and a deputation of Johannesburg Jews, who came last year to plead for educational freedom), that the Boers are the direct descendants of Isaac, and the Jews the descendants of Ishmael, and that, therefore, it would be against the Scriptures for both people to inherit the land together! It must also be understood that, whatever the Boer leaders know, the Boers themselves are convinced that when the Gladstone Government gave back the country in 1881, it was through fear, and that the profession of generosity or justice was merely a cloak for this fear. And they point, in confirmation, to the fact that when Mr. Gladstone, after denouncing the annexation, in his Midlothian speeches in Opposition, came into power, he refused all along to restore the Boer Government until he had the experience of Majuba Hill. The leniency with which the British Government treated the Transvaal in its repeated violations of the two conventions, and the way in which they were allowed to despoil the Swazi tribe, were to the Boer mind only so much accumulating evidence of this fear, apparent to him as the years went on. Perhaps Kruger himself thought the Transvaal was a match for Britain, as J. P. Fitzpatrick relates the following, in his "Transvaal from Within:" "The late W. Y. Campbell, as spokesman of a deputation from Johannesburg, addressing President Kruger, stated in the course of his remarks that the people of Johannesburg 'protested' against a certain measure. The President jumped up in one of his characteristic moods, and said: 'Protest! Protest! What is the good of protesting? You have not got the guns! I have.' And Mr. Campbell, in reporting this in Johannesburg, remarked: 'That man is sensible; he knows the position. I claim to be sensible, also, and I know he is right; you can take my name off any other deputations, for we'll get nothing by asking.'"

We have evidence that several members of the Raad would have given the Uitlanders, not all, but some of the rights they vainly sought, but Kruger had become too powerful an autocrat, and they were no match for him either in diplomacy or determination. But though the Boers were ignorant, they were not so ignorant as to fail to realize that if the franchise was granted to Uitlanders, and a clean, honest administration inaugurated, these "doles" to burghers would cease, and they would no longer be able to live in ease at the expense of the hard-working alien. Hence, their determination to do what would otherwise appear insane—to risk the destruction of the Republic itself rather than to do justice at the cost of giving up control.

(To be continued).

CANADIAN NICKEL-STEEL.

The nickel-steel age, spoken of by Prof. Roberts-Austin before the British Association for the Advancement of Science, as being the next great period in the industrial progress of the world, is now entered upon. The most learned metallurgist in the world, whose opinion we have just quoted, also predicted that Canada would take a leading part in the developments which would characterize that epoch. There is no reason why the nickel-steel supplies of the world should not come from Canada. We can make iron cheaper than anywhere else in the world. We have the greatest and cheapest nickel supplies, because Canadian nickel contains enough copper to pay for getting it out and treating it, therefore the nickel-steel can be produced by us at prices which defy competition.

Hamilton, Ont., is to be the seat of great metallurgical industries. To the iron smelter and rolling mills already there, is now being added the Hoepfner Refining Co.'s works, which will refine zinc, copper and nickel. To operate this plant 3,600 electrical horse-power will be required, which will be furnished by the Cataract Power Co. J. Patterson stated publicly on March 1st, that contracts had been made with the Canadian Nickel Company, the Nickel Copper Company of Ontario, and the Hoepfner Refining Company, for the refining of nickel matte, the contractors to supply sixty tons of matte a day to the Hamilton works. As soon as the Hoepfner Co.'s plant is an accomplished fact, which will likely be in the coming spring, the nickel-steel plant will be started, and the cost of the buildings and machinery will be about $6,000,000.

For THE CANADIAN ENGINEER.

PEAT AS FUEL IN CANADA.

BY A. G. ARDAGH.

Peat or turf is usually associated in our minds with the old home-land, but there are many who do not know that in our country we have peat bogs of similar character. Swamp land, as we know, is widely distributed in the Dominion, but the product is not recognized by old country people as turf, which is generally the product of mosses; of the latter there exists, nevertheless, large deposits in Ontario and other Provinces. Both kinds of peat can be utilized as fuel. These peats are decomposed mosses, sedges, aquatic plants and other vegetable matters. Dana says: "In temperate climates it is due mainly to the growth of mosses of the genus sphagnum. This plant forms a loose turf, and has the peculiar property of dying at the extremity of the roots below while it continuously grows and increases above the surface, and by this process a bed of great thickness is gradually formed." In "older" peat there are a few traces of fibrous matters, but it presents a pitchy, shining hue when cut. It will dry out more or less brown. In "recent peat" the fibrous condition is closely marked and the color brown.

In general the older peat is underneath, but the lower stratum may be immature peat. This is the case in the Ellice marsh, nine miles north of Stratford, Ontario, where there is a bed of several thousand acres of sphagnum peat about six feet deep. The moss has been burnt off the surface long since. On the great bog in the County of Welland a number of acres are still covered with the original sphagnum moss. It is curious that these marshes are usually to be found on the watersheds. Peat contains in undrained marshes about 90% of water. It parts with its water very slowly on exposure to the air when in the shape of bricks and out of contact with the bog. On the peat moors of Ireland, Scotland and Northern Continental Europe, turf has been, since time immemorial, cut out in brick form and marketed locally in its crude state, although previous to this many fruitless efforts have been made to compress it economically and on a commercial scale. In this way the

efficiency in burning power would be increased, the dust in handling and using avoided, and shipments to a distance could be easily made.

Peat ignites easily, requires practically no draught when once the fire has taken hold, gives intense heat, and a banked fire will not burn out nor will it go out until the fuel is consumed. It burns with a flame for some time, and then for a longer period in red hot coals. The gases emitted in the initial stages of burning are not only innocuous but considered by some medicinal, especially against lung troubles. The percentage of ash will vary with the deposit from which the peat is taken. The following analysis was made of samples of compressed fuel made from the product of the Welland bog with the moisture reduced to a suitable amount:

Moisture	12
Volatile matter	58.20
Fixed carbon	26.
Ash	3.80

The absence of soot, clinkers and practically of smoke (when burned under proper conditions) are qualities which will appeal to all classes of consumers. Peat in its crude state varies very much in weight—about 600 lbs. to the cubic yard may be taken as a fair density. The fuel as consolidated by the Dickson press will weigh from slightly under soft coal to slightly over hard coal, neither frost nor a damp atmosphere will affect it, but it should be protected from rain.

The Dickson Press, which is the result of many years patient experimenting, and the expenditure of a large amount of money on the part of the inventor, A. A. Dickson, of Toronto, commends itself by its simplicity. The peat, after being broken to a powder in a breaker, is disposed automatically by gravitation towards the lower and stationary dies or moulds, which consist of two steel tubes about twelve inches long, of uniform bore and open at both ends, into which work two punches. Each charge of peat which flows in when the punch rises is compacted into a solid block on the top of the previously made blocks which occupy the lower two-thirds of the tube, and this column of blocks is forced down a distance equal to the depth of the block made, and thus each time one drops out at the bottom. The resistance thus obtained is yielding, and the formative pressure is always the same. These ideas presented themselves to Mr. Dickson after the failure to press the peat in a closed mould, as this substance offers more resistance and friction in a dry, cold, and disintegrated state than any other natural ligneous substance known; Processes which involve the consolidation of the crude peat in a wet or hot state leave it subject to disintegration upon drying or cooling.

It may be interesting to know that during the past summer factories have been erected at the following places in Ontario: Kirkfield on the Trent Valley Canal, Picton, Perth, Beaverton, Brockville, Galt, Barrie, and on the Ellice marsh north of Stratford, to manufacture compressed peat fuel with Dickson presses. It has been largely an experimental year in many ways. Some of the factories have not yet run, but the fuel placed upon the respective markets in small quantities has been very favorably received, and large factories would be required to meet the evident desire of the public for the fuel. Although much can be accomplished by natural drying in the wind, the question of artificial drying is being speedily and satisfactorily solved, as the Trent Valley Peat Fuel Co. has installed a Cummer Dryer, which promises to render their manufacturing in a much larger degree independent of the weather. There are several other dryers to be installed elsewhere. Although for perhaps several years the fuel will be largely consumed domestically, yet as a steam-rising fuel it has proved its worth unequivocally.

The process of excavating and drying the peat as performed on the Ellice marsh last summer was as follows: Trenches were staked out 3′ 8″ wide, and at intervals two men, side by side, were set digging with the ordinary steel spades with lifting handles. The peat was dug out one spading deep at a time and spread along the bank, when this was dry on one side it was stacked in small stooks of four or five with the wet sides out, three or four pieces on end and one on top. Subsequently these stooks were gathered into larger piles to make way for the spreading of a second spading and so on. To gather in the dry peat, portable tracks were laid over the ditches and the peat thrown into trams carrying from ¾ of a ton to one ton and conveyed to sheds or huge stacks to be thatched with lumber or moss.

The use of dredges and other machinery may reduce the cost of the operations up to this point. The peat will be either taken dry from the shed or dumped wet into the dryer. It will be pulverized before gravitating to the compressing machinery. It will be carried mechanically through all the processes before compression, and also from the machine to the railway car or store-house.

THE TORONTO MUDDLERS BUILD AGAIN.

The people of Toronto are about to spend money in printing the city by-laws. So far as concerns codifying and printing the building by-laws, the money would be better spent in publishing them in the daily papers, so that the people might notice that they are entirely without protection from many of the dangers which threaten the city dweller from the incapacity or crime of those entrusted with building operations, either as owners, architects, or contractors.

We showed, in a former article, that the building regulations of Toronto were a farce, and the office of building inspector a sinecure. The daily papers republished our statements and commented upon them, but no action was taken. The by-laws, which no one knows anything about, and which are entirely inapplicable to present day building, are still supposed to be in force, but in almost all buildings on the business streets these by-laws are entirely ignored.

We will repeat one statement from our former article which shows, as no argument could, the position of affairs: "There are no rules for steel construction in the building regulations of the city of Toronto."

An example of how the building inspector in Toronto guards the public safety is shown by the fact that the city finds its new market building at a standstill, because the steel contractor has refused to erect the roof upon the brick piers provided by the city's architect, and of necessity approved by the building inspector, without whose approval nothing could of course have been done.

If the Dominion Bridge Co., the steel contractors, had gone on with the work, and it had fallen, as they

claim it must, the resulting damages against the city for loss of life would have been very heavy. There can be no doubt that the city is liable for damages to person and property for any accident arising in any way through a cause peculiar to the steel type of building.

If a steel girder in a Toronto building fail, no matter from what cause, the city is responsible because its presence in the building is not in accord with the city by-laws. Such buildings as house the large departmental stores in Toronto are most flagrant violations of the building laws of Toronto.

There are of course, rules for the building of kitchen chimneys, etc., and they are such as the fire underwriters enforce in the farm houses in Muskoka. It is a mistake for the good aldermen of Toronto to build a market; their business ability would find scope rather in growing cabbages which they might vend upon the city hall steps.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

FOURTEENTH ANNUAL MEETING.

The fourteenth annual meeting of the Canadian Society of Civil Engineers opened at the society's rooms, Montreal, on the 31st January.

The president, W. T. Jennings, of Toronto, occupied the chair, and there were present the following members: From Montreal, C. H. McLeod, secretary; Wm. McNab, librarian; H. Irwin, treasurer; J. G. G. Kerry, Geo. Hall, L. J. Marion, C. de B. Leprohon, Percival W. St. George, Frank T. St. George, T. W. Lesage, E. Marceau, E. Fusey, L. S. Pariseau, R. S. Lea, E. C. Amos, Geo. Holland, Alfred Dedman, E. Berryman, E. S. M. Lovelace, Lewis Skaife, R. Forsyth, G. H. Duggan, R. H. Balfour, A. E. Smaill, R. E. Hunter, G. L. Law, F. P. Shearwood, H. A Burson, E. E. Gagnon, E. A. Wallberg, W. J. Sproule, Prof. H. T. Bovey, F. E. Came, Herbert Wallis, J. W. Heckman, E. P. Hannaford, P. A. Peterson, Stuart Howard, W. McLea Walbank, Wm. Kennedy, L. J. Papineau, N. Hanson Greene, Arthur Crumpton, Geo. Janin, John Kennedy, Duncan MacPherson, John R. Barlow, J. S. Vindin, L. A. Desy, Chas. H. Osler, F. L. Wanklyn, Thos. Kirk, J. T. Lemire, R. M. Hannaford, H. B. Stuart, J. S. Costigan, James Ewing, C. S. Leech, Fred Thomson, J. A. U. Beaudry. From Ottawa: Col. W. P. Anderson, Geo. A. Mountain, Wm. Crawford, E. J. Walsh, C. Thomson, A. Campbell, R. F. H. Bruce, C. A. Bigger, Wm. McCarthy. From Toronto, W. T. Jennings, Willis Chipman, C. H. Rust, H. F. Duck, C. J. Crowley, H. W. D. Armstrong. From Quebec, L. A. Vallee, Charles Baillairge, E. A. Hoare, Armitage Rhodes, Thos. Breen, F. X. Berlinguet, Henry O'Sullivan. From Lorette, Owen O'Sullivan. From Brantford, T. Harry Jones, C. A. Waterous. From Berlin, Herbert J. Bowman. From Halifax, C. E. W. Dodwell. From Iroquois, F. R. Wilford. G. J. Desbarats. From Kingston, Prof. W. R. Butler. From Owen Sound, Jas. C. Kennedy. From Coteau Landing, Thos. Monro, Alex. Grant. From Boston, Freeman C. Coffin. From Sault Ste. Marie, Wm. Crawford. From Black Lake, Que., J. S. Costigan. From Valleyfield, J. H. Sullivan.

On calling the meeting to order the president congratulated the society on the large attendance and on the prospects for a good convention. The secretary then read the programme of the meeting, after which the minutes of the last annual meeting were read and confirmed.

The president then nominated Messrs. Howard, Costigan, Stuart, Lovelace, Heckman and Lesage as scrutineers of the ballot for the election of officers. Messrs. Walbank, Berryman and Ewing were appointed scrutineers of the ballot for the Nominating Committee.

A large part of both forenoon and afternoon sessions was taken up by a discussion on the balloting methods of the society, and the greater security of the system from errors in the future. On motion of F. L. Wanklyn, seconded by P. W. St. George, it was decided that in future when more than one ballot is cast, the color, size and all other details of the papers and enclosing envelopes shall be alike; and on motion of J. G. G. Kerry, seconded by C. H. Rust, it was resolved that no list of the ballots cast shall be made before the closing of the ballot, and that no member other than a scrutineer shall be permitted to know who has cast a vote.

REPORT OF COUNCIL.

The following is the substance of the report of council on the work of the society during the past year: The elections in the ordinary course comprised one honorary member, eleven members, twenty-six associate members, four associates, and one hundred and eight students, in all one hundred and fifty. Four associate members have been transferred to the class of member, and thirteen students to the class of associate member. Two members, removed from the roll for non-payment of dues, have been reinstated upon payment of their arrears. The elections under the Quebec Act. Vic. 62, Chap. 32, comprised three members, and fifty associate members. One associate was admitted to the class of member, and thirteen students were admitted to the class of associate member, under the Quebec Act. Resignations have been received from two associates and five students. Three members, four associate members and fifteen students have been removed from the roll for non-payment of dues. The deaths have been: Honorary member—Sir John William Dawson, C.M.G., LL.D., F.R.S. Member— Walter Shanly. Associate—Hugh Ryan. Associate Member—Emery Lafontaine. Students—F. X. Mill and M. A. Bucke. At present the membership stands as follows:

	Non-Res.	Res.	Total.
Honorary members	6	1	7
Members	247	61	308
Associate members	198	91	289
Associates	26	14	40
Students	99	104	203
Total			847

This is an increase over last year of 14 members, 57 associate members, 61 student members, and a decrease in associates of 1, making a total net increase in membership of 131 over last year. There are pending 11 applications for admission. Fourteen ordinary meetings of the society were held during the year, and one special general meeting at which the following resolution was unanimously carried: Moved by C. H. Rust, seconded by J. R. Barlow, "That the council be and is hereby instructed to purchase the property, No. 877 Dorchester street, making use of the Building Fund, amounting to $4,500, for this purpose, and also to raise $6,500 by mortgage on the property, in order to complete the purchase price of $8,000, with an additional sum of $3,000 for repairs and improvements." It was also resolved that the entrance fees, less the examination expenses, be credited to the Building Fund.

Additional subscriptions to the Building Fund were called for by circular, and the following amounts received to date: Subscriptions prior to 1899, $4,656.73; subscriptions received during 1899 and 1900: Collected, $2,084.44; uncollected, $618; total, $3,602.44.

The obligations assumed in connection with the new home are as follows: Purchase price and expenses, $8,011.30; total amount of contracts, $7,475.50; estimated cost of fittings, etc., $755; Architect's fee, $616.25; total, $16,858.05.

In connection with the work of the committees on legislation it was reported that an Act was brought before the Ontario Legislature in the early part of last year, but, owing to opposition, arising chiefly from a misunderstanding of the Act, it was withdrawn after the second reading to be introduced again during the current session. The by-laws under the Quebec Act were sanctioned by Order-in Council on February 24th, 1899. The Board of Examiners, composed of E. Marceau, S. Duval, T. Breen, C. H. McLeod, R. J. Durley and R. S. Lea, held its first meeting, November 7th, in accordance with the Quebec Act, and reported two candidates as having passed the examination for admission to practice.

The Library Committee reported a number of gifts of books and pamphlets from members and friends. Books were given by Angus M. Stewart, A. D. Watson, G. Barnett Smith, F. C. Coffin, A. Crumpton, Gabriel Henry, Wm. McNab and George Brush. Two volumes have been acquired by purchase, viz.,

Railway Track and Trackwork, by E. E. Russell Tratman, and Railway Engineering, by C. B. Smith. Pamphlets and reports on various subjects have been received from A. V. Ramachandra Aiyar, C. Baillairge, C. E. Goad, G. Henry, T. C. Keefer, C.M.G.; John Kennedy, R. Steckel, P. W. St. George, F. M Baker, Wm. R. Hill, H. B. Seaman, W. Murdoch; various exchanges were also effected. The books of the library have been appraised at $3,750, and the library furniture at $1,250. The new quarters will furnish more library accommodation, and enable the committee to carry out many improvements.

FINANCIAL STATEMENT.

The following is an abstract of the receipts and expenses for the year ending 31st December, 1899:

Balance from 31st December, 1898		$ 5,893 22
GENERAL RECEIPTS.		
Subscriptions—		
Arrears	$1,186 00	
Current	2,944 50	
Advance	381 65	
Entrance fees	480 00	
	$4,992 15	
Transactions sold	7 50	
Two dividends on Canada Permanent Loan Company's stock	9 00	
Refund on printing	0 25	
Refund on engraving medal	0 75	
Bank interest on current account	53 85	
Bank interest on deposit receipt	69 03	
	$ 5,141 53	
	$11,034 75	

GENERAL EXPENDITURE.

Part payment for house, No. 877 Dorchester street	$ 3,400 00
Transactions printed and published	712 80
Advance proofs	98 75
Printing, stationery and binding	376 52
Charter, by-laws and list of members	124 00
Postage and post-cards	244 64
Messengers and telegrams	18 26
Cabs, cartage, etc	8 75
Secretary's salary for year	300 00
Assistant secretary's salary for year	480 00
Caretaker's wages for year	144 00
Keeping rooms open at night and Saturday afternoons	118 00
Rent of rooms for year	700 00
Telephone service for year	30 00
Bank commissions on cheques	8 00
Water rates	26 68
Electric lighting for year	72 12
Books, magazines and library expenses	51 30
Expenses re legislation, Quebec province	263 40
Expenses re legislation, Ontario province	225 75
Expenses during annual meeting	83 15
Printing and engrossing diplomas	52 35
Gzowski medal and engraving	7 30
Office furniture and repairs	49 05
Rent of drawer in bank vault for year	5 00
Gas for grate fire	3 10
Part entrance fees transferred to Building Fund	430 00
Treasurer's expenses, car fares, etc	15 00
Petty cash in hands of assistant secretary	7 59
Examiners' fees	50 00
Ice for season	5 00
Insurance on 877 Dorchester St. till Aug. 27th, 1902	25 00
Insurance on present rooms till 18th Sept., 1902	14 40
Builder's risk on 877 Dorchester St. for three months	15 00
	$ 8,104 91
Balance on hand	2,869 84
	$11,034 75

D. MacPherson,
E. Marceau,
Auditors

H. Irwin, Treasurer.

The treasurer's statement of the Building Fund showed assets of $22,250, made up of cash in hand from general fund $2,869, from Building Fund $2,431, arrears of fees and subscriptions to Building Fund about $1,948; value of house, land and improvements, $10,000; books and furniture, $5,000. The expenditure on the house during the year was $6,812. The report was adopted.

The report of the Committee on Legislation was presented by Willis Chipman, as follows:

The Committee upon Legislation appointed at the last annual meeting of the society to promote the passage of an Act respecting civil engineers, a draft of which was laid before the society at the last annual meeting, begs to report as follows: Several meetings of the committee were held in January, February and March of 1899, and several conferences were held with the Minister of Education of Ontario and our solicitors, the result being Bill No. 136. The bill was introduced into the House as a private measure, and the fee ($100), paid. The Bill was referred to the Private Bills Committee two or three days before the House prorogued, and was referred back by the committee. The bill was opposed by Prof. Harris, of Queen's, and by Mr. Bell, secretary of the Canadian Mining Institute The Government refunded the committee the $100 deposited when the application was made for introducing the bill. The committee has held two meetings during this month, and has gone carefully over the bill of last year, making some alterations that should remove the opposition from the members of the Mining Institute and mechanics.

The president observed that the opposition in Ontario was largely due to popular ignorance of what the society's aims were. Some of the labor organizations were under the apprehension that the society was opposing their interests; but when they see that this society will prove a help and not a hindrance to the legitimate aims of all labor organizations, whether skilled or unskilled, they will no longer oppose it.

Mr. Chipman said it must not be supposed that because the committee had not accomplished much they had been idle. Legislation of this kind was slower of accomplishment in Ontario than in Quebec, and the work of last session had at least disclosed where the opposition lay. Ottawa and Kingston had both been centres of opposition; in the latter case from an ex-professor of the Military College. Whether there would be time to organize our forces for the pending session of the Ontario legislature was a question.

The committee on the Gzowski medal reported that no award had yet been made, and the matter was left with the council.

Mr. Sproule stated that the committee on titles of engineers was not ready to report and asked that the committee be continued.

The committee appointed to investigate the complaint of Henry A. Gray that his paper on the lake levels had not been printed in the transactions of the society, reported to the effect that that gentleman had made considerable use of extracts from the reports of the American Government engineers and other authorities without giving credit or using quotation marks, and that such omissions had justified the editorial committee in withholding the paper from the transactions; but the committee recognized that Mr. Gray's paper contained a great deal of valuable information on the lake levels that was not accessible to members of the society, and recommended that, if he would indicate the extracts by quotation marks and give credit to the authorities to whom he was indebted, the paper be printed in the transactions. The report was accepted and the council was instructed to communicate with Mr. Gray.

After adjournment at noon Mr. Kerry reported on behalf of the committee on "Fees" appointed to investigate the question as to whether city members obtained more than their fair share of the benefits of the society. The committee, composed of Messrs. Irwin, Howard, McLeod and Kerry went over the treasurer's statements for the past five years and selected from them all expenditures which are at all of a local character. These are: Rent, janitor, night librarian, water, gas, telephone, electric light and meetings. It is not easy to say what portions of these expenditures would have to be made by the society for the conduct of its general business if it had no local membership, but in such case the expenses of a head office

and library would probably be at least $500. Deducting this sum from the totals of the items above noted the following are the local expenditures, and the income from the extra fees paid by resident members and associate members for the years under consideration:

	Fees Received.	Expenditure.
1895	$162	$256
1896	166	267
1897	176	292
1898	276	552
1899	304	599

The increase in expenditure in the last two years was due to renting an extra room and to the opening of the rooms at night. It would appear from these figures that the local fees do not fully meet the local expenditure as figured out on the above basis, but that basis is itself only an estimate, and on the other hand no value can be placed upon the service rendered by the local membership to the society in general in conducting much of its business and keeping alive its meetings and committees, duties which in some cases have become so arduous that the society must shortly expect to place paid assistants at the disposal of the treasurer and librarian. The letters which caused the appointment of the committee seem to have been written under a fear that with the opening of the new society house, the local expenses would greatly increase, but it does not appear to your committee that any expenditure upon the furnishing and maintenance of the house which may tend to advance the dignity and standing of the society as a professional society ought to be opposed by any member, whether resident or non-resident. On the other hand your committee feel that any expenditures which are not proper to a society constituted solely for professional purposes, but belong rather to the province of an engineers' club, should not be chargeable to the general funds, and would, if permitted by the council, furnish valid ground of complaint to all members not benefiting by such expenditures. Your committee would suggest that this report be made a subject of discussion at the annual meeting, as it does not feel that the committee itself is sufficiently representative to make any recommendation based on the facts above presented.

Mr. Kerry added that local members had to pay an extra fee of $2 for the more frequent use they were supposed to have of the rooms. He said the policy of the society was to become the general engineering society of Canada, and nothing could be more injurious than to spend money in a way to bring no benefit to members outside the city. The library was a necessity, and we should have the best equipment in this respect that it was possible to get, but the general society should not be taxed for the pleasures of a club for the advantage of local members. During the discussion reference was made to a card room used by local members. The president and Mr. Peterson expressed surprise that a card room existed, and hoped that this feature of the rooms would be done away with at once, otherwise the local membership of the society would degenerate into a club.

Mr. Dodwell, speaking as an outside member, thought the society should not begrudge the cost of proper quarters. He had not been here for two years, and might not be here for another two years, but he was quite willing to pay his share of the cost of maintaining a proper home for the society.

Mr. St. George said it was the intention in the new quarters to provide sleeping accommodation for two; this was for outside members, who might prefer to lodge at the society's rooms instead of going to an expensive hotel. After further discussion the following resolution was passed on motion of Mr Sproule seconded by Mr. Kerry: That no expenditures from the society's funds shall be incurred either in purchases or maintenance, which are not necessary to the carrying on of the business of the society as a whole, and in the direct interests of the general membership, and that this resolution be transmitted to the council as the expression of the annual meeting.

The president made a feeling reference to the deaths of Sir William Dawson and Walter Shanly as old and highly honored members of the society, and it was decided to send formal resolutions of condolence with the families of the deceased, and of other members who had passed away during the year.

The secretary read the results of the circular post-cards, which had been sent out soliciting the opinion of members as to future conventions. The following was the list of questions, and the total number of answers for and against:

1. Are you in favor of continuing the present arrangement of holding the annual meeting in Montreal in January of each year?—Yes, 95; no, 103.

2. Shall the society hold a summer convention at different places each year?—Yes, 177; no, 19.

3. If in favor of summer convention, in what month should it be held? Of the total answers 28 were in favor of June, 25 of July, 36 of August and 32 of September.

4. If such convention is held should the annual meeting be at the same time and place?—Yes, 119; no, 70.

It was moved by W. J. Sproule and seconded simultaneously by L. S. Pariseau, Duncan MacPherson and T. Harry Jones, that $200 of the society's funds be devoted to the National Patriotic Fund. This was carried by a standing vote, the members singing "God Save the Queen."

The scrutineers for the nominating committee reported that the following had been chosen for this work:

Quebec—L. G. Papineau and C. de B. Leprohon.

Ontario—C. H. Rust, J. Galbraith and Geo. A. Mountain.

Manitoba and N.W.T.—Col. H. N. Ruttan.

Maritime Provinces—Dr. Martin Murphy.

Newfoundland and Foreign—Lewis Skaife. Messrs. W. T. Jennings, W. G. McN. Thompson and T. C. Keefer, the three last presidents, are ex-officio members of the committee.

President Jennings then delivered his annual address as follows:

On retiring from office I take this opportunity of again thanking the society for the high honor conferred in electing me to the presidential chair, and to express regret at my inability to have given the duties of the office the full attention they demanded. However, if not frequently in attendance, I have had the society and its objects fully in mind, and my constant desire has been to see the society attain a position where from its standing and activity in the advancement of scientific education, coupled with wise regulations and a high standard of ethics, it will command the hearty support of engineers in all branches of the profession, and also the respect of the public at large.

Referring to our inception, formation and advancement, I may briefly remind you that the society was established by a Dominion Government charter early in 1887 "for the object and purpose of facilitating the acquirement and interchange of professional knowledge among its members, and more particularly to promote the acquisition of that species of knowledge which has special reference to the profession of civil engineering, and, further, to encourage investigation in connection with all branches and departments of knowledge connected with the profession." The society was also empowered "to acquire and hold all land and property necessary and requisite in order to carry out the objects and purpose for which incorporation was sought." The numerical strength of the society during the first year (1887), was as follows: 188 members, 45 associate members, 10 associates, 83 students; in all 335 members. During the same year the sum of $2,480.77 was paid in to the treasurer, principally on account of annual subscriptions.

From the secretary's returns it appears that the membership for 1899 numbered as follows: 7 honorary members, 308 members, 289 associate members, 40 associates, 203 students; in all a total of 847 members, and showing a total net increase since the year of the formation of the society of 512 members of all grades, while the receipts from entrance and annual fees, etc., amounted to $5,141.53. This sum, added to the amount of $5,893.22, brought forward from general fund account, makes a total credit balance at the end of 1899 of $11,034.75, which sum has, as you will notice in the treasurer's statement, been largely drawn upon for building account.

Permanent withdrawals from membership have been few, and due in most instances to removal from the country. Removals by death have cost us many worthy members, among whom we sincerely regret, Sir John William Dawson, C.M.G., LL.D., and two past presidents, namely, Mr. Samuel Keefer and Sir Casimir Gzowski. Mr. Walter Shanly may also be included in the number of past-presidents, as he was on several

occasions offered the nomination, but invariably declined. As is well-known, these gentlemen were of the highest professional and social standing, and heartily entered into the scheme for the formation of the society, and did their part nobly to advance all its interests from the date of its formation up to the time of their decease. Others have departed who, although perhaps not as prominent before the public and in our midst, acquitted themselves honorably in the profession and faithfully as members.

The society, having carried out the second provision in its charter, is now to be congratulated on the acquisition of its own premises (as referred to in the treasurer's report), at a total estimated cost for improvements, etc., $8,846.75; building and land, $8,011.30; total, $16,858.05. Of this amount there has been obtained by special subscriptions from members and friends the sum of $8,259.17. The balance of $8,598.88 has been temporarily provided for by loan from the general funds of the society.

It is confidently hoped that monetary aid sufficient to extinguish the whole building account item of $16,858.05 will be secured, thereby enabling the society to apply moneys now temporarily loaned from the general funds to other useful purposes, notably the enlargement of the reference library, which is now valued at $3,750, or, with furniture and fittings at a total of, say, $5,000, all of which can be inexpensively removed to our own premises, which it is hoped will be ready for occupation by the 1st of May next. The benefit to be derived from having one's own professional home will doubtless strike every member as the beau ideal of seclusion and comfort. We now know that we have a headquarters, where we can meet and discuss topics of professional interest, or where we may individually rest by times when here. It has been stated by some of our members that the establishment has involved too great an expenditure, and that only local members would profit by it. I would remind these gentlemen, that, as before stated, a large proportion of the cost was subscribed by members and friends for this particular purpose, which the society has had in contemplation from the outset.

I am satisfied we will do more individually and collectively in this way in the near future, and that we will doubtless soon have the pleasing duty of determining whether our surplus funds are to be devoted to the wider distribution of engineering information beyond that emanating from papers by our own members, or expend it in additions to our reference library, or, finally, stop the accumulation of funds by decreasing the annual subscription fee. I cannot think that the latter course would meet with the general sanction of the members, because, as time wears on, coupled with the general growth of the country, an ever-increasing demand will make it imperative that our members be promptly informed of the latest engineering advances. However, as we have not yet reached that stage, it is unnecessary to further enlarge on the subject, and I only mention the matter as food for thought and discussion later on.

As to the second part of the assertion, that only local members would really profit by the establishment of our home, I may say that such must necessarily be to some extent the case, and we who are not at headquarters can only hope that those who are so fortunately situated will take full advantage of the opportunities afforded. Members should look on this feature in a broad light, and recognize that, while distant from the home, yet the advantages of it are apparent, in that the library is open to us should we at any time desire information as recorded in our reference volumes, by simply making application to the secretary for the loan of the required work, which, if too voluminous to transmit, and the subject matter required not too extensive, there is no reason why arrangements should not be made for its transcription and transmission to the applicant. In this and many other ways can the "home" be made a bond of usefulness to the members of the society, while its firm establishment means that the Canadian Society of Engineers has become a permanent and fully recognized institution of the country.

The advancement of economic mining has had the effect of attracting experienced mining engineers to the country, and of inducing a large number of students to take up that branch of the profession, with the result that a separate society, called the Canadian Mining Institute, has been successfully formed, and, as it is desirable that all branches of engineering should be embraced in the Canadian Society of Engineers, it is hoped that this valuable branch will be united with us in the near future.

Acknowledgment as a corporate body has been obtained from the Legislatures of the provinces of Quebec and Manitoba. An effort has been made in the same direction in the province of Ontario, but so far without success. It is, however, hoped that substantial advancement will be made in this respect during the coming session of the Ontario Legislature, and it is not difficult to see that the carrying out of the provisions in our bill will not only benefit the profession and the operative, but also assist all intelligent and well-disposed persons by the elevation of the educational standard and general proficiency of the civil engineering profession of this country. In connection with our desire for provincial incorporation, it has been stated, by those opposed to the measure, that our common object is to thoroughly entrench ourselves behind the Act in order that we may the more successfully wage war on those now practicing who have not thought fit to ally themselves with the society; also to legally enable us to exact enhanced fees for services, and generally to place a curb on free and untrammelled labor, be it professional or otherwise.

In reply to this and other like statements, I would briefly point out that the old days of casual study as a pupil principally carried out in the office, field or on works, and generally based on theoretical education of a more or less complete character, are almost past and gone, and while recognizing and upholding many good features in the old system, yet the near future will find only men in the profession who are graduates of schools of engineering or of this society.

Therefore (while not wishing to interfere with any one now engaged), the society seeks incorporation (in the provinces) particularly for the purpose of placing the foot of the student firmly on the first rung of the ladder by insisting that he shall have the foundation work of his profession securely laid in the form of a good academical education, and that his further ascent may be made under the guidance of experienced engineers, whose duty it will be to encourage him, until time and experience in actual service enable him to become a full corporate member, and competent to stand alone and unaided.

In the matter of fees for professional services, the society has not made special provision, and it is desirable that a plan be formulated whereby satisfaction and uniformity may be obtained in this respect, as is customary in other professions.

When one thinks of the duties and responsibilities vested in an executive engineer, in charge of extensive and costly works, and often acting in a judicial capacity as between Governments, companies or municipalities, as against each other or contractors, and compares the returns they receive with those obtained by our judges and leaders in mercantile pursuits, we certainly cannot be charged with placing a high estimate on ourselves.

As to interference with skilled or ordinary labor, I hold that the reverse is the case, as by the better and more systematic education of our engineers we create a competent force to guide and assist skilled artizans and mechanics, in advancing their interests, either as inventors, operators or overseers, of the laboring masses, who thereby cannot fail to obtain improved conditions.

As an index of this feature, it is only necessary to point to the valuable assistance rendered by schools of technology in Europe, and on this continent, where the ordinary mechanic may, by evening study under engineers, chemists and other suitable professors, secure for a trifling sum such knowledge of a scientific character as will enable him the more clearly and effectively to study out and improve upon present machinery and methods of manufacture, and generally bring under the control of the hand of man the powers and material of the physical world.

The ethical principles which should be observed between members are not difficult to determine, and may be summed up in the tenets of the "Golden Rule," and are largely provided for in our by-laws. It has, however, been suggested that members enjoying permanent positions, and whose compensation is in consideration of the occupation of their whole time, should discontinue outside professional practice in so far as the interests of the country or municipality will permit.

It is to be hoped that the "transactions" of the society will

be increased in volume by the addition of articles other than those emanating from members of our own society.

I have thus briefly touched upon society matters rather than those of a specifically engineering character, as has been the custom heretofore by retiring presidents, feeling that at this time, when we are entering upon a new and more extended era, it would appear advisable that our members should be reminded of the objects of the society, and of the duties and obligations of its members to the public, and to each other in order that we may the more fully understand our position.

In concluding, I can only express a hope that our efforts will continue to meet with success, and that each member will personally feel that the society is of real value, and of benefit to our country.

On motion of P. A. Peterson, seconded by Thomas Monro, the thanks of the society were tendered to the president, who, in his suggestive and instructive address had taken an entirely new line of thought in presidential addresses.

John Kennedy, who had been moved to the chair, complimented the president on the practical features of his remarks. The address would prove not only helpful to members, but to the general public, who might wish to know the aims and purposes of this society.

The election of officers for the ensuing year resulted as follows:

President—H. T. Bovey.

Vice-Presidents—G. H. Duggan, Percival W. St. George and E. H. Keating.

Secretary—C. H. McLeod.

Treasurer—H. Irwin.

Librarian—E. A. Rhys-Roberts.

The Council (the returns for which could not be presented till after the meeting), was as follows: John Kennedy, C. H. Rust, Thos. Monro, G. A. Mountain, Duncan McPherson, T. H. Tracy, St. George Boswell, James Ross, E. Marceau, H. Wallis, Prof. J. Galbraith, R. Hering, J. M. McCarthy, W. McNab and C. E. W. Dodwell.

Prof. Bovey in thanking the society for electing him to the presidency, said he had not sought the position, but was, in fact, in England when he was nominated. He therefore felt the honor to be all the greater, and would do his best to show that it was merited.

On motion of Herbert Wallace, seconded by Stuart Howard, a hearty vote of thanks was tendered to Mr. Jennings for his services as president during the past year.

The meeting for business then adjourned till Feb. 6, when the returns of the scrutineers for members of the council, as given above, were received.

After the business of the day the members to the number of sixty or seventy left by special train, placed at their disposal by the Grand Trunk, for Boston. Owing to press of other matter an account of the visit is held over till next issue. One of the events of the trip was the annual dinner, a report of which follows:

THE ANNUAL DINNER.

The annual dinner of the society was held at the Hotel Brunswick, Boston, and proved an occasion to be remembered by all who attended.

The chair was occupied by the president-elect, Prof. H. T. Bovey, Dean of the Applied Science Faculty of McGill University, who had on his right C. Frank Allen, professor of railway engineering in the Massachusetts Institute of Technology and president of the Boston Society of Civil Engineers, and on his left, Desmond Fitzgerald of Brookline, late president of American Society of Civil Engineers, and engineer of the Sudbury Department of the Metropolitan Water Board.

Among the members and guests of the society present were: Leonard Metcalf, S. E. Tinkham, Henry Manley, H. Bissell, Prof. Geo. F. Swain, Howard A Carson, Frederic P Stearns, John E Cheney, E. W. Howe, Prof Gaetano Lanza, L. F. Rice, Chas. W. Sherman, Geo A. Kimball, A B. Corthell, W W. Cummings and I J. Hirt, of Boston; W. E. McClintock, of Chelsea, Mass.; Prof Ira N Hollis and Prof D L. Turner, of Cambridge, Mass.; T Howard Barnes, of Medford, Mass.; Alex H French, of Brookline; Geo. B. Francis, of Providence, R I; Prof C. H McLeod, Duncan MacPherson, Stuart Howard, John Kennedy Percival W. St George, J A. U. Beaudry, Fred. Thomson, A. E. Smaill, R. H. Balfour, H. Rutherford, T. H. White, F. L. Fellowes, Alex. Pringle, E. C. Amos, L. G. Papineau, Lewis Skaife, T. W. Lesage, J. S. Vindin, Wm. McNab, F. P. Shearwood, R. E. Hunter, Gordon Grant, F. E. Came, Joseph W. Heckman, Alex. J. Grant, Arthur Crumpton, R. S. Lea, Sidney Hosmer, of Montreal; C. H. Rust, H. W. D. Armstrong, E. B. Biggar, of Toronto; Charles Baillairge, Louis A. Vallee, Armitage Rhodes, F. X. Berlinguet, Henry O'Sullivan, of Quebec; C. Thomson, A. Campbell, Col. W. P. Anderson, Chas. A. Bigger, of Ottawa; C. E. W. Dodwell, of Halifax, N.S.; Prof. W. R. Butler, C. B. O. Symons, of Kingston; T. Harry Jones, C. A. Waterous, of Brantford; G. J. Desbarats, F. R. Wilford, Iroquois, Ont.; Herbert J. Bowman, Berlin, Ont.; Wm. Crawford, of Sault Ste. Marie, Ont.; Owen O'Sullivan, of Lorette, Que.; Chas. J. Crowley, of Chaudiere, Que., and J. H. Sullivan, of Valleyfield, Que.

Among the invited guests who were unable to be present were, Messrs. Charles M. Hays, general manager Grand Trunk Railway; F. H. McGuigan, E. H. Fitzhugh, G. B. Reeves, W. E. Davis and F. W. Morse, of the Grand Trunk Railway; T. A. McKinnon and Lucius M. Tuttle, of the Boston and Main system; W. A. Ritchie, of the Pullman Palace Car Co.; J. F. Wallace, president, and C. W. Hunt, secretary, of American Society of Civil Engineers; Wm. Jackson, city engineer of Boston, H. M. Whitney, president Dominion Coal Co.; J. E. Hardman, president, and B. T. A. Bell, secretary, of the Canadian Mining Institute, and Prof. S. H. Capper, president Quebec Association of Architects.

After full justice had been done to an excellent dinner the chairman proposed the "Queen," and in doing so expressed his regret that the last days of our beloved Queen should be distressed by the horrors of war, but there was one consolation for the sufferings of the South African war, and that was that it had manifested the solidarity of all parts of the British Empire, and it was bringing about the solution of more than one of the problems of that Empire. After the toast had been duly honored, Prof. Bovey proposed the "President of the United States." He said the imaginary line between Canada and the United States marked no division in the hearts of the people who, though they might criticize each other in a friendly way, realized there was a kinship in sentiment as well as in blood. He never came to Boston without feeling loth to go away, and without carrying in mind some happy reminiscences of his visit. He hoped the Boston society would return this visit, and so increase those good relations which should subsist between kindred societies. The "Star Spangled Banner" was then sung, followed by "He's a Jolly Good Fellow."

"The Engineering Profession" was briefly responded to by C. H. Rust, city engineer of Toronto, who after returning hearty thanks said he wished to give place to L. J. Hirt, of the N. E. Gas and Coke Co. Mr. Hirt said Boston was practically the pioneer American city in developing the electric railway, having in the course of that development changed the types of motors five times. Boston was also one of the most advanced cities in solving problems of water supply and sewage, and owing to the number of rivers the difficulty of these problems had been increased. In the case of their own gas works they had to tunnel under the river, the work being done by compressed air. The iron pipe was laid concentrically in a wooden tube, and one of the unforeseen difficulties after the tunnel was finished was the sweating of the iron pipe. In the main pipe under the river this sweating amounted to six or seven barrels of water per day. In concluding Mr. Hirt laid stress on the value of practical and technical education; and spoke in high praise of the value of Nova Scotia coal in the work carried on by the company he was connected with.

With this toast the chairman particularly associated the names of Desmond Fitzgerald, late president of the American Society of Civil Engineers; Prof. Hollis, of Harvard University, and Prof. Lanza, of the Massachusetts Institute of Technology. Mr Fitzgerald in thanking the chairman for his kind words said he felt all engineers were brothers, no matter to what part of the continent they belonged. He loved Canada, because he had often fished her rivers, climbed her grand mountains and explored her forests; but he never loved her as he did now. The Canadian Society of Civil Engineers was an honor to the pro-

fession, and he was surprised to learn that it now numbered 800 members. This fact showed the enormous development of the material resources of Canada. He spoke of the fine physique of Canadians, and remarked that when introduced to the first member he had to look up in the air to see his face. Engineering was the noblest of the professions, not even excepting law, divinity or medicine; for engineering was founded on horse sense, and this was the requisite of all. The engineer was the great unifier of the human race, for his work joined country to country, brought health to cities in pure water supplies, spanned the widest rivers and bridged the ocean itself by the steamship lines, which joined continent to continent. Mr. Fitzgerald's speech was enlivened with gleams of real Yankee humor, and was warmly received. Mr. McNab then gave a capital recitation from Dr. Drummond describing how Batisse came home from his sojourn in the States, and was followed by Prof. Hollis, of Harvard University, who said he was glad to meet the members of the Canadian Society of Civil Engineers at dinner, and to renew in this meeting the pleasant memories of his visit to Montreal under their auspices several years ago. It was to be hoped that this visit was only the beginning of many others, and that we may become neighbors indeed. Speaking to the toast he thought the words of an old friend would be very apt in this connection. This friend said, "Your profession bids fair to become the great profession of civilized nations. It provides for the homes, the material welfare, and the general well being of all people. The engineer will surely cure the tariff more effectively than the legislator, because he will by his labor saving machinery make tariffs unnecessary, and bring us to free trade." It struck the speaker that his function in modern times is far wider even than this. Mr. Fitzgerald had spoken of the railroads. Have we ever thought that the railroad system is more important in uniting the Atlantic and Pacific coasts of this continent than even a constitution framed by the people who live here? The States are bound together far more effectively by the steel rail and the telegraph wire than they could ever have been by written agreement. The Canadian Pacific is doing for Canada just what the Union Pacific has done for the United States. In contrast to the railroads in this country we have the necessity of marine transportation to Great Britain and her empire. The striking changes which have been effected by the engineer are seen in the readiness with which your country transports to South Africa an army of 200,000 men with their equipment, artillery and horses. This is almost beyond imagination—six thousand miles by sea made possible by the constructors of ships and machinery. It is no exaggeration to say, therefore, that the British Empire, or better still, its vast confederation of colonies, can be held together by means of the sub-marine cable and the steamships. It is this thought that should make us all proud of our profession and glad to belong to it. The presence in Boston at this time of the Canadian Society impressed him strongly with feelings of deepest sympathy for British people in the trials which war has brought upon them. He held by the English, as he believed that their cause is the cause of the Anglo-Saxon race, which stands as the great bulwark of civilization and individual freedom. He was sure that he spoke the thoughts of thousands of his countrymen when he expressed the deepest grief for our losses and the most heartfelt sympathy for us in this trouble. He for one followed the course of the war from day to day with the same interest and sympathy as he did two years ago that of their own war in Cuba. Time and acquaintance have brought England and America together. In Cambridge, four miles from here, he lived not far from a milestone marked "Eight miles to Boston." It was put up when this was an English colony, and the journey from Cambridge to Boston was made through Charlestown, and by ferry across the Charles River. We have many of the old colonial customs and institutions in Cambridge, and we cherish much of the old affection for English soil. No wonder then that we are drawn together at this time of trial to your people. Concluding, he hoped the two societies would soon meet again. Prof. Hollis' speech was received with much enthusiasm. Prof. Lanza on being called on said it was hard to believe Prof. Bovey was not a Yankee. He emphasized the unity of the two peoples. Referring to the toast he said the day was now past when law, divinity and medicine could monopolize the culture of the country. The great object of the professions was the best good for man, and the engineering profession stood for absolute truth, therefore, it must stand as the science of all sciences. With this great aim the engineer did not stop to consider party, and was not tied within the boundaries of a country, but aimed for truth and the good of man in general. He remembered how royally the American Society of Mechanical Engineers was welcomed in Montreal some years ago, and was glad such visits as these made the ties between the two peoples closer as time went on. After the singing of "Soldiers of the Queen," by Stuart Howard, of Montreal, F. P. Stearns, chief engineer of the Metropolitan waterworks, was called on and spoke of the work done by the State Commissions appointed by Massachusetts to deal with the water supply of cities and with the liquor traffic. The work of these commissions had been most satisfactory to the public, because the appointments had been kept out of politics, having been made by the governors, who had fortunately been able and upright men.

John Kennedy, harbor engineer, Montreal, then proposed the "Boston Society of Civil Engineers," and spoke in high praise of the hospitality of the Boston engineers, whose thoughtful attentions to the Canadian visitors had delighted them all. He was much struck by the evidences of strength and prosperity shown by the Boston society, which now numbered 500 members, many of whom took such high rank in the profession in the United States. Boston was not only a pioneer in the development of electric lighting and the electric railway, but was to the front in dry docks and other harbor works. These advances were due to the able work of engineers, and he heartily wished every success to the Boston society.

Three hearty cheers were then given for the Boston society, and Lewis Skaife followed with the song "The Absent-Minded Beggar," to which he added the following original topical verses:

When you've feasted at the Brunswick, when you've kept it up o' nights,
When you've dined and wined the Boston engineers,
When you've swung around the circle and have seen the Boston sights,
And have listened to the wisdom of the seers,
You'll be absent-minded beggars for a day or two at least,
And your wits will have a tendency to leave you,
So you'd better stay in Boston with the wise men of the East,
Who have done a lot o' little things to please you,
You stay, I'll stay—stay till we sober down,
Montreal can wait for us till some other day,
Each of us doing our country's work surveying this Boston town,
We've found the service pleasant, and we'll stay, stay, stay.

Some day they'll come to see us, these same Boston engineers,
And we'll find a way to keep them when they come,
We'll dine them at the Windsor and we'll drink the cup that cheers,
And we'll make them feel exceedingly at home.
We will build a solid highway from St Lawrence to the Bay,
We'll be brothers in behavior as in blood,
We will join in an alliance that will never pass away,
And we'll face the world together for its good.
We'll join, they'll join, allies forevermore,
A hundred million freeborn men here and over the sea,
Each of us helping the common cause (and this shall our motto be)
Liberty, fraternity, and the world as it ought to be.

Prof. C. Frank Allen replied to the toast, saying it seemed queer for himself and members of the Boston society to be playing the part of guests in their own city, and the situation seemed to show that it was more blessed to give than receive. He spoke of the intimate and pleasant relations of the men of Boston and Montreal, an intimacy that had largely been brought about by the work of engineers, starting with Stephenson, whose achievement in building the great Victoria bridge had opened up direct railway communication between Boston and Montreal. He had not thought it possible to get as much enjoyment out of the visit of the Canadians as he had got, and he hoped this would not be their last visit.

Mr. O'Sullivan, chief of surveys of Quebec, after referring to his very pleasant trips to Boston, the first having been made in 1856, gave a comic song, "The Old Irish Stew" to the tune of the "Red, White and Blue," which was sung with a rousing chorus.

Howard A. Carson, engineer of the subway, was called on and in a thoughtful speech referred to the imaginative faculty of the engineer, who must have in his mind a conception of the structure or work he sets himself to do before it exists in fact. The imagination must of course be bound by the laws of nature, or the engineer would find himself as disappointed a man as the southerner who recently conceived the

idea of setting monkeys to pick cotton. Judging from the deftness of monkeys he thought he could revolutionize cotton picking, as one man might look after 20 monkeys, who could pick ten times as fast as the human cotton picker; but when he got to work he found it took about 20 men to look after one monkey, and the problem baffled him. He predicted that the work of the engineer would obliterate tariff walls, and while we might have our local governments and institutions, we did not want to have any fellow looking into our trunks when we crossed a boundary, but we wanted our horses, our timber, our coal and other products freely exchanged between the two countries.

Prof. Swain, of the Massachusetts Institute of Technology, also spoke of the satisfaction it gave him to know that the Canadian society had chosen Boston as the objective of their excursion. The ties between Canadians and Americans were growing, and they have never been so strong as they are at the present time.

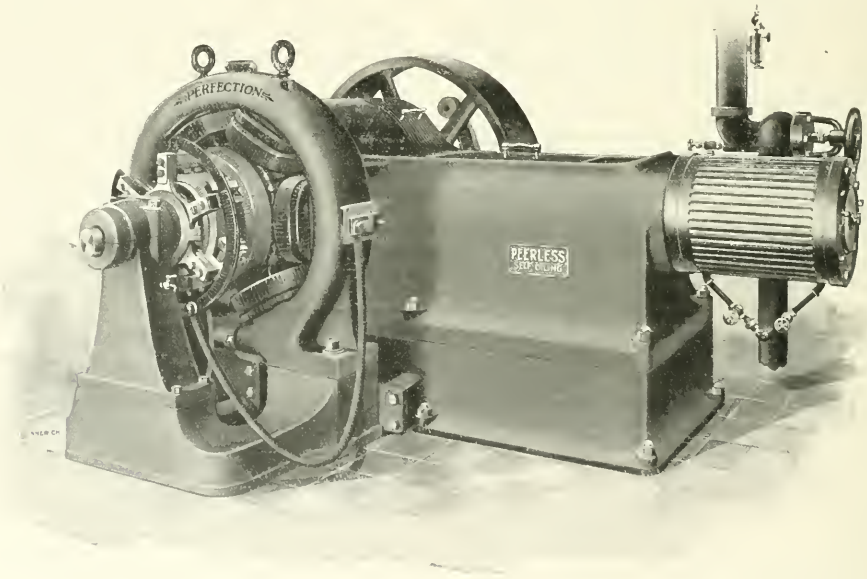
Mr. Dodwell, of Halifax, then sang "In Cellars Cool," and in response to an encore gave "Simon the Cellarer."

Prof. McLeod, of McGill University, was called on to reply to the toast of "Our Society." Briefly returning thanks he laid down for himself the law that as secretary of the society his work was to do and not to talk.

THEELECTRIC LIGHTING AND POWER PLANT OF VICTORIA HOSPITAL, LONDON, ONT.

One of the most efficient electrical equipments installed during last season was that of the Victoria Hospital at London, Ont. A rigid specification was prepared by the Gilbert Wilkes Engineering Co., of Detroit, under whose supervision the work was installed and tested. The plant, consisting of two direct connected engines and generators of 43 h.p. and 32 k.w. capacity, respectively, were to be of noiseless operation, to have a regulation within two per cent. limit, and a capability of being overloaded to twenty-five per cent. for several hours without injury. The contract was secured by the Electrical Construction Co., of London, Ltd., who have installed the entire plant, which has been in use now about five months, giving the very best of satisfaction.

Being a duplicate plant it has been customary for the engineer-in-charge to run each unit for twenty-four hours alternately with the other, as light and power are required continuously throughout the building. However, beginning with 17th February, one of the generating sets was started on a 7-day continuous run night and day, at the end of which temperatures were taken showing the following temperature rise of the different parts above the surrounding atmosphere: Commutator,



DIRECT CONNECTED ENGINE AND GENERATOR, INSTALLED AT VICTORIA HOSPITAL, LONDON, BY THE ELECTRICAL CONSTRUCTION COMPANY OF LONDON, LIMITED, AND E. LEONARD, ENGINEERS, LONDON, ONT.

Charles Baillairge, consulting engineer of Quebec city, was also called on and compared the work of the engineer with other professions, with the conclusion that engineering was the head of all professions. A general had to look at things around and facts that were visible, but an engineer had to look into and through things, and to draw inferences from things that were not visible or but dimly known. When one looked about him he would see that all the comforts of modern life were due to the skill of the engineer.

Prof. Bovey here proposed the health of Mr. Metcalf, who had personally done so much for the visitors, and the toast was drunk with "He's all right."

"The Ladies" were remembered in a humorous speech by Col. Francis, resident engineer of the N. Y., N. H. and Hartford Railway, and by T. H. White, of Montreal.

Before separating the president reminded the company of the forthcoming convention of the American Society of Civil Engineers, to be held this year in England, and he hoped not only that the attendance of Americans would be large but that many Canadians would join.

11° C.; armature core, 17° C.; crank pin journal, 17° C.; left bearing of engine, 13° C.; right bearing of engine, 11° C.; oil of engine, 16° C.; field coils of dynamo, 9° C. Considering that a limit is allowed in general engineering practice of 40° C., and sometimes 50° C., the above figures are exceptionally satisfactory. During the week the load had varied between ten per cent. overload and one fifth of full load, no adjustment of the brushes being necessary nor was any special attention required.

The engines which are supplied by E. Leonard & Son, of London, are of their new Peerless self-oiling type, and are lubricated automatically in all parts without attention. Renown engine oil being used for all bearings, and Capital Renown for the cylinder. A description of the principal features of this new engine, which is having a large sale, was given in our December number.

The equipment is electrically controlled by means of a handsome Tennessee marble switch board, provided with ten light circuit switches, five motor circuit switches, main switches, pilot lights and rheostats, etc., making a very compact and well arranged board. The plant also furnishes power for two direct

connected elevator equipments installed by Malloch & Co., of London. The electric motors and controllers of which were furnished by the Electrical Construction Co., of London, Ltd., who also installed two motors direct belted to fans, which are used to exhaust the air from the entire building. The fan motors are of the bi-polar type, and have a speed controller. The smooth running of the engines, and the steadiness of the voltage of the electric plant, have called forth high compliments from the many visitors to the new institution. The engineer and mechanical superintendent is Samuel S. Glass.

THE ENGINEERS' CLUB, TORONTO.

The annual dinner of the Engineers' Club of Toronto, took place at the Rossin House, Toronto, February 8th, and the following gentlemen were elected to the various offices for the ensuing year: President, Kivas Tully; vice-president, Prof. Jno. Galbraith; directors, C. H. Rust, representing the civil engineers; R. W. King, the mechanical engineers, and T. R. Rosebrugh, the electrical engineers; treasurer, T. B. Speight; secretary, Willis Chipman. Among the members who participated in the annual dinner at the close of the business meeting were the following: Kivas Tully, C. M. Canniff, C. E. Cooper, — Brodie, W. A. Clement, Henry F. Duck, Jno. A. Duff, Fred. G. Durnford, J. A. Ellis, W. A. Johnson, Henry A. Gray, — Gordon, Jno. Galbraith, G. H. Hanning, R. W. King, E. H. Keating, Geo. R. Mickle, J. G. Maybee, E. Phillip, Rod. J. Parke, Jno. G. Ridout, C. H. Rust, T. S. Scott, T. B. Speight, R. T. Tate, Geo. White Fraser, Jno. Williams, C. H. Wright and P. M. Wickens. The usual toasts, with music, concluded a very successful entertainment.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.

PRODUCTS OF COAL.

The monthly open meeting of the Hamilton Branch of Stationary Engineers was held February 20th. The principal feature of the evening was an address by J. M. Williams of J. Winer & Co., on the subject of products that could be obtained from coal. The address was illustrated throughout by means of blackboard drawings, and specimens of the various substances named were on exhibition for the inspection of the members present. It was demonstrated that after the first product, which was heat, the next two of greatest importance were gas and coke. From the coke we obtain electric light carbons, and carbide of calcium used in the production of acetylene gas. Coal tar was the next production, and as the substances obtained from the distillation of this tar are practically innumerable, the principal products only were touched on.

We first obtain from coal tar a substance called benzol, which, combined with nitric acid, forms nitro-benzol, which is used extensively in the making of perfume. Next we procure carbolic acid, then creosote, a substance used for preserving railway ties, wharves, etc. Then follows naphthaline, used in the manufacture of camphor balls; in exceptionally cold temperatures this substance sometimes blocks up the gas pipes. We then obtain solid paraffins, principally in the form of waxes. The last product obtained through this distilling process of coal tar is pitch.

It was then shown how the articles and productions mentioned were applied to the manufacture of modern commodities of everyday use. The explosives used in modern warfare are composed largely of materials obtained from coal, such as carbolic acid, etc.; naphthaline goes into some of them, and is used in some of the cartridges of the present day. The speaker then exhibited samples of cordite and other explosives, and explained how smokeless powder differed from ordinary gunpowder. It was shown how natural articles of commerce were being imitated by productions from coal tar: such as oil of wintergreen, obtained from carbolic acid; musk, saccharine, which is 500 times sweeter than common sugar; and also artificial perfume resembling flower of lilac. In some diseases saccharine can be used where sugar could not. Gum-benzoic, naturally obtained from the sap of a tree grown in eastern countries, a substance which has been used from earliest times in making incense, and in all probability utilized in the preservation of mummies, is now artificially made in the form of benzoic acid. Mr. Williams had on exhibition a piece of gum-benzoic, which was over two hundred years old. A substance is also obtained from coal tar, which is used for much the same purposes as quinine in medicine.

At conclusion of the address a hearty vote of thanks was tendered Mr. Williams for his trouble in preparing such an interesting and exhaustive address on the subject. L. B. Mann, of Boston, a well known stationary engineer, addressed the meeting before it closed, and announced that he would be present at some meeting in the near future and address the members at some length. H. J. Wickens, of Toronto, made a few remarks, and a paper from him on electricity is looked for in the near future.

DOMINION ESTIMATES.

Railways and Canals.—The amount to be voted is $4,570,902, as against the current vote of $4,855,472. Of this the Intercolonial Railway is to receive $1,545,902, being $95,216 of a decrease. The Prince Edward Island Railway receives $713,500, as against $268,000 for the current year. Canals receive $2,311,500, as against $2,944,454 for the current year. The canal items are:

Soulanges canal, construction, $350,000; Sault Ste. Marie canal, construction, $40,000; Lachine canal, construction of lock, $500,000; Lachine canal, dredging between locks 2 and 3 and basin, $21,000; Lachine canal, building slope walls, $11,000; Lachine canal, build a quadrant pontoon gate, $20,000; Lachine canal, installation of electric light, $40,000; Lake St. Louis, forming channel, $14,000; Grenville canal enlargement, $5,000; Lake St. Francis, removing shoals, $5,000; Cornwall canal, enlargement, $60,000; Farran's Point canal, enlargement, $69,500; Galops canal, enlargement, $441,000; North Channel, forming $200,000; Galops Rapids, forming channel, $100,000; St. Lawrence River and Reaches, surveying, buoying, etc., $15,000; Trent canal, construction, $320,000; Welland canal, improvements to Port Colborne entrance, $100,000; total, $2,311,500.

In addition to the above which are chargeable to capital, there is $245,927 to be voted chargeable to income. Of this $9,000 is for Lake St. Francis; $17,000 for the Lachine canal, including $3,000 for new steel rollers for Wellington street bridge; $10,000 for St. Ours locks; $31,700 for the Carillon and Grenville canals.

Public Works, Capital.—The amount to be voted is $476,000, being an increase over the current vote of $24,000. Of this $433,000 is for the St. Lawrence ship canal, being the same as the current vote.

Public Works Income.—The amount to be voted is $1,095,423, as against $3,224,556 for the current year. The following appropriations are for Quebec:

Dominion public buildings, $12,000; Grosse Isle quarantine station, $10,000; Montreal public buildings, $5,000; Quebec Citadel, Governor-General's quarters, $2,000; Quebec custom house and examining warehouse, $2,000; Quebec immigration buildings on Louise embankment and breakwater, and Queen's wharf buildings, $5,000.

Harbors and Rivers.—Anse aux Gascons (Port Daniel East), breakwater, $1,300; Baie St. Paul (Cap aux Corbeaux), extension and repairs to wharf, $2,000; Beauport, wharf, $4,500; Berthier (en bas), repairs and open shed, $1,000; Carleton, extension of landing pier, $1,000; Grosse Isle, repairs to wharf, $1,500; general repairs and improvements to harbor, river and bridge works, $10,000; Lanoraie, repairs to wharf and construction of ice breaker, $2,500; Longueuil wharf, reconstruction and repairs, $2,500; Lower St. Lawrence, removal of rocks, $1,500; Magdalen Islands breakwater, $10,000; Matane, extension of training pier southwardly, $4,000; New Carlisle, repairs to wharf, $500; Newport breakwater, $7,000; Perce (North Cove), wharf, $10,000; Rimouski wharf repairs, $3,000; Riviere Cap de Chatte, pier, $000; Riviere a la Pipe, wharf on Lake St. John, near mouth of river, $1,000; Rive St. Maurice, channel between Grandes Piles and La Tuque, dredging, $6,300; St. Alexis, Baie des Ha! Ha! pier, $4,000; St. Alphonse (Bagotville), landing pier, repairs and shed, $500; Ste. Anne de Sorel, ice piers, $2,000; St. Fulgence, pier and improvements, $1,500; St. Jerome (Lake St. John), wharf, $2,500; St. Laurent, repairs to wharf, $700.

ARNOLD MAGNETIC CLUTCH.

In the design of the modern electric power plant it is frequently found desirable to arrange the generators in such a way that they may be readily connected or disconnected to the prime movers according to the exigencies of the service. This requirement of station design has been met by Br. Bion J. Arnold in the system known by his name. As this system requires the use of clutches, Mr. Arnold has worked out a magnetic clutch, a number of which have already been built.

These clutches are in reality friction clutches, yet the friction between the contact surfaces is not due to mechanical pressure, but to magnetic traction. The working parts of the clutches are composed of metal having a high permeability so arranged as to become magnetized upon the passage of direct current through the coils with which they are provided. The two parts of the clutch can be attracted together in this way with a pressure far in excess of that obtained in mechanical clutches, and it is only a question of making the clutches large enough, to enable them to transmit power in any desired amount. The energizing circuit is controlled by means of a switch placed at a convenient point, which is quite a decided advantage over the ordinary friction clutch. It thus becomes possible in throwing a generator in or out of service to control it entirely from the switchboard, where all the regulating devices and measuring instruments are within the reach of one attendant. These magnetic clutches also possess the advantages of neat appearance and compact design. Even in the larger sizes the amount of space occupied upon the shaft is not much more than twice the diameter of the shaft, and by using a flange forged solid on the end of the shaft, they can be made to occupy even less space when used as cut-off couplings. Owing to their having no projecting surface or parts to catch the air when in operation the windage resistance is negligible. The greatest advantage, however, of this form of clutch over others is the fact that it is self contained—the "action and reaction" being within the clutch itself, and consequently there is no resulting end thrust upon the shaft bearings and no additional friction load due to the operation of the clutch. The illustration, Fig 2, shows the largest magnetic clutch in the world. It is 100 inches in diameter, and is capable of transmitting 3,000 h.p. at 150 revolutions per minute. This clutch is one of three now in use connecting the engines and generators in the central station of the Imperial Electric Light, Heat & Power Company at St Louis, a view of the equipment of which is shown in Fig. 1. The experience with this plant demonstrates that this form of clutch is applicable to the large size units now being installed for power station purposes, whereas the ordinary friction clutch becomes especially unwieldy and unsightly after passing the 500-h.p. size.

The current is carried to the clutch coils through contact rings upon the side of the clutch, and carbon brushes held by insulated brush holders. The electrical connections are simple and easily accessible for inspection. The clutch requires no more current than would be used by four 16-c.p. incandescent lamps, and the loss in the clutch due to the continuous use of the electric current while the clutch is in operation amounts to only one-hundredth of 1 per cent. of the power transmitting capacity.

A number of these clutches have been made to connect large synchronous motors to their load in such a way that they can be quickly disconnected in case of accident, and they have also been built for use upon line shafting. They are also particularly applicable to use in connection with gas engines, as they would eliminate the flywheel problem of the gas engine in many cases, which of itself would be a distinct advantage. Indeed, there would seem to be no limit to their use wherever it is desired to transmit power from one shaft to another.

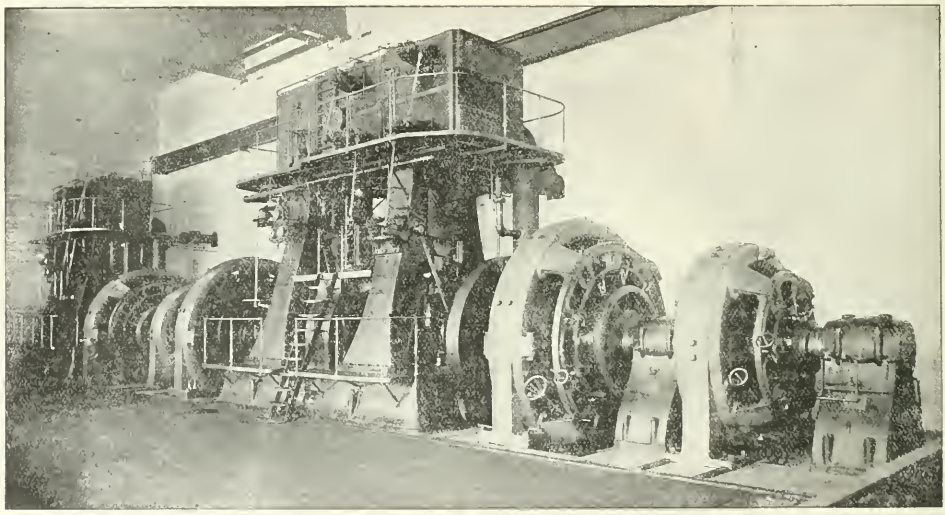


FIG. 1. THE IMPERIAL ELECTRIC LIGHT, HEAT AND POWER CO.'S PLANT, ST. LOUIS, U.S.

ELECTRIC TRAVELING CRANES

One of the subjects discussed at the Engineering Conference of the Institution of Civil Engineers in England last year was "Cranes and the Power to be Used with Them." The debate was opened by Walter Pitt, who spoke strongly in favor of electric power; indeed, he recommended it for all cranes, except those used singly, or with a great range of portability. Of course his views did not go unchallenged, seeing that he allowed but little future for the hydraulic crane, which is eminently adapted for certain classes of work. But he carried his audience with him entirely when he said that electric driving was the only one to use for overhead travelers. This is a matter which admits of no argument; the great requisite of an overhead crane is convenience in use and manipulation. There are others, but this is the chief, for a crane which can be used quickly and easily will very soon save its cost in a works. There are no travelers which fulfil this condition like those driven by electricity, particularly when the designer has had the courage to avail himself to the full of the agent which he employs. The early cranes had one motor, and the power was distributed from this to the hoisting barrel, and to the longitudinal and traversing gears by belts or other mechanisms. The arrangement was an improvement on the familiar square shaft, but still it was very faulty. It showed that the designer feared the electric motor

would give trouble, and, therefore, he thought it wise to restrict himself to a single one. No doubt he was right; motors have been immensely improved of late years, and in no respect more than by the use of the carbon brush. Without that it would have been a difficult matter to have brought the electric tramcar to the point of commercial success which it now enjoys, and other forms of motive power transmission would have failed, in a greater or less degree, to attain their present established position.

The success of the electric tramway upsets every possible objection which can be raised against the reliability of the electric motor for other purposes. On a car it runs among slush and mud, is stopped and started every two or three minutes, and has often to get into motion under loads many times the normal. It may safely be said that if an electric motor succeeds in such work—and it certainly does succeed—it may be employed with the fullest confidence in every position in an engineer's shop, for there it meets with skilled care, and the greatest demands that can be made upon it are uniformly easier than those found in a tramway. It may be a moot point how far the subdivision of electric power should be carried in the driving of tools, but its applicability and economy of power when used in traveling cranes has passed beyond the stage of discussion. The question of economy in the driving of a crane is, however, of little moment. What does matter is that no time shall be lost at the tools Lathes, planing machines, and other appliances now represent such an immense capital outlay that it is most imperative that they shall work every available minute, and this can only be done if the work can be lifted in and out with expedition and with certainty. For this work there is nothing on the market equal to the electric crane.

The most advanced practice in overhead travelers is to use a separate motor for each motion. It is not many years that Messrs. Adamson have been making cranes, their original business being that of boilermakers, and it will be interesting if we trace their connection with the new industry, as their experience reflects in a general way the history of the electric crane in this country, says Engineering, London, Eng., in a recent issue. In the early nineties the firm were in want of two additional overhead cranes, and after considerable enquiries they determined that they should be electrically driven, and that they would build them themselves, because at that time the established makers did not recommend this application of electric power. The makers of motors also cast very considerable doubt on the advisability of using reversing motors, while at the same time the cost of the motors was very high. In 1893 one of the firm went to the United States, and soon found that there did not exist the same hesitancy about using reversing motors on the other side of the Atlantic as here, and he returned with the conviction that they might proceed with confidence. On November 5, 1894, they set to work their first three motor crane, and during the next two years they constructed cranes for their own shop, proceeding tentatively and experimenting at their own cost rather than at that of their customers. In that period they built five or six cranes, not only as regards the ironwork, but also the motors and the electrical equipment. In 1897 they began working for the public, and have since turned out cranes of various sizes.

FIG. 2 ARNOLD MAGNETIC CLUTCH.

The latest crane has four motors. Their purposes are respectively to drive (1) the main barrel, (2) the light barrel, (3) the longitudinal motion, and (4) the traverse motion, and all are supplied with current at 220 volts. The main lifting speed is 4 feet per minute, the corresponding motor running at 400 revolutions per minute, and the barrel being 2 ft. 6 in. in diameter, there being three intermediate shafts between the motor and the barrel. All these spur gears are machine cut out of the solid, except the last two, which are of the double helical type, all being of steel. The first motion wheel has a bronze rim bolted on it. The use of keys is avoided wherever possible, the pinions are forged solid on their shafts, and the wheels are keyed on prolonged bosses formed on the pinions to receive them. The load is carried by a steel wire rope 5 inches in circumference, passing in two bights round two sheaves on the hook block. The two ends of the rope are fixed to the drum, and the centre bight is led round an equalizing pulley, thus

giving a true vertical lift. The light lift is intended to deal with loads up to five tons, and has a barrel 1 ft. 4 in. in diameter, around which is wound from each end, a steel rope 2¼ inches in circumference. The speed of lifting is 15 feet per minute, and the revolutions of the motor 320 per minute. The speed is reduced at two steps by one worm reduction and a pair of spur-wheels. The worm has four threads, and gears into a wheel with machine-cut teeth on a bronze rim. The worm runs in an oil bath, and its thrust is taken up in a thrust bearing of the marine type. Both lifting drums are controlled by electric brakes. These are fixed to the motor shafts, and work automatically without care on the part of the attendant. The brake wheel is pressed on by shoes applied by springs and released by an electromagnet, which is energized when the current is directed to the corresponding motor. Thus, should the current fail from any accidental cause, the brake goes on immediately, and holds the load safely. On the other hand, immediately the attendant sets the crane to lift or lower, the brake is taken off. Should the load, in falling, drive the motor too rapidly, the back electromotive force would reduce the current, and the brake would go on of itself.

The longitudinal motion of the crane is effected by the motor fixed on the end of the main girders, the speed of the motor, 300 revolutions per minute, being reduced at two stages to give a traveling speed of 80 ft. per minute. The traverse motion is derived from the motor. This runs at 500 revolutions, and gives a speed of 40 ft. per minute through two reductions. The power absorbed by the four motors is as follows when the crane is fully loaded: Main hoist, 25 brake h.p.; auxiliary hoist, 12 brake h.p.; traversing, 7 brake h.p., and traveling longitudinally, 5 brake h.p. Leaving for the moment the electrical equipment, we will turn to the dimensions and construction of the crane itself. The height of lift is 22 feet, the span is 27 ft. 4 in., and the distance apart of the girders, centre to centre, 7 ft. 6½ in.

THE ONTARIO ASSOCIATION OF LAND SURVEYORS.

The convention of the Ontario Land Surveyors was held on Feb. 28th and March 1st in the Parliament Buildings, Toronto. The attendance was large, and the interest displayed most gratifying throughout, especially in the proposal to explore New Ontario. The election of officers resulted as follows: President, Geo. Ross, Welland; vice-president, James Dickson, Fenelon Falls; secretary-treasurer, Major Villiers Sankey, Toronto; Auditors, Capt. K. Gamble, H. J. Browne. The following were nominated as councillors, election to take place by letter ballot on April 3: Capt. W. F. Van Buskirk, Stratford; Messrs. A. J. Van Nostrand, Toronto; E. T. Wilkie, Carleton Place; W. R. Aylesworth, Belleville; J. W. Tyrrell, Hamilton; H. H. Gibson, Willowdale; A. S. Code, Alvinston; John McAree, Rat Portage.

The next issue of The Canadian Engineer will contain a more detailed report of the meeting.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports from Great Britain, of interest to the metal trades, in January, 1899 and 1900:

	Jan. 1899.	Jan. 1900
Hardware	1,538	2,068
Pig iron	361	2,000
Bar, etc	445	1,100
Railroad		321
Hoops, sheets, etc	125	2,005
Galvanized sheets	488	5,730
Tin plates	5,685	14,738
Cast, wrought, etc., iron	997	3,201
Old (for remanufacture)		2,485
Steel	3,770	22,449
Lead	889	1,052
Tin, unwrought	2,515	3,377
Alkali	1,543	2,691
Cement	213	272

THE PROPERTIES OF NICKEL-STEEL.

Brief notices have appeared from time to time in The Comptes Rendus of the French Academy upon M. Guillaume's important researches into the physical properties of the various alloys of nickel and steel, but the complete details of these investigations have not been made public until recently. A paper by M. Guillaume in The Bulletin de la Societe d'Encouragement now describes the apparatus and methods used by him, and also gives the results of his researches more completely than they have been given heretofore. While it is impossible, in limited space available, says The Engineering Magazine in reviewing the article, to examine the work of M. Guillaume at length, the peculiar properties which he has discovered possess sufficient importance to demand a brief indication, and may render the application of the alloys important for engineering purposes in different lines from those previously considered. The principal object in view, in making these researches, was the discovery of the best alloy for metrological purposes, and the investigations covered the density, elasticity, magnetic properties, and behavior under the action of heat. They were not intended to cover the entire magnetic properties of the various alloys, but only to use these as guides to the selection of suitable proportions for further investigation. These tests showed that alloys containing from 0 to 25 per cent. of nickel are irreversible—that is, they possess two different sets of magnetic properties, according to the direction of the preceding temperature-changes, whether ascending or descending. For alloys containing 25 to 50 per cent. of nickel, on the contrary, the magnetic properties are reversible, depending at each temperature upon the temperature only, regardless of the preceding condition.

A similar condition of reversibility, or irreversibility, appeared in connection with changes of volume, the irreversible alloys showing, within certain limits, absolutely different changes when subjected to ascending and descending temperatures. The reversible alloys expanded and contracted in the same manner, whether cooled or warmed, but seemed to follow laws altogether different from those governing other metals or alloys. The peculiar behavior of the irreversible alloys can be shown only by a diagram, but the expansion and contraction of the reversible alloys is tabulated in a very interesting manner. The formula for the coefficient of expansion is given in the shape of a constant plus a function of the temperature, but neither the constant or the coefficient remains the same for different alloys. As the proportion of nickel is increased, the coefficient of expansion diminishes until the minimum is reached for the alloy containing 35.6 per cent. of nickel, after which it again increases. At this minimum proportion the expansibility is only one-tenth that of platinum, and less than one-twentieth that of brass. The great value of this alloy for standard measures of length will be seen at once, especially as it possesses other desirable qualities. The alloy is particularly homogeneous, takes a brilliant polish, remarkably free from flaws, and has a density of about eight and a modulus of elasticity of about 20,000,000 pounds per square inch.

In order to attain the best results, the bar of this alloy is subjected to a prolonged elevation of temperature, lasting for several days, after which the molecules appear to have arranged themselves in the most stable position, so that the subsequent changes of length for differences of temperature are reduced to a minimum. The influence of this reheating also renders the small, but ordinarily somewhat variable, expansion coefficient practically constant. If it is desired to secure a variation of less than 0.001 millimeter in a length of one meter, the bar should be maintained at a temperature of boiling water for 80 to 100 hours. A still greater degree of precision may be obtained by giving the bar a series of prolonged heatings for several hundred hours at successively diminishing temperatures; in this way bars for the measurement of geodetic base lines may be obtained with the temperature error practically eliminated.

A variation of 1 mikron per meter in the length of a pendulum corresponds to less than 0.05 second per day; in fact, a clock with a pendulum rod of this alloy has shown a rate of less than 0.02 second per day for a period of six months.

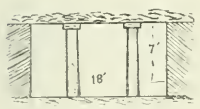
Although the researches of M. Guillaume are not yet completed, the facts which he has made public are of much value, and his full account of his work will be found both interesting and practical.

NOTES ON THE DEPOSITION AND DEVELOPMENT OF THE GLACE BAY COAL SEAMS.*

BY S. F. KIRKPATRICK, B.SC.

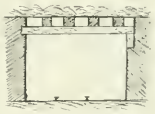
At the commencement of carboniferous times the north eastern portion of Cape Breton was overlain by a deep clear sea, favorable to the growth of coral and the deposition of limestone and gypsum. At the close of the lower carboniferous age the sea became shallower and towards the end of the formation of the millstone grit we find the rivers depositing clay, coarse sand and gravel. The succeeding age was one of extensive vegetable growth; and the rising sea-bottom became in part a swamp where the successful growth of forests deposited great depths of bituminous matter. The vegetable matter from the land probably accumulated at certain times in the shallow sea in sufficient quantities to form coal seams. When the land slowly sank fine sediment was carried down by the rivers forming shales and sandstones. These are impregnated with fossil remains of plant life and in some cases fossil animal remains.

Later on the former conditions may have been reproduced by a further upheaval or shallowing of the sea. So with the action of time and pressure we have a formation composed of sandstones, shales and marls containing beds of coal. During the ages that have passed since the carboniferous times, part of the coal measures have been worn away, a large area sunk beneath the Gulf of St. Lawrence and the continuity of the beds destroyed by faulting. The strata has also been thrown into undulations, so the dip and strike of the coal seams vary very considerably at different parts of the Cape Breton coal fields. There is reason to suppose that this coal field is only the end of an immense coal area, now underlying the Gulf of St. Lawrence, extending to Newfoundland, and underlying the Magdalene Islands.

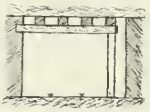


ORDINARY ROOM TIMBERING.

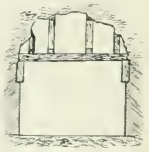
IN LEVEL WHEN NO PROPS CAN BE USED.



ROOF AND ONE SIDE BAD.



ROOF AND ONE SIDE BAD.



LEVEL OR DEEP AFTER FALL OF ROOF.

The Glace Bay coal beds, worked by the Dominion Coal Co., form an eliptical basin, the longitudinal axis running nearly due east and west. The greater part of this basin is under the sea; the western end only being available for mining operations. This portion is bounded on the north and east by the sea coast, and on the west and south by the anticlinals of Lingan and Cow Bay. The Lingan anticlinal is also a line of faulting, and it is as yet undetermined if there is a fault along the Cow Bay anticlinal. In this basin there are four seams of coal of considerable thickness that may be worked profitably. They are as follows:

	Approximate thickness.
Hub, coal	8½ feet.
Sandstones, shales and limestones	320 feet.
Harbor, coal	6 feet.
Sandstones, shales and limestones	400 feet.
Phelan, coal	7 feet.
Sandstones, shales and limestones	165 feet.
Emery, coal	5 feet.

The inclination of the seams vary, but it is usually under six degrees. Of the six collieries hoisting in 1908, four were working the Phelan seam, viz., Caledonia, Dominion No. 1, Old Bridgeport and Reserve.

The question of where to locate the opening of a mine and what form of opening is best generally depends on the property. A thorough knowledge of the extent of the seam, its depth, inclination and thickness are required. These facts may be obtained by examining the outcrop, and boring through the overlying strata, and further verified by slopes and drifts. Usually in mountainous country, where the strata is at a considerable inclination, it is practical to work the coal by tunnels. But in this particular case the choice lies between shafts and slopes. The latter are adapted to seams at a considerable inclination, where the outcrop is on the property, and a cheap development required. Shafts are necessary when the seam is only slightly inclined or when two or more beds are to be worked from the same bankhead. They are also best adapted to mining on a large scale, when quick returns are not so important as the ultimate cost of raising coal per ton. The question of where to sink the shaft depends, to a great extent, on the amount of capital available for development. If the shaft is sunk well to the rise the cost of hauling the coal to the pit bottom is greater, but the cost of sinking less and an early output is available. On the other hand a deep shaft would allow of a less costly system of haulage, but would take more time and money. Up to the present the greater number of the Glace Bay coal pits have compromised by sinking a shaft from 150 feet to 180 feet deep, so at first a large part of the coal could be brought to the pit bottom by gravity. This plan will no longer be followed as the Dominion Coal Co. is engaged in sinking a deep shaft to work more than one seam. Usually the shaft has three compartments, two for hoisting the mine cars and one for a man lift. The dimensions will depend to a great extent on the shape of the mine cars; which is governed by the thickness of the seam and the character of the roof. The former regulates the height of the car and the latter the breadth, because a brittle roof will allow of wider workings and consequently wider cars.

The question of the method to be employed in working the coal now arises. The chief systems are the long-wall and the pillar and stall. By the former all the coal is taken out by cutting along the wall or face of the coal, either commencing from the shaft and working out towards the boundary or by running tunnels or haulage ways to the boundary and working towards the shaft. This would be adapted to shallow seams, especially where there is a sufficient amount of splint slate, etc., in the coal to make supports, called gob-walls, for the roof. Usually, however, the roof is allowed to fall in, then if the surface property is of value there must be a sufficient depth of overlying strata to prevent the cave-in coming to the surface. By the pillar and stall method only part of the coal is removed by cutting out tunnels or rooms and leaving sufficiently large pillars of solid coal to support the overlying strata.

At the Glace Bay coal fields almost all the coal is mined in this way, for on account of the thickness of the seam and the small amount of rubbish in the coal they would have to allow the roof to cave in, when much damage would be done to the surface property. Of course it would be possible to support the roof by a system of blocks and heavy timbers, but such a method would be too costly. After sinking to the seam, levels are run out in the direction of the strike of the coal and the deeps, two or more run parallel or radiating from the pit bottom. Both deeps and levels are worked in pairs, that is two parallel tunnels usually 12 feet wide with a 12-foot wall between them. Every 66 feet they are connected by a 9-foot cross-cut, to allow the air to circulate and so ventilate the working face. A large part of the coal around the shaft is not mined but allowed to remain to prevent the settling of the ground under the bankhead and the surface buildings that are generally around the shaft. The rooms or stalls are cut off from the levels, and are worked towards the outcrop parallel to the plane of the coal.

They are about 18 feet wide with a 12-foot wall between them, and are connected every 66 feet by a 9-foot cross-cut. After working some distance down the deeps, levels are turned off as before, and rooms are commenced on this level to cut up

*From a paper read before the Applied Science Society of McGill University, Montreal.

to the higher level. In this way the entire coal area is honeycombed from the shaft out towards the boundary. When the whole area has been worked in this way, part of the remaining 40 per cent. of coal may be recovered by robbing the pillars, that is removing the whole or part of the remaining coal, working from the boundary, allowing the surface to fall in if necessary.

The timbering of a pit worked on this principle is not extensive. The overlying strata is supported by the coal pillars; but the roof of the rooms must be further supported by one or two rows of timber, say 6 inches in diameter, and placed from 4 to 8 feet apart. Occasionally the roof of the haulage ways is supported by cross timbers set in the walls or resting on one or two props. The timbers used in the main airways are usually the best 8 inch props, for there the timber is more liable to rot, due to the large quantity of air that flows past having a very deteriorating effect on them. If the coal pillars at any part of the mine begin to crush on account of the weight of the overlying strata, then very heavy timbering must be resorted to, and a larger percentage of the coal left as pillars. On the traveling roads and haulage ways the old props are frequently replaced by new ones, for the average length of a prop is only from two to four years, and on main airways often not a year. Before the work of development has advanced very far it is necessary to put in some system of haulage. The mine cars here have a capacity of from 1½ to 2 tons, and run on a narrow gauge tramway. They are filled at the working face, and are drawn by horses to the main deeps and levels. The coal mined above the pit-bottom can be let down by gravity, the full cars going down pulling up the empties. When this is not possible some form of rope haulage is employed.

The two chief methods in use in Cape Breton are the tail-rope and endless cable systems. In the former the cars are drawn in trips, that is from eight to fifteen cars hitched together. In this system there is only one track and two ropes, one for hauling the loaded cars to the pit bottom, and the other of double the length of the road passing around a wheel at the end of the level or deep to pull the empties back to the working face. The engines are usually situated underground, near the pit bottom, and turn two drums of equal diameter, so that the one will be taking in the main rope, while the other is letting out the tail-rope, and vice versa. The main rope is a much heavier cable than the tail-rope, and will be as long as the road, the tail-rope will be twice this length. In the second system there is a double track and an endless cable kept moving at the rate of about two miles per hour along one track and back the other. The cars are attached to the cable by friction grips. The full cars are drawn to the pit bottom on one track and the empties taken back on the other. The advantages of this system are: 1. Less wear on cable and on roadbed due to slower speed. 2. The tubs arrive at the pit-bottom one at a time, and the strain on the cable is more equalized on account of the cars being fairly equally spaced. 3. The cable is only double the length of the road. 4. Only one engineer is required to manage three or four endless cables.

The disadvantages are: 1. A double track is required, therefore, the deeps and levels must be wider than in the single track system, and the initial cost of roadbeds and tracks more. 2. The initial cost of the power plant will be greater. 3. Cost of maintenance of roadbed more. 4. The cable will be damaged by the grips, and accidents are often caused in the deeps by the grips slipping. When the mine car is hauled to the pit-bottom it is run on to the hoist, where it is held by an automatic clutch; it is lifted to the bankhead, and dumped, and then lowered at the same time, as the next full car is being hoisted in the adjoining compartment. The lifts are run thus in balance, the weights of the cars and cages counter balancing. The mine is usually kept dry by draining the deeps with compressed air pumps discharging into a sump or reservoir at the pit bottom, and from there it is forced to the surface by a steam pump.

In all mines of this class some form of artificial ventilation must be employed. There are at least two openings to the mine, and it is so arranged by leaving walls of coal and walling up passages, that the air entering one shaft is divided so that some of it will pass through each part of the mine before finding its way up the second shaft. During the earlier stages of development, and in certain cases of deep shafts it may be economical to force this current of air by heating the air in the upcast shaft by a fire at the foot, and so rarifying the air that it tends to rise and draw air through the mine from the other shaft. More often, however, some form of fan is used to exhaust or compress the air in one of the shafts.

GENERAL ENGINEERING COMPANY VS. THE DOMINION COTTON MILLS COMPANY AND AMERICAN STOKER COMPANY.

In a reference in our last issue to the litigation now going on between the General Engineering Company, of Toronto, and the American Stoker Company some errors occurred which we very much regret. In referring to the progress of the case it was stated that, "it was carried by the defendant companies from one court to another until it reached the Exchequer Court." The fact was that the action brought by the General Engineering Company was begun in the Exchequer Court, and all the proceedings have been in that Court. By a slip of the pen it was stated that an "injunction" had been granted instead of a "judgment" given. The substance of this judgment was given in our issue of October last, but it appears that formal judgment was not taken out, an application for a new trial having been made in the meantime by the defendants. This application first came up at Osgoode Hall on the 5th of July, and was enlarged at plaintiff's request until the 19th of September. Between these two dates the American Stoker Company applied for a writ of *scire facias* asking for the repeal of one of the Jones Stoker patents on the ground that it had expired. Judgment was given in this action in favor of the General Engineering Company on the ground that a writ of *scire facias* was not the proper remedy. The application for a new trial was then renewed by the defendants, and an order given by the Court to the following effect: That a new trial may be had on condition that the defendants pay plaintiff's costs to date, that the previous judgment be set aside, that at the new trial new evidence should be limited to the issues as to whether letters patent No. 40,700 in plaintiff's statement of claim had become void by expiry at the time of the infringements alleged, and prior to the institution of this action. It will be seen that there is no judgment now standing in the case, no damages were ever awarded, and no injunction was ever issued against the American Stoker Company. The Exchequer Court has as yet expressed no opinion, as to whether or not the patent in question is still in force, or has become void by expiry. The public are not restrained by injunction from putting in the stokers of the American Stoker Company, and the American Stoker Company is not prohibited from doing business in Canada.

NEW LAND SURVEYORS.

Commissions as Dominion Land Surveyors have been granted to C. W. MacPherson, O.L.S., Barrie, Ont.; R. Rinfret, B.A.Sc. (McGill), P.L.S., Montreal, Que.; F. J. Robinson, S.P.S., Toronto, O.L.S., Barrie, Ont.; J. N. Wallace, B.A. and B.C.E. (Dublin), O.L.S., Hamilton, Ont. The following candidates were admitted as pupils: R. H. Cautley, Ipswich, England; F. W. O. Werry, B.A. (Toronto), Ottawa, Ont.

At the recent meeting of the Board of Examiners for Ontario Land Surveyors the following candidates were admitted to practice: Wm. Walter Stull, Sudbury, Ont.; William Howard Fairchild, Simcoe, Ont.; John Henry Shaw, Pembroke, Ont., and Melville Bell Weekes, Brantford, Ont. Leonard Oswald Clarke, of London, passed the preliminary examination, and received a certificate admitting him to apprenticeship.

IT BENEFITS READERS.

Editor CANADIAN ENGINEER :

I am very much pleased with your paper, and although I have only received two numbers as yet I have derived a great deal of benefit from them. Yours sincerely,

Providence, R.I., Feb. 13th, 1900. G. V. HAMILTON.

Waring, Chapman & Farquhar, New York, have prepared plans for a system of sewerage for Ashly, a residential town now building by the Dominion Iron and Steel Co., near Sydney, C.B.

THE USE OF BOILER COMPOUNDS.*

BY ALBERT A. CARY.

To the majority of steam users, anything that is put into a boiler to lessen troubles due to the formation of scale, is a "boiler compound;" and the fact that these various so-called compounds act differently in their endeavor to accomplish their purpose is not as generally understood as it should be by those who persist in their use. Such nostrums may be divided into three classes:

First—Those attacking the scale-producing material chemically, and acting as re-agents, combine with the matter precipitated from the feed water, forming a third substance different from either the original precipitated solids or the "re-agent," the theory being that the new substance will not form into a hard, resisting scale, and therefore can be more easily removed by blowing off or by the cleaning tools used after the boiler is "opened up." Second—Those acting mechanically upon the precipitated crystals of scale-making matter soon after they are formed. Such "compounds" are of a glutinous, starchy or oily nature, and become attached to the surface of the newly formed crystals (precipitated from the water) surrounding them, as the skin does an orange; and when these crystals fall together they are thus robbed of their cement-like action, which frequently occurs when they are allowed to come in immediate contact. Third—Those acting both mechanically (as just described) and also as a solvent, the latter action partially dissolving scale already formed, and by this "rotting" effect (as it is often called), preparing the scale for easy removal.

The "compounds" under the first division (which act chemically upon the scale-forming matter) also frequently accomplish this same rotting effect upon scale formed previous to their use. Still other divisions or subdivisions might possibly be made, but the above will suffice for a good general idea of the subject. Taking up our first division of this subject, we find that the principal ingredients used in such "compounds" are soda ash (or carbonate of soda) and tannin matters, while we sometimes find caustic soda, sal soda, acetic acid and numerous other active agents which are generally less efficient in their action on the scale-forming matter and more harmful to the boiler and its fittings. In order to disguise these very cheap chemicals and help the "compound" vendor get prices for his powder or liquid, whichever, it may be, there are often added other substances which generally render the active agents less efficient, and they frequently fall unchanged to the bottom of the boiler with the scale, thus increasing the deposit and aggravating the trouble. Such added substances include clay, chalk, sand, etc., and sometimes merely coloring matter is used to disguise the original chemicals, such as tobacco juice, iron scraps, lamp black, spent tan, etc.

The principal scale-making impurities precipitated in boilers are carbonate of lime ($CaCO_3$), carbonate of magnesium ($MgCO_3$), sulphate of lime ($CaSO_4$) and sulphate of magnesium ($MgSO_4$), and, although there are generally other precipitates, notice of these alone will be sufficient for the present consideration. The chemical action taking place when some of the above named active agents are used may be traced as follows: Soda ash is a dry impure carbonate of soda, from which the pure alkali is afterwards made. The carbonate of soda (Na_2CO_3) is used to act upon the sulphate of lime and magnesia, as shown in the following chemical formulae:

	Sulphate of Lime	and	Carbonate of Soda
(a)	$CaSO_4$	+	Na_2CO_3=
		form	
	Carbonate of Lime	and	Sulphate of Soda
	$CaCO_3$	+	Na_2SO_4
	Sulphate of Magnesium	and	Carbonate of Soda
(b)	$MgSO_4$	+	Na_2CO_3=
		form	
	Carbonate of Magnesia	and	Sulphate of Soda
	$MgCO_3$	+	Na_2SO_4

Leaving this treatment for a moment, it would be well to note that both the carbonate of lime and carbonate of magnesia are held in solution through the presence of carbonic acid gas dissolved in the water, which unites with them and changes the mono-carbonates into bi-carbonates (which are only known to exist in solution), as shown thus:

Carbonate of Lime
$CaCO_3$=
composed of

Oxide of Lime	and	Carbonic Acid
CaO	+	CO_2

Carbonate of Lime	and	Carbonic Acid	and	Water
$CaOCO_2$	+	CO_2	+	H_2O=

form

Bi-Carbonate of Lime
$CaO(CO_2)_2H_2O$

Bi-Carbonate of Lime		Generally Expressed
$CaO(CO_2)_2H_2O$	=	$CaH_2(CO_3)_2$

In a similar manner the bi-carbonate of magnesium is formed from the mono-carbonate thus:

Carbonate of Magnesium
$MgCO_3$=
composed of

Oxide of Magnesium	and	Carbonic Acid
MgO	+	CO_2

Carbonate of Magnesium	and	Carbonic Acid	and	Water
$MgOCO_2$	+	CO_2	+	H_2O=

form

Bi-Carbonate of Magnesium
$MgO(CO_2)_2H_2O$

Bi-Carbonate of Magnesium		Generally Expressed
$MgO(CO_2)_2H_2$	=	$MgH_2(CO_3)_2$

The mono-carbonates (or single carbonates) of lime and magnesia are but slightly soluble in water, whereas the bi-carbonates, or double carbonates) are very soluble in cold water, and this fact will account for the presence of the large quantities of lime and magnesia in boiler waters as carbonates.

When waters containing the bi-carbonates are heated, the rise in temperature drives off the extra carbonic acid gas and leaves behind the practically insoluble mono-carbonates, which are precipitated.

When a temperature of 180 degrees Fahr. is reached, a considerable percentage of the bi-carbonates is precipitated (as insoluble mono-carbonates), and at 290 degrees Fahr. (a temperature corresponding to 43 pounds gauge pressure) the precipitation is nearly completed, after a thorough boiling.

Scale formed from the mono-carbonate of lime is seldom very troublesome, if not allowed to accumulate in too large a quantity, nor allowed to remain in the boiler for a long time; while the precipitated mono-carbonate of magnesia gives slightly more trouble, due to the fact that it seldom is found in scale as a mono-carbonate. All the contained carbonic acid (CO_2) is generally lost from the bi-carbonate of magnesia ($MgO(CO_2)_2H_2O$) by the time it forms a crust, leaving behind the hydrate of magnesia ($MgO + H_2O = MgO_2H_2$), which acts as a cement and binds closely together (though not very strongly) whatever precipitated matter it may come in contact with. This hydrate of magnesia is very fine and light when precipitated and requires a comparatively long time to settle.

(To be continued).

THE RED CROSS FUND

BIGGAR, SAMUEL & CO.,
PUBLISHERS CANADIAN ENGINEER.

Gentlemen,—I desire gratefully to acknowledge your handsome donation of $36, the profits on the sale of the 5th edition of your pamphlet on the Boer war. The donation is especially opportune at this time when so many of our brave fellows—Colonial and Imperial—are being wounded in their heroic efforts to uphold the cause of equal rights and true British liberty. Very sincerely yours,

J. GEORGE HODGINS,
Hon. Treas. of the British Red Cross Society, Canadian Branch.
Toronto, February 28th, 1900.

Collingwood, Ont., will vote on May 30th on a grant of $115,000 bonus to Chas. Cramp, Philadelphia, the well-known shipbuilder, to establish a smelter, capacity of 200 tons a day, in that town. There is to be an open hearth steel plant of three Wellman furnaces, and a rolling mill capable of making armor plates.

Industrial Notes.

Brantford, Ont., wants a steam road roller.

The Kingsville, Ont., glass factory will use natural gas as fuel

A large tobacco factory is being built at Kingsville by local capital.

The town of Smith's Falls paid A. Foster $35.000 for the waterworks system.

The Massey-Harris Co., Ltd., Toronto, has given $5.000 to the Patriotic Fund.

Wages of machinists employed by the C.P.R. in Toronto and Toronto Junction have been advanced.

The Reids are going to build a modern hotel, with some 200 rooms, in Fort William, St. John's, Nfld.

West & Peachey, Simcoe, Ont., have received orders recently for two of their Alligator warping tugs.

One hundred and fifty 60,000 lb. freight cars are building in Nova Scotia for the Dominion Iron & Steel Co.

The Carborundum Co., Niagara Falls, N.Y., has issued an interesting booklet, "Many Expressions, One Opinion."

The Collingwood Meat Co., Ltd., will put in at once 150 h.p. engine, and a refrigerating plant of 150 tons capacity.

Members of the board of trade, Arnprior, Ont., have subscribed $9.000 towards building a flour mill in that town.

A. J. Moxham, manager of the Dominion Iron and Steel Co., Sydney, C.B., will build a $30,000 residence at Colby, C.B.

The Walkerville, Ont., match factory is being equipped with engines and boilers by E. Leonard & Sons, London, Ont.

A well-known firm in Great Britain desires to be placed in communication with users of all kind of iron and steel tubing in Canada.

The Hamilton, Ont., Wheel and Foundry Company has advanced the wages of its moulders, the raise taking effect on February 16th.

The Keewatin Lumber & Mnfg. Co. has been closed down for a short time to build a new flume which will give a much improved power.

The Connors syndicate has awarded the contract for the elevator at Montreal to Barrett & Record, Chicago. It will cost about $1,500,000.

Essex county, Ont., has appropriated $16,000 to build a poor house. The site has not yet been chosen. Leamington offers free fuel and light.

The Manitoba Government engineer has recommended the construction of a steel bridge over the Little Saskatchewan River at Rapid City, Man.

There is reported to be a great scarcity of labor in Sault Ste. Marie, Ont., where F. H. Clergue is promoting a number of very extensive works.

The Marshall, Wells Hardware Co., Ltd., of Duluth, is incorporating a branch house, under the same name, to do business in Winnipeg, Man.

Application has been made for a charter by the Stony Plain Milling Co., Edmonton, N.W.T., to run a sawmill at Stony Plain; capital, $4,000.

The St. Charles Condensing Co., St. Charles, Ill., has established a branch in Ingersoll, Ont. The engines are Corliss, built by J. Inglis Co., Ltd., Toronto.

An association of those interested in cold storage and refrigeration is being formed in London, Eng. The secretary is S. M. Leonard, 19 Ludgate Hill, London, E.C.

The Smart Eby Machine Co., 195 Barton street east, Hamilton, is placing on the market a shaking and dumping grate bar, concerning which some strong claims are made in the advertisement in this issue.

A new type of wood pulp grinder, manufactured by McOuat & McRae, Lachute Que., is noticed in another column. This will be described in next issue; meantime those interested will get particulars on writing to the firm.

Ottawa, Ont., will spend $80,000 additional to the huge appropriation already made in its main drainage scheme. Part of the drain will be built outside the city limits.

The Fensom Elevator Works, Toronto, have the contract for the elevators for the South African Mutual Life Insurance Co.'s building at Port Elizabeth, Cape Colony.

S. B. Best has succeeded as manager of the Canadian Typograph Co., F. S. Evans, who has recently become manager of the National Cycle and Automobile Co., Toronto.

The Nickel Steel Co. is applying for powers similar to those conferred by the Railway Act upon railways, enabling it to expropriate lands, build railway lines, sidings, etc.

The Goldie & McCulloch Co., Ltd., Galt, Ont., has begun the year well. There have been sold 29 engines in the first 43 days of this year. All other departments are also very busy.

The contract for the new public buildings at New Westminster, B.C., has been awarded to Bourque & Des Rivieres, Ottawa, Ont. The amount is in the neighborhood of $60.000.

St. Louis, Que., will grant a bonus to the Phoenix Bridge and Iron Works if they build a $25,000 building, put in a $50.000 plant, employ at least 150 men, and pay $60.000 a year in wages.

There were during February 1,063 boarders at the Dominion Iron and Steel Company's dining-room, Sydney, C.B. The company have appointed nine new policemen to watch the works.

A sewage disposal plant is desired for the west end of Hamilton, Ont. E. G. Barrow, C.E., has recommended filtration as cheapest in operation. The plants already installed are chemical precipitation.

The contract for the locks, etc., at St. Andrew's Rapids, near Winnipeg, Man., has been let to T. Kelley, contractor, Winnipeg. The work will cost between one-half and one million dollars before it is completed.

C. H. Rust, city engineer, Toronto, has drawn plans for the proposed Yonge street overhead bridge. The width is 32 feet, having a 20-foot roadway and two 6-foot sidewalks. There is a double line of street railway tracks.

The Canadian Steel Co. is applying for incorporation to do a general mining, smelting, rolling mill and general construction business. Operations are to be carried on in Welland, Ont., and Hull, Que., and elsewhere.

W. M. Watson, 92 Dundas street, Toronto, whose articles on sanitary matters have interested our readers for some years past, is going to England at the end of this month to examine into the latest ideas in sewage disposal, etc.

The Canadian Canoe Co., Peterboro, Ont., has been running overtime since January 1st., and has already booked a larger number of orders than during any previous season. The No. 16 canoe is proving very popular, as in past years.

At the Montreal Rolling Mills Co.'s annual meeting the following were elected officers: A. Allan, president; E. S. Clouston, vice-president; H. M. Allan, H. Archibald, Hon. G. A. Drummond, J. S. McLennan, and W. McMaster, directors.

The chief of the fire brigade in Montreal has written the city council demanding that the high buildings in that city be compelled to put in stand pipes. This is now not the case, and such buildings are in some cases entirely beyond the reach of the fire fighting apparatus.

The R. Woodman Mnfg. and Supply Co., Boston, Mass., is famous as makers of light railroad and mill supplies. The advertisement of patent speed indicators on another page will be read with interest by all engineers and machinists. A more detailed description of these specialties will appear in our April issue.

The Austin Separator Co., Detroit, Michigan, manufacturers of the Austin Steam and Oil Separators, have just shipped an order of seven 7-inch new pattern, Fig. E., iron, horizontal receiver machines for use in the immense new power plant of the London & Bristol Tramway Co., London, Eng., in connection with Allis engines. As this is one of the most important and complete power plants installed during the past year in Great Britain, the selection of these goods is a distinct honor to American industry.

H. B. Cann, R. Caie, S. A. Crowell, A. Cann, C. W. Cann, C. C. Richards, J. H. Killam, W. Law, B. B. Law, H. Crowell, Yarmouth, N.S., and C. Burrill, Weymouth Bridge, N.S., have applied for a charter as the New Burrill-Johnson Iron Co., Ltd., to carry on the business of the Burrill Johnson Iron Co., Ltd.; capital, $50,000.

R. S. Hodgins, Sydney, C.B.; F. Macdougall, Christmas Island, C.B.; Malcolm Macfarlane, Montreal; R. B. Van Horne, Sydney, C.B., and others have been incorporated as the Cape Breton Mnfg. Co., Ltd.; capital, $10,000; to make bricks; chief place of business, Sydney, C.B..

S. R. Poulin, Ottawa, Ont.; J. Bourque, Wright & Co., Hull, Que.; A. M. Calderon, architect; J. M. Cromwell, L. O. Joly, Ottawa; C. L. Graham, M.D., Hull, Que.; W. G. Mulligan, Aylmer; J. S. Allen, Ottawa; J. Piche, Hull, Que., are to be incorporated as the Gatineau Junction Brick Co., Ltd.; capital, $20,000.

The suit brought some time ago by the Colliery Engineer Co., of Scranton, Pa., conducting the International Correspondence Schools, against the American School of Correspondence, of Boston, Mass., was recently dismissed by Judge Lacombe, of the United States Circuit Court, the plaintiffs refusing to argue the case after several postponements of the trial.

In the town of Middleton, N.S., a sewage company has been formed to provide sewage disposal for a few subscribers to the company. The capital is $1,000. There are a great many towns where partial installations could be very beneficially undertaken in this way. The rights of the municipality in its own streets being of course properly protected.

The Syracuse Smelting Works, manufacturers of babbitt metals and solder, Montreal, have announced to the trade that they have bought the supply of raw material which they expect to use this year, and advise all their friends to place their orders promptly for any raw or manufactured goods they may require, as the works expects prices to be considerably higher.

Among this year's sales of the Goldie & McCulloch Co., Ltd., Galt, are one large Wheelock engine for the Midland Elevator Co., one for Collingwood Meat Co., one for the Beaver Portland Cement Co., Marlbank, Ont.; one for the Gutta Percha and Rubber Mnfg. Co., Toronto; three for the Linde British Refrigeration Co., Montreal; one for J. Oliver & Sons, Ottawa, Ont., and several others.

The Acetylene Manufacturing Co., of London, Ont., control the rights for a number of different types of acetylene gas machines. This company has put in a 300-light plant at the Walker House, Berlin; and a 380-light plant in a town in Manitoba. Mr. Stinson, of this company, has made some interesting experiments with acetylene gas as a fuel, which will be described in our next number.

Letters of incorporation have been granted to the Artesian Ice Company of Toronto, Ltd.; capital, $1,000,000; the provisional directors are: J. R. Barber, Georgetown; S. F. McKinnon, Dr. G. S. Ryerson and J. Flett, Toronto, and J. J. Long, of Collingwood, Ont. The company proposes to equip a factory for the manufacture of ice, with a capacity of over 100 tons per day, and to provide refrigerator and cold storage accommodation.

The Imperial Paper Co., Sturgeon Falls, Ont., it is announced has sold to Lloyds, of London, Eng., the owners of The Daily Chronicle, part of its concession from the Ontario Government for three-quarters of a million dollars. The purchase of a part interest in the company by the Lloyds means that the bulk of the output of the mills will be used in The Chronicle office and that of the other newspapers controlled by Lloyds. It is known that other great English papers are negotiating for the production of their paper supply in Canada.

We are informed that the net earnings of the New England Gas and Coke Co.'s plant for December amounted to $20,000. This showing was made on an average of less than 200 coke ovens in operation during the month, with an average price of but $2.57 received for coke and with but very small sales of gas. It is estimated that net earnings for January will reach $30,000 with an average of less than 250 ovens in commission. The company is gradually increasing its coke and gas output and it is expected that by the latter part of February its entire 400 ovens will be in operation, and that it will be supplying gas to Dorchester and Charleston in addition to Jamaica Plain and Brookline.—Boston Financial News.

Harrison Watson, Canadian section Imperial Institute, London, Eng., has had the following enquiries and invites replies: 1. A northern firm of importers wishes to hear of Canadian manufacturers of gig spokes, wheels, and hickory hammer shafts. 2. A Glasgow firm points out opening for Canadian nuts and bolts, and asks for names of manufacturers; American makers are finding a market here for same. 3. An Irish firm can contract for 50,000 sets spruce box boards cut to dimensions for manufacture of patent butter boxes. 4. A Midland manufacturer of anchors and chains is prepared to appoint a resident Canadian agent. 5. A Welsh firm wants immediate quotations for 150,000 spruce and white wood boxes cut to dimensions: Tops and bottoms, 18 x 11; sides, 18 x 9; ends, 10 x 9; quotations c.i.f. London; delivery before 31st May; cash, less 2½ per cent. against B.L. and insurance policy.

Electric Flashes.

The Ottawa Electric Railway Co. made last year a net profit of $85,280.37.

The Shelburne Power Co., Ltd., is applying for a Nova Scotia charter to develop power on the Rosemay river, near Shelburn, N.S.

A firm of electrical instrument and machinery makers in the United States is negotiating for premises in Brantford, owned by Wood Bros.

W. D. Snowball and others are being incorporated as the Chatham Electric Light Co., Ltd.; capital, $50,000; chief place of business, Chatham, N.B.

Jack & Robertson, electrical supplies, Montreal, have sent us a very handsome blotting pad, which combines the useful features of a desk calendar.

The Sherbrooke Gas & Water Co. intends to install new machinery in the lighting station the coming summer, which will increase the lighting capacity by 8,000 lights.

J. C. Eyres, of Woodville, Ont., president of the Victoria Telephone Co., which controls an independent system, with headquarters at Woodville, Ont., is building its line to Lindsay, Ont.

James McElliott, a former employee of the Lachine Rapids Hydraulic and Land Co., has entered an action claiming from it $5,000 damages for injuries received by coming in contact with a live wire while working in its service.

Montreal Street Railway proposes to put its electric wires under ground. The manager in a communication to the Road Committee of the Council, stated that the company had decided to expend some $200,000 on this conduit system.

The Electrical Maintenance and Construction Co., of Toronto, has opened a branch at 143 King street east, Hamilton, with a very attractive show room, under the local management of H. J. Wickens, son of A. M. Wickens, engineer of the Ontario Parliament Buildings.

St. Catharines, Ont., is asking the Ontario Government for power to raise $150,000, wherewith to acquire water powers for the development of electrical energy, for acquiring land, for the erection of buildings, etc., all of which is intended to induce manufacturers to locate in that city.

Major Gray, Government engineer, has reported in favor of, and the Railway and Canals Department has ordered a storage battery equipment to be put in, to swing the radial railway bridge at Burlington Beach, Ont., and also to light the canal in case of accident to the radial's supply wires.

Assistant Secretary Spaulding, of the United States Treasury Department, has announced that he would not decide the question of the dutiability of electricity brought into the United States from the Dominion of Canada. He admitted that he did not feel justified in taking up the matter at this time, and it is probable that the question will never be passed upon.

The London Cold Storage Co. is putting in a lighting plant, direct connected to Leonard self-oiling engines. The Electrical Construction Co., Ltd., London, Ont., has the contract.

The London, Ont., Electric Light Co. has just put in four new boilers, and the Berlin, Ont., Gas Co., one new boiler. The Kingsville Electric Light Co. is putting in a Leonard self-oiling engine.

A company to build electric launches is being organized in Hamilton, Ont., by S. R. Sintz, Chicago, and A. Ives, Detroit. The batteries will be built by the Volta Storage Battery Co., Hamilton, Ont.

The E. B. Eddy Co., Ltd., has contracted with Conroy Bros., Deschenes, for 800 electrical horse-power at $15. The use which is to be made of this large amount of power by the E. B. Eddy Co., has not been allowed to become public.

Application will be made to enable the Buffalo Ry. Co., or the Buffalo and Niagara Falls Electric Ry. to acquire the franchise and business of the Niagara Falls Park and River Ry. Co., the Clifton Suspension Bridge Co., the Queenston Heights Suspension Bridge Co., and the Queenston Heights Bridge Co.

The Hon. A. A. Thibadeau, R. Wilson Smith, G. H. Meldrum, Montreal; T. B. Stillman and H. Hall, New York, are being incorporated as the Electric Fire-Proofing Co., of Canada, Ltd.; capital, $300,000; headquarters, Montreal; to carry on the business of treating timber, wood and other substances so as to render the same fireproof.

The Hoeffner Refining Co., Hamilton, Ont., has placed an order with the Canadian General Electric Co. for two 1,500 amp., 120 volt generators, to be used for electrolytic purposes. These machines are to be direct-connected with Stanley motors, and the power will be supplied by the Cataract Power Co. from the DeCew Falls transmission lines.

At the annual meeting of shareholders of the Hamilton Electric Light & Cataract Power Co., Ltd., the officers and directors were elected as follows: Hon. J. M. Gibson, president; Jas. Dixon, vice-president; John Moodie, treasurer; John Patterson, secretary; J. W. Sutherland, John Dickenson, M.L.A.; J. A. Kammerer, Toronto, and Allan B. Forbes and Edward P. Smith, Chicago.

At the annual meeting of the Lachine Rapids Hydraulic and Land Co., a satisfactory statement was made, and the directors re-elected. The directors' report stated that the company's revenues had been dependent on private consumers hitherto but that they hoped to secure a city lighting contract at an early date. The lighting contract is now held by the Royal Electric Co.

Mayor Wilson, of Winnipeg, Man., has prepared a by-law voting $300,000 for the purchase of the plant now operated by the gas company, or the erection of a new one; also for the securing of the franchise for private electric lighting by the city. The Mayor states that the unqualified success of the city in handling the waterworks and the street lighting proves the utility of municipal ownership, and warrants the city in securing other franchises.

The Central Passenger Association has granted a special rate of a fare and one-third, on the certificate plan, from all points in its territory to Chicago and return, for delegates and friends attending the twenty-third convention of the National Electric Light Association, to be held in Chicago, Ill., May 22nd, 23rd and 24th. It is expected that the various other passenger associations will announce the same concession at an early date.

J. Patterson, J. Moodie, J. Dixon, W. W. Osborne and the Hon. J. M. Gibson, Hamilton, Ont.; J. Dickenson, Glanford, Wentworth county, Ont., and J. A. Kammerer, Toronto, have been granted incorporation to manufacture carbolite and products from its manufacture, and to utilize slag for its production, under the name of Carbolite, Ltd. The capital of this company is $1,000,000, and the head office is to be in Hamilton, Ont.

At the annual meeting of the Canadian General Electric Company the stockholders sanctioned the issue of $300,000 in new stock. The financial statement showed remarkable increases in business during the year. The annual report showed that the net profits for 1899 were $281,905, out of which $168,000 were paid in dividends, $60,358 written off machinery and other assets, $100,000 transferred to reserve fund, and $58,437 to profit and loss account. The reserve fund is now $140,000.

The Royal Electric Co. is supplying the electrical equipment for the Pratt & Letchworth iron works in Brantford, Ont.

The town council of Neepawa, Man., in accepting the electric light power plant recently installed by the Robb Engineering Co., passed the following resolution: "That this council has much pleasure in bearing testimony to the efficient manner in which J. F. Porter has installed the engine and boilers in connection with our electric plant, and that a copy of this resolution be sent to the Robb Engineering Co." Carried.

J. S. Clark, Ayr, Ont., vice-president and managing director of the Grand Valley Railway Company, which proposes to build an electric line from Port Dover to Goderich via Brantford, Paris, Galt and Berlin, says the company has behind it some well-known capitalists in New York and London, Eng., including D. W. McNair, J. Acton Lomax, Charles R. Sickles, Dr. Sanger, of New York; Hon. Jas. Roche, late of the Alaska Boundary Commission; and O. McNair, of the Warsaw Bank, Buffalo. Mr. Clark says that he completed arrangements for buying the charter of the Preston and Berlin Electric Ry. Co. He has also bought the toll road from Ayr to Paris, Ont.

At 11 o'clock on Tuesday night, January 9th, fire occurred in the power house of the St. Jerome Light and Power Co., St. Jerome, Que., which destroyed its electric plant. On Wednesday afternoon at 3 o'clock the Royal Electric Co. was instructed by the St. Jerome Co. to forward as quickly as possible, a 75-k.w. S.K.C. generator complete with exciter and switchboard: the whole went forward that evening, was received in St. Jerome Thursday morning at 10 o'clock, the destroyed plant was removed and the new one put in its place, and the lights turned on as usual at 5 p.m. on Friday, or 48 hours after the receipt of order by the Royal Electric Co. in Montreal, lights were again burning in St. Jerome.

Marine News.

The Yarmouth Marine Railway Co. has declared a seven per cent. dividend for the year.

F. Cormier, Moncton, N.B., has invented a rudder to be carried and shipped in case of accident to the regular rudder.

Thomas Henry, Canadian freight agent of the Northern Pacific Railway, has been appointed general traffic manager of the Richelieu & Ontario Navigation Co.

The St. Lawrence Terminal & Steamship Co., Ltd., is applying for incorporation to build wharfs, docks, elevators, etc., at Sorel, Que., or some other point on the Richelieu River.

G. R. Walker, formerly on the engineering staff of the Manchester Ship Canal, is now in Canada in the interest of the proposed Georgian Bay Canal.

The Cape Island Steamship Co., Ltd., is being formed for the purpose of doing business on the south shore of Nova Scotia, with Clark's Harbor as the chief place of business; capital, $10,000.

The Davis Dry Dock Co., Kingston, Ont., has the contract to build a steam yacht for the St. Lawrence Yacht Club. It will have a draught of not exceeding two feet, will be 65 feet by 13 feet beam, and 4 feet deep. The boilers will be Davis' water tube, carrying 200 lbs., the engine 8 inch by 8 inch cylinders. The speed is to be ten miles an hour.

A large and influential deputation from Port Hope, Ont., and Cobourg, Ont., recently interviewed Hon A. G. Blair, and asked that the Trent canal plans be altered so that instead of the canal being constructed from Rice Lake to Trenton, a distance of 64 miles, it be cut from Rice Lake to Port Hope, a distance of 10 miles.

R. Pickford, W. A. Black, G. W. C. Hensley, C. S. Pickford, W. A. Black, Halifax, N.S. (of whom Robert Pickford, William Anderson Black and George William C. Hensley are to be the first or provisional directors of the said company), are being incorporated as Pickford and Black Steamships, Ltd.; capital, $600,000.

The Davis Dry Dock Co., Kingston, Ont., has closed a contract with C. Lewis, Keewatin, Ont., to build the framework of a 70 foot passenger steamboat, all ready to set up at Keewatin.

It is announced that Mr. Petersen, of the firm of Petersen, Tait & Co., the firm which secured the contract for a fast Atlantic line from the Canadian Government, contemplates establishing a through steamship service for the carriage of grain from Lake Superior to England as soon as the deepening of the St. Lawrence canals to 14 feet of clear draught is completed.

A delegation of about twenty of the most prominent owners of lake vessels on the Great Lakes went to Washington recently, accompanied by H. D. Goulder, the attorney for the Lake Carriers' Association. Their object being to induce the United States Congress to take steps toward the formation, with Canada, of an international commission which should have charge of all matters affecting the water levels of the lakes. The reasons why they are active in the matter at this time are the completion of the Chicago Drainage Canal, the construction of the "Soo" power canal, and the proposed building of a dam in Niagara.

The plans for the improvements in the Red River, about fifteen miles from Winnipeg, call for a dam across the Red River 800 feet in length, a canal 1,900 feet in length, one set of locks 215 feet in length, and dredging in the river for a distance of some 400 feet. The lock will be 215 feet long, 45 feet broad and the solid concrete will be 38 feet deep, giving the locks a high water depth of 30 feet, while at low water the depth will be 11 feet. The gates of the lock will be of steel. The approach to the locks will be by a canal from a point on the west bank of the river, a distance of 1,500 feet. The canal will be 100 feet wide, and have a depth of 11 feet. The distance to the canal from the river will be of partly wooden crib work, filled in with stone and will be 200 feet in length. The canal extends 400 feet north of the lock to the river, which will be dredged to a depth of nine feet for about 100 yards. The dam to regulate the river will extend from the east side of the locks 800 feet, to a point on the east bank of the Red River. It will be of concrete, granite faced, 32 feet at the base and 18 feet 5 inches at the top. The dam is provided with seven piers and two abutments, and also with sluice gates. The piers and abutments can be used as the base of a service bridge and from this could be worked a system of shutters and movable frames, by which the height of the dam could be increased $12\frac{1}{2}$ feet. The bridge and shutters, however, will form a separate contract.

Mining Matters.

Alex. Dick, mining engineer, of Halifax, N.S., has moved to Toronto.

A valuable copper mine has been discovered at Mill Brook, Pictou county, N.S.

The Cordova Exploration Company's gold mine in Belmont, Ont., is also producing largely.

The proposed mill to be erected at Goldenville, N.S., to handle the quartz from the Palmerston, Mayflower and other properties, it is stated will be 100 stamps.

The Atlas Arsenic Company has been incorporated to do business in Belleville, Ont., with a capital stock of $750,000. The directors reside in Ohio.

The Canadian Gold Fields Company's mill at Deloro, Ont., is said to be turning out three tons of arsenic daily. The gold product is over $300 per day.

The annual meeting of the Canadian Mining Institute is to be held in Montreal on the 7th, 8th and 9th inst. The annual dinner will be at the Windsor Hotel on Friday evening, the 9th March.

A. McElwee, L. A. May, J. R. McDonald, H. G. Catlin, New York; M. Lodge and W. B. Chandler, Moncton, N.B., are applying for incorporation as the New Brunswick Cannel Coal Co., Ltd.; capital, $1,000,000.

An estimate made shows that there are close on a hundred companies employing over 2,000 men, engaged in development and mining work in the Lake of the Woods, Seine river and Manitou districts.

J. C. Calhoun, W. S. Logan, J. E. Calhoun, C. S. Daley, New York, and H. F. Puddington, St. John, N.B., are being incorporated as the Provincial Coal Co., Ltd.; capital, $1,000,000; chief place of business, Moncton, N.B.

M. J. Galvin, Buffalo, N.Y., manager of a blast furnace at Charlotte, N.Y., making foundry pig for magnetic iron ores of good quality which could be conveniently shipped from Belleville or Trenton, Ont., has recently made a search in central Ontario.

A decision of great importance to Quebec mine owners has been given by the Quebec Government regarding the exemptions from taxation of mining property. In 1890 exemption was granted the mines for ten years, and now an extension of the exemption for another ten years has been granted.

Iron ore yielding 64 per cent. of iron, and 7 per cent. of sulphur has been found near Ten-Mile Creek, some 22 miles up the bay shore from St. John, N.B. A lease, covering five square miles, has been taken by W. E. Skillen, St. Martin's, N.B., and he proposes to do development work.

Charles Howard, in behalf of himself and other stockholders of the Vermillion Mining Company, of Ontario, is suing the Canadian Copper Company, the Anglo-American Company, Stevenson Burke, C. W. Bingham, Henry McIntosh, Chas. Baird and J. B. Wright, executors of the Cornell estate, and all stockholders of the Canadian Copper Company, for $1,350,000 damages.

At the annual general meeting of the shareholders of the Cumberland Railway & Coal Company the annual reports of the company were presented by the secretary, H. R. Drummond, which were found highly satisfactory to the shareholders. The election of officers for the ensuing year resulted as follows: President, R. Cowans; vice-president, the Hon. G. A. Drummond; general manager, R. J. Cowans; secretary, H. R. Drummond.

Toronto and Nova Scotia capital has taken up the stock, $750,000, of the Port Hood Coal Company, and bonds to the amount of $750,000 have also, it is said, been issued. The company has the assurance of their engineers that the coal, amounting to 160,000,000 tons, is as good as the Sydney coal for steam. Work will begin in the early spring, and shipping will be made from Port Hood, 100 miles nearer the St. Lawrence ports than Sydney.

K. Ludloff, a German geologist, who, since last summer, has been living in Cariboo, B.C., in the interests of Russians who wish to replant the fir forest in Litonia, from British Columbia cones, has made a discovery of great importance. Herr Ludloff is in the camp on Woodpecker Island, in the Fraser River, a considerable distance above Quesnelle, where he has been collecting seeds. While doing so he is said to have discovered extensive deposits of gold-bearing conglomerate, intersected by veins of quartz, bearing gold and iron pyrites, similar to the gold in the Transvaal. He has also found deposits of red hematite, bearing free gold. This find is in the upper Fraser valley, about twenty or thirty miles south of Fort George. The formation is Archaean.

The Bureau of Mines has commissioned Prof. Courtney de Kalb, of the Kingston School of Mines, to prepare an exhaustive report on the salt industry in Ontario. The report gives a detailed account of the extent of the salt beds, present output, purity of brine and the various grades of commercial salt put on the market, methods of working and refining, with suggested measures for the further extension of the uses of the raw material in the manufacture of soda, soda ash and salts, soaps, etc., for home consumption. A detailed report on the peat industry in Ontario will be issued shortly by the Bureau of Mines, giving an account of the extent of the numerous available peat beds, analyses of raw and manufactured peat as made into briquettes by the Dickson compression patent, with the probable value of peat as a fuel for domestic and commercial purposes. This report will be of great interest to people in the coal and wood trade.

Railway Matters.

The Canada Atlantic Railway proposes to build a 5,000,000 bushel elevator at Sorel, Que., and is asking Government aid.

Owing to the large increase in business the C.P.R. has decided to erect new freight sheds in Toronto, at a cost of about $25,000.

The C.P.R. is said to be about to tunnel under the Nepean Point Park, Ottawa, to get a western entrance into the Central depot.

It is reported that the contract for 11½ miles of the Southern Railway, has been awarded to John W. McManus, of Memramcook, N.B.

Application is being made for an Act to authorize the Kingston and Pembroke Ry. Co., to extend its line from Renfrew, Ont., across the Ottawa river to Bryson, Que.

Incorporation is asked for a company to build a railway from Batchewana Bay on Lake Superior to the C.P.R., and to James Bay at or near the mouth of the Albany river.

Ce LeB. Miles, C.E., is making a survey for a line of railway from Bristol to Foreston, N.B., a distance of some fifteen miles. The road is intended to give the lumbermen in the vicinity of Foreston a means of transport for their lumber.

Application is being made by the Montfort and Gatineau Colonization Ry. Co., for leave to extend its line from the Great Northern Ry., near St. Canut, Que., to the Union Jacques Cartier Ry., near Montreal, passing through the counties of Two Mountains, Laval and Jacques Cartier, and connecting with the Union Jacques Cartier Ry.

It is said that a syndicate will make an offer for the purchase of the Kingston locomotive works, now in liquidation, and that among those concerned in the purchase are Mackenzie & Mann, of Toronto; James Hammond, of Fort William, and others. It is said that the Ontario & Rainy River Ry. would require the manufactures of the works for the next ten years.

An unexpected turn has been given to the discussion on Erie canal enlargement by the offer said to have been made by S. R. Callaway, president of the New York Central Railway Company. He has offered, it is stated, to transport free to shippers all the grain they may send across the State of New York for export if the State will pay its road four per cent. on the $60,000,000 proposed to be expended on the enlargement of the Erie canal. The interest on that sum would amount to $2,400,000 per annum.

John M. Nicol is the projector of the Quebec & Lake Huron Ry., the proposed air line between Georgian Bay and Atlantic tidewater. He said in a newspaper interview: "The line will be about 461 miles in a straight line through a new and unsettled portion of Canada, and would shorten the grain haul from Chicago and Duluth to the seaboard by fully 500 miles. The rail route would be about the same length as that from Buffalo to New York, saving all the lake distance between Georgian Bay and Buffalo. From Quebec to Liverpool is called 2,660 miles; from New York to Liverpool, 3,130 miles, giving us another 470 miles saved on the ocean, or nearly 1,000 miles less distance over our road to Liverpool from either Duluth or Chicago than over the present routes."

Very satisfactory progress is being made on the Inverness and Richmond Ry., which Mackenzie & Mann are building from Port Hastings to their mines at Broad Cove on the west coast of Cape Breton. The company owns extensive coal areas there, and the railroad is to carry the coal to Port Hastings on the Strait of Canso, which is to be the shipping point. Construction was started at the Strait in July last, and by December 1st the rails were laid over the first thirty miles. It is expected trains will be running over the whole line by December next. W. Z. Earle is chief engineer, and Ryan & Macdonell, of Montreal, are the contractors for the whole work, having as their manager Hugh Dokeny. The sub-contractors are, M. J. O'Brien, Renfrew, Ont., and Pegnem & Doheny, of Montreal.

LITERARY NOTES.

The Canadian Almanac for 1900 is issued as usual by Copp, Clark & Co., Ltd., Toronto. The historical diary contains more than usual, and a list of titled Canadians is given.

The Canadian General Electric Co., Ltd., has sent its friends a large wall calendar, which shows a number of views of the company's handsome new offices on King street, Toronto.

A graduates' magazine, "The Technology Review," has just been issued by the recently organized association of Class Secretaries of Mass. Inst. Tech. It is an octave volume of 140 pages, and of the best workmanship. The cover, designed by Hapgood, and printed on Army brown paper, is very handsome. The first number contains the announcement; a photograph with biographical sketch of President Crafts; articles on the Function of the Laboratory, by Prof. S. W. Holman, and on the Pierce Building, by Prof. E. B. Homer, the architect; reprints in fac-simile of early institute documents and letters—all in the first and more general half. The latter half, seventy pages, is given to news of the institute, of the undergraduate and graduate classes.

THE TORONTO TECHNICAL SCHOOL.

At the inaugural meeting of the Toronto Technical School Board, C. March was elected chairman for the year, and Ald. Hubbard vice-chairman. The committees were elected as follows:

School Management—D. J. O'Donoghue (chairman), L. J. Malone, R. Y. Ellis, A. F. Wickson, Ald. Urquhart.

Property—John Tweed (chairman), Ald. Hubbard, W. A. Langton, William Henderson and Thomas Cannon, jr.

Printing and Supply—Robert Glocking (chairman), James Wilson, Ald. Ward, William Rowe and A. M. Wickens.

Finance—C. Moseley (chairman), Mayor Macdonald, J. D. Allen, Ald. Leslie and F. B. Hayes. The treasurer's report for the year showed expenditures $12,294 and receipts $11,391.

CANADIAN PATENTS.

The following patents which are of interest to the engineering and mechanical trades have been recently granted in Canada. Full details of each device, together with the explanatory drawings, are published in the Canadian Patent Office Record, which are on file in our Toronto office, and may be examined by any of our readers who wish to call for that purpose.

No. 63,756—F. H. Pitkin and J. Thompson, Chicago, Ill.; a machine for making expanded metal, having a number of cutters arranged in converging series.

No. 63,757—The Ingersoll-Sergeant Drill Co., New York; a coal-cutting machine.

No. 63,762—C. de L. Rice, Hartford, Conn.; gear cutting machine.

No. 63,763—R. V. Sill, New York; an electrical heater.

No. 63,764—D. Crane, Ruthland, Vt.; a guard rail chair.

No. 63,769—W. H. Tobey, Tupperville, Ont.; water feed regulator for boilers, by means of a float.

No. 63,778—R. Lohnston, River Falls, Wis.; hoisting apparatus.

No. 63,793—C. F. Bancroft and P. F. Sullivan, Lowell, Mass.; systems of preventing collisions on electric railways in which a feed wire on a trolley line, provided with turnouts, has in each branch an insulated section, so that when a car passes one turnout the power is cut off from an approaching car.

SITUATION—A bright young man with a thorough education, technical in mechanics, desirable, can hear of an opportunity to his advantage by addressing "Farm Machinery," Sarnia, Ont. Want a young man of good habits and address, willing to grow up with a good business. Would be better equipped if familiar with farm and threshing machinery. No money required, but must be able to give best of references.

W. M. WATSON,

92 Dundas street, Toronto, whose articles upon sanitary topics in THE CANADIAN ENGINEER have attracted so much attention, leaves for Great Britain at the end of March. While in England Mr. Watson will make an exhaustive examination of the latest improvements in sewage disposal methods, waste water purification, etc. Mr. Watson will also be glad to undertake business commissions in line with his expert knowledge.

The Canadian Engineer

VOL. VII.—No. 12. TORONTO AND MONTREAL, APRIL, 1900. PRICE 10 CENTS $1.00 PER YEAR.

The Canadian Engineer.

ISSUED MONTHLY IN THE INTERESTS OF THE

CIVIL, MECHANICAL, ELECTRICAL, LOCOMOTIVE, STATIONARY MARINE, MINING AND SANITARY ENGINEER, THE SURVEYOR, THE MANUFACTURER, THE CONTRACTOR AND THE MERCHANT IN THE METAL TRADES.

SUBSCRIPTION—Canada and the United States, $1.00 per year; Great Britain and foreign, 6s. Advertising rates on application.

OFFICES—62 Church Street, Toronto; and Fraser Building, Montreal.

BIGGAR, SAMUEL & CO., Publishers,
E. B. BIGGAR, R. R. SAMUEL
Address—Fraser Building, MONTREAL, QUE.

Toronto Telephone, 1392. Montreal Telephone, 2589.

PHILADELPHIA AGENT: H. E. BURNETTE, 2036 N. 13th Street.

All business correspondence should be addressed to our Montreal office. Editorial matter, cuts, electros and drawings should be addressed to the Toronto Office, and should be sent whenever possible, by mail, not by express. The publishers do not undertake to pay duty on cuts from abroad. Changes of advertisements should be in our hands not later than the 1st of each month to ensure insertion.

THE BOSTON GAS WORKS.

BY CHAS. BAILLAIRGE, C.E., QUEBEC.

It may be interesting to the general public to say that during the late visit of the Canadian engineers to Boston on invitation of the engineers of that city, we visited the gas works of the New England Gas and Coke Co., which are so far ahead of anything else of the kind in any other city, both as to extent and novelty of arrangement, as to be well worthy of special mention.

I shall merely deal here with the economic features of the labor-saving appliances introduced to reduce the cost of production to 30 cents the 1,000 cubic ft. The coal used is of course of the bituminous or gas-producing kind. It is brought from Cape Breton, and costs the company but $2.63, delivered alongside the wharf at Boston. It consists solely of what is called slack or screenings of every degree of fineness up to and not exceeding an inch or less in size. A clam shell dipper from an elevated staging dips down into the hold of the vessel, scoops up a chaldron or more of the material, raises it to a height whence it is delivered from the clam shell into a trolley car. This car ascends along an inclined trolley way to a further height, which brings the coal immediately over the nest of retorts or furnaces into which it is to be delivered for caking or baking.

The retorts or furnaces are in nests of 50, and there are eight such nests or 400 ovens in all with a travelling feeder to each gang or batch of furnaces. Some idea may be had of the comparative size and capacity of the plant when it is known that while ordinary gas plants, like ours in Quebec or other Canadian and American cities, as well as those to be found elsewhere about the world, are but a few feet in length (6 to 10 feet), a couple of feet in width and as many in height, holding as they do a few barrow loads of coal; the Boston retorts are 30 feet long, 8 to 10 feet high, and 3 feet wide. Each of the eight nests is therefore, including the separating walls between them, some 200 feet in length, and on each side of this hive of furnaces runs an elevated rail along which the traveler passes, stopping on its way opposite the retort to be loaded. Its gates, three in number, form as many bin-like pockets in the wrought iron feeder, and after the corresponding hatchways to the oven have been removed, are simultaneously opened, delivering the coal or slack, as grain from an elevator, into the retort which has just been emptied of the residual coke of a previous charge and is ready again and red hot to receive the next supply; and when that has been baked for 28 hours and all the gas expelled, repeat the process day and night without cessation the year round.

These nests of retorts are mounted high or as if on stilts to allow of tunnels running longitudinally beneath them with parallel lines of piping, two to three feet in diameter with corresponding conduits above the retorts, the latter to receive the two kinds or qualities of gas manufactured; the so-called poor brand for culinary and heating purposes to be sold at 50 to 60 cents the thousand feet, and the richer sort for illuminating purposes at say a dollar or less the thousand feet.

Both of these gases have to be purified or cleared of their tar, sulphate of ammonia and other impurities, for which purpose they pass through the lower of the tubes thus mentioned on their way to large-sized buildings, where the gases are received in scores of large and tall iron cylinders and cooled in contact with cold water jets and coils which cause the residuals to condense, distil and run away into receptacles for the purpose, the one vessel or several of them delivering always into another or others at a lower level, and so carrying out the principle of labor-saving manipulation, by raising the coals on their delivery from the vessel to such a height that all other operations may be automatic and performed by gravity alone except where electric or steam power is made to intervene to lift the slack to its destination and work the travelers where the motion is horizontal. I have already said that the furnaces are raised above ground level, and they are so raised or built at a height sufficient to allow of their delivering their coke (which is what is left of the coal after the gas has been expelled therefrom by roasting or heating in air-tight receptacles), at a height still sufficient for final delivery into the railway cars for commercial purposes.

The operation, which is the most novel, striking,

and so to say, sensational of the whole process of gas making, is as follows: Along each side of the row or range of furnaces is a line of railway. At each end of each retort is an iron door. When, as already stated, the coal has been cooking in a red hot or incandescent state for 28 hours, more or less, according to quality, the door at the rear end of the furnace is opened; a powerful hydraulic ram moving on wheels along the rear track, just alluded to, thrusts a strong iron plate adapted to a movable axle or horizontal plunger against the rear face or end of the mass of coke to be expelled. This prism of red-hot coke, if nothing were provided at the opposite or front end to receive it, would of course fall to the ground, the front portion as pushed forward breaking off from that behind it in the same way as the protruding portion of a glacier breaks away from the parent stock and falling into the sea floats away in the shape of so many icebergs. It would then have to be removed by shovels and hand labor and thus slowly charged into the railway trucks ready to receive it. But anything like such delay would jeopardize the whole process of cheap gas production. No, there is no such slow-going process of manipulation tolerated here; everything has to be done in a minute or two, and so it is—the speeding of the coal on its way from the vessel to the works is the delay of a minute or two—the feeding of the retort is done in a minute or less, and now the emptying out of its contents has to be as speedily performed. The ram alluded to thrusts out its thirty-foot arm and pushing hand in a minute of time, or not much more, and to receive the falling mass, a railway truck, platform or box car is made to run alongside, receives the red-hot mass as it disintegrates, into an iron cradle or receptacle of the full length of the car and say some 8 feet in breadth, tilted up high on the receiving side and at such a height from the ground on the opposite side as to be able, while passing alongside an empty railway truck on a siding, to dump its contents thereinto by a simple and partial motion around its rotating axle, as with a dumping cart or snow van; the red-hot coal coming from the furnace having water thrown upon it as it falls into the first car, and from the one into the other, to reduce its heat and render it bearable by the manipulators who have a hot time of it during the process.

The gas holder at these works is over 198 feet in diameter; its height is 229 feet, partly above and partly below ground, as usual, working in four lifts in the way that the first eye tube of a telescope pulls out the second, and the second the third. Its capacity is five millions of cubic feet. The works are now using daily about 1,500 tons of coal, the output being some 4,000,000 feet of rich gas, 5,000,000 feet of poor gas, 1,100 tons of coke, 75 tons of tar, and 20 tons of sulphate of ammonia.

The mains are now laid, the larger or principal ones for the conveyance and subsequent distribution of the poorer gas for heating purposes, and when turned on and used for domestic cooking and heating, ashes and the ash bin will become a thing of the past, and no more space in cellars or tenements will have to be reserved for or taken up by the usual yearly requirements of from 10 to 20 tons of coal. Nothing thereafter but the essence of the coal will be used and the gas for heating will be turned on or off as for illuminating purposes. It is a foreshadowing of my conclusion of ten or twenty years ago, that it must come to this in the end.

For THE CANADIAN ENGINEER.

BROCKTON, MASSACHUSETTS, SEWAGE DISPOSAL WORKS.

BY C. H. RUST, CITY ENGINEER, TORONTO.

On Friday, February 2nd, 1900, several members of the Canadian Society of Civil Engineers, accompanied by Mr. Barnes, city engineer of Medford, went to Brockton, Mass., to visit the sewage works. We were met at the station by Mr. Felton, city engineer, who went with us to the works. Brockton has a population of about 40,000, the average quantity of sewage per day being between 600,000 and 700,000 gallons. The sewage is pumped to a height of thirty feet, the main being three miles in length. The separate system is in use. The sewage is treated by intermittent filtration, the municipality owning about thirty acres. About fifteen acres are used at present of which seven and one-half are under-drained. The filter beds are one acre each. At present they are experimenting with stale sewage, the sewage being allowed to stand in the mains for some hours, acting somewhat as a septic tank. The result appears to be very satisfactory. The effluent, which is discharged into a cranberry marsh, through which flows a small creek, had every appearance of being more pure than the water in the creek. There is a well-equipped chemical laboratory at the filter beds. Mr. Felton explained that they were now furrowing the beds as being more satisfactory.

The annual cost of labor, including the services of a chemist, will this year be about $2,500 or $2,600. Only two laborers are employed, who live close to the beds. At present corn is grown and last year about $300 worth was sold. Fruit trees have also been planted and appear to be flourishing. At the time of the visit the weather had been very cold and ice had formed on the surface of the beds, but the working of the beds was not interrupted in the slightest degree. At Brockton, experience shows that the stale sewage is easier to filter than the fresh. The rakings from the sludge beds are now eagerly sought for by farmers in the vicinity.

SOUTH AFRICA, ITS PEOPLE AND TRADE.

CAUSES OF THE BOER WAR.

ARTICLE V.

(Continued from last issue).

When the question of sending a Canadian regiment to help Britain in South Africa was discussed lately, one of our politicians asked, "Why should we entangle ourselves in Great Britain's foreign wars, and why should we spend our money and blood in those far-away places?" In the first place, this is not a foreign war. From an Imperial standpoint it is very much a domestic war. It is not merely a matter of the ill-treatment of our fellow-subjects in the Transvaal, but whether we are to abandon our fellow-colonists in the Cape and Natal to a misrule comparable only to that of the Turks in Armenia—whether, in short, we are to lose or hold our Empire in South Africa. The Cape, be it remembered, is the halfway house to India, to our possessions in China, to Australasia, and to the smaller islands of the Eastern Hemisphere. If it had not been for the possession of the Cape and the ability of Great Britain to send reinforcements thence to India, during

the great mutiny, she would have lost her Indian Empire then. If it was vital to Britain then, the Cape is doubly so now, when Australia has become a daughter nation, and other Eastern lands have increasing claims upon her. South Africa is, in fact, the key of the Empire in the Eastern, as Canada is in the Western, Hemisphere. Moreover, knowing what the military ambitions of the Transvaal are, and what that state would certainly do the moment Britain became engaged in a foreign war, could we, as members of the British Empire, tamely watch our sister colonies of Natal, the Cape, Rhodesia, etc., overrun and reduced to the slavery which would be their lot under Boer rule? If we did our own turn would come, and the Empire would be dismembered limb by limb.

To descend to a lower plane, Canada has a strong commercial reason for seeing British ideas prevail in South Africa. Our manufacturers are now beginning to seek foreign markets, and under the rational rule of Great Britain, a large trade development awaits Canada there. South Africa is the counterpart of Canada. We consume large quantities of goods she has to sell, such as merino wool, hides, and sub-tropical products, while she imports largely of manufactured goods, such as furniture, boots and shoes, textile fabrics, stoves, hardware, machinery, and other manufactures, which we wish to sell. South Africa is essentially a non-manufacturing country, and the United States, having studied the conditions there through its consular agents, has already built up a big and rapidly-increasing trade. Not many years ago the exports of the United States to all Africa amounted to but a few thousand dollars annually. In 1898, the shipment of United States goods to British and Portuguese South Africa alone, amounted to over $16,000,000, the increase over 1897 being a growth of over $1,480,000, or at the rate of nine per cent. These exports consisted of foodstuffs, books, cotton goods, leather goods, and a long list of manufactured articles, such as agricultural implements, bicycles, hardware, sewing machines, typewriters, carriages, furniture, canned goods, lumber, etc. In almost every one of these lines, Canada is able to compete with the United States. Here and there, it is true, some Canadian manufacturer has already entered the market, but, as a rule, the Canadian exporter is still asleep to the possibilities of that land. It is time we woke up to this, for the trade connections ought to be as close as the political fraternity, and the sending of the Canadian regiment will tend to strengthen the bonds, both in a commercial and political sense. Further reference to the trade of South Africa will be found in the section of "miscellaneous facts."

As for our duty to Great Britain, as citizens of Canada, when we reflect that in the past twenty years the Mother Country has spent over $55,000,000, according to J. Castell Hopkins, on the defences of Canada, we owe it to our own self-respect to see that at least some of this is repaid. As citizens of the Empire, does it not seem a duty to defend it when any vital part of that Empire is threatened?

What will be the outcome of the war? In all probability the union of the present colonies and states in a confederation, in principle like that of Canada, but differing in details, to accord with the varying conditions. When the British and Dutch have got together, after the present conflict, they will see, by a study of their past history, that the policy of mutual hate, distrust and intolerance, is a policy that must mark their land with ruin; but the policy of good-will among the white races will make South Africa what its climate and latent resources fit it to become—one of the most delightful in the world. This much is certain, that in the settlement to be made, the British Government will not revisit upon the Boers the injustice under which the Uitlander population has groaned for the past eighteen years, but will see that there shall be absolute equality of rights among the white races, and fair, just treatment of black and white from the Cape to the confines of British Central Africa.

MISCELLANEOUS FACTS RELATING TO SOUTH AFRICA.

The following miscellaneous information, relating to South Africa, will be of interest to the reader in studying the present conditions:

Mr. Garrett, a well-informed Capetown journalist, estimates the white population as follows, distinguishing the Dutch from the British in the same table:

	Dutch.	British.	Total White Population
Cape Colony and Bechuanaland	265,200	194,800	460,000
Basutoland	300	350	650
Orange Free State	78,100	15,600	93,700
Natal and Zululand	6,500	45,500	52,000
Transvaal	80,000	123,650	203,650
Rhodesia	1,500	8,500	10,000
Total	431,600	388,400	820,000

John Noble's "Handbook of the Cape and South Africa for 1893," gave the area and white and colored population of South Africa, as follows:

	Area sq. miles.	White population.	Colored population
Cape	221,311	376,987	1,150,237
Natal	20,461	42,759	512,817
Pondoland	3,869	100	200,000
Zululand	8,900	548	145,336
Amatongaland	5,300	.....	80,000
Basutoland	10,293	578	218,324
British Bechuanaland	60,777	5,284	55,122
Bechuanaland Protectorate	386,200	500	110,000
Brit. Mashonaland (Rhodesia)	150,000	2,500	250,000
Orange Free State	48,326	77,716	129,787
Transvaal	113,642	160,000*	649,560
Swaziland	8,000	500	63,000
	1,037,070	667,472	3,564,183

For the trade tables which follow, the writer is indebted to the "British and South African Export Gazette," an ably conducted paper, published in London in the interest of South African commerce.

The aggregate trade, both imports and exports, of South Africa in the past five years, amounted to about £220,000,000 sterling. This includes an approximate calculation of the 1898 figures. Of this total, the imports of oversea goods represented a sum equal to £108,855,340, and these were imported into South Africa through its several ports in the following proportions:

Ports of Cape Colony	£ 77,623,022
Ports of Natal	21,348,222
Ports of Delagoa Bay	9,883,196
Quinquennial total	£108,855,340

Of this handsome total Great Britain's share in the export of

* A white population of 300,000 was generally credited to the Transvaal up to the time of the recent troubles, of which from 70,000 to 90,000 was accorded to Johannesburg.

purely British and Irish goods and manufactures was represented by £62,801,203, and that of the British possessions by £5,799,783, or together £68,600,986, the balance, in round numbers, of £31,000,000, being the contribution of all other countries. The progressive yearly accretions by which these totals have been reached are shown by the following tabulations:

GREAT BRITAIN'S QUINQUENNIAL SHARE OF SOUTH AFRICAN TRADE.

1894	£ 8,766,828
1895	11,167,995
1896	14,798,430
1897	14,648,162
1898 (approximate)	13,419,848
Quinquennial total	£62,801,223

QUINQUENNIAL SHARE OF BRITISH POSSESSIONS.

1894	£ 605,561
1895	997,558
1896	1,261,504
1897	1,235,160
1898 (approximate)	1,700,000
Quinquennial total	£ 5,799,783

QUINQUENNIAL SHARE OF FIVE PRINCIPAL FOREIGN COUNTRIES.

1894	£ 1,414,565
1895	2,188,247
1896	4,432,428
1897	4,503,366
1898 (approximate)	5,500,000
Quinquennial total	£18,028,606

The relatively large proportion of a little over one-third of the total trade of South Africa which falls to foreign countries is explained by the fact of the heavy imports in recent years of grain, foodstuffs, and live and dead meat, necessitated by the drought and rinderpest and the devastations of locusts, which have afflicted her agricultural and herding industries for several years past. The extent of this huge oversea buying of British and foreign goods would manifestly be impossible unless South Africa possessed purchasing "media" for their acquisition. These are furnished her by her rich and practically inexhaustible stores of native gold, diamonds and other minerals, wool and other raw products.

The imports into the Cape Colony amounted approximately to £16,845,955 at the end of 1898, having made an average advance of over £5,000,000 since 1894—in fact, if compared with the figures for 1897, an actual advance of £7,000,000. In the same quinquennium Natal's imports showed progress from £2,316,596 to approximately £5,127,887, or an enhancement at the handsome rate of 121 per cent. This was even more than the relative progress of either the South African Republic or the Cape Colony, the latter gaining only 49 per cent., and the former 61 per cent. on the earliest year. It is noteworthy that the former's total—£54,332,227—is nearly exactly half of the aggregate of South African imports, and shows the overweighting factor the Republic forms in the commercial expansion of the sub-continent. The appended comparison of the percentages of progress of the trade of the past quinquennium of India, Canada, Australia and the colonies of the Cape Colony, Natal, and Rhodesia, and the South African Republic is given by The Gazette:

QUINQUENNIAL PROGRESS OF OTHER BRITISH POSSESSIONS AS COMPARED WITH SOUTH AFRICA.

	Rate of Quinquennial Progress.
South Africa—	
Natal	121.0 per cent.
Rhodesia	94.0 per cent.
South African Republic	61.0 per cent.
Cape Colony	49.0 per cent.
Other British Possessions—	
Australia, Tasmania, New Zealand, Fiji	40.0 per cent.
Dominion of Canada	8.0 per cent.
India (including Burmah, Straits Settlements, and Ceylon)	per cent. 0.2 per cent.
Average for South Africa	71.0 per cent.
Average for other British Possessions	16.0 per cent.

The ratio of progress in imports alone of South Africa compared with those of our chief colonies and dependencies—India, Australia and Canada—is not less instructive. As against a total for South Africa of £108,000,000, Canada has only an import volume of £26,000,000* to show, and Australia of £97,000,000; while the vast continent of India only surpasses South Africa by her £157,000,000 of imports in the five years.

W. Bleloch, in a paper recently read before the Geological Society of South Africa, confirms the theory first propounded by Dr. F. G. Becker, of the United States Geological Survey, that the Witwatersrand gold-bearing rocks are due to the formation of a series of sub-shore deposits banked up by ocean currents and waves against a sloping shore. At first sight this is only of interest to geologists and mining experts. If, however, it should be confirmed by subsequent tests, it will have far-reaching effects upon the Rand gold mining industry, and equally upon commerce. For instance, payable reefs should exist under the major portion of Johannesburg itself, whilst the Main Reef series would be found underlying the overlaps of more recent beds from Vlakfontein to Venterspost, thereby opening up an enormous area of country for mining purposes, and extending the life of the Rand as a gold producing centre far beyond the 100 or more years already predicted for it by the world's leading experts. It is estimated by Frederick H. Hatch, in the "Engineering Magazine," of New York, that within the next five years the number of stamps in the gold mining district of the Witwatersrand will be increased to over 12,000. The average duty of a stamp here is 1,500 tons per year, or a total of 18,000,000 tons, which, at the present grade of 9 to 10 dwts. of fine gold, or 40s. per ton, would give £36,000,000 sterling per annum.

The coal deposits of the Transvaal are estimated at 235,000,000,000 tons, or 37,000,000,000 tons over those of the coal beds of Great Britain.

Since the first edition of this pamphlet was issued, the writer has received a copy of a New York publication, giving a summary history of the Transvaal. The compiler of this history, which is evidently derived from Boer sources, says that "in 1881 the suffrage in the Transvaal was open to anyone who had lived in the republic two years: but when the British part of the population, which had been voting and holding offices, refused to take part in the defensive war against the Kafirs, on the plea that they were British subjects, and so could not be drafted into service, the Boers, who then far out-numbered the foreigners, passed a law making a renunciation of all other sovereigns a pre-requisite to citizenship in the Transvaal."

This statement of the case, which contains as many inaccuracies as could possibly be crowded into a single sentence, is another illustration of the way in which the Boer authorities have tried to make black appear white to the uninformed outside world. Without going into all the misconceptions in this statement, it will be sufficient to point out that when the Boers undertook their most unjust and unprovoked war against the Swazis, an independent tribe dwelling beyond the Transvaal boundary, they proceeded to commander British sub-

NOTE.—The author has to thank Mr George Hague, General Manager of the Merchants Bank of Canada, for calling attention to a mistake in the above figures by which the S. A. *Gazette* has done a great injustice. Mr Hague says, "In that admirable little pamphlet—(I hope you have sold thousands of them), there is a curious mistake about the imports to Canada. There imports are given as £26,000,000 for five years, whereas the actual imports for one year only—the last of the quinquennial period—amounts to that sum. The total for the five years is over $520,000,000, or £107,000,000, and the rate of increase is not 8 per cent but 37 per cent. The Transvaal imports include the prodigious sums spent in cannon, rifles and other war material.

jects and other Outlanders. The British subjects in particular stoutly objected; "No," they said, "as long as we are denied the rights of citizenship, we shall refuse to fight the battles of the Transvaal. Give us the burgher's rights, and we shall gladly fulfil the burgher's duties; but while we are denied the franchise, we are not going out to fight under the status of galley-slaves." This was the only attitude that a self-respecting man could take, yet the Boer Government actually forced a number of British subjects to go to the front and serve without compensation, and the outrage would have been carried to greater lengths if the British Agent had not made an emphatic protest in the name of the Imperial Government. In the face of these facts, the Boer Government has tried to twist this question completely round and to make it appear that the franchise was afterwards refused because British subjects would not fight for the Republic; whereas, it was just because they were denied the burgher rights that they declined to do military service, especially in a war undertaken to despoil an unoffending tribe.

While most of the habitable areas of North and Central Africa are not favorable to Anglo-Saxon colonization, but are only capable of government on the plan of British government in India and Egypt, almost every region of South Africa possesses a climate in which European settlers thrive, as the experience of British and Dutch for over a hundred years has amply shown. There are several varieties of climate in South Africa, but generally speaking, their nearest parallel on the American continent is to be found in Northern and Southern California and Colorado. Along the coast of Natal and the eastern coast of the Cape we have all the sub-tropical products, such as bananas, pineapples, oranges, tea, coffee, cotton, etc., while in the midland regions of Natal and the Cape we find some of these products, with peaches, pears and many of the fruits and grains of the temperate zone; and again, on the plateaus and plains of Upper Natal, the elevated lands of the Cape, the Free State and the Transvaal, we find the fruits, vegetables and grains of England or Canada. Again, in the lowlands of the Transvaal and neighboring states we have a warmer climate, and some tropical products, like the middle and lower districts of the Cape and Natal. Being in the southern hemisphere South Africa has its summer when Canada has its winter, and instead of spending Christmas round the fireside the Natalians and Cape Colonists celebrate that season by picnics and outdoor festivities. Although two or three crops of vegetables and of some kinds of grain can be raised in a year, and vegetation never ceases, except in prolonged droughts, there are properly only two seasons in most parts of South Africa—the rainy and the dry

—The report of the annual meeting of the Association of Ontario Land Surveyors, containing portraits and biographical sketches of the new officers, has been crowded out of the present issue, but will appear in May.

—The numerous manufacturers, especially those in the machinery line, who have for years had increasing cause of dissatisfaction with the drift of things at the Toronto Exhibition, have all reason to thank J. O. Thorn, of the Metallic Roofing Co., for taking up their complaints and fighting for their interests against that clique in the board of directors who are responsible for the moral degeneration of Canada's great show. Many individual complaints have been made to the "Canadian Engineer" that the circus and peanut departments have received the lion's share of attention, while the reasonable requirements of the manufacturer have been ignored. A large number of foreigners will come over to Toronto from the Pan-American Exhibition at Buffalo next year, and there is yet time to make the reforms needed for a really good exhibition in 1901. If those of the exhibition directorate who really care for the future of this institution could see the stacks of letters Mr. Thorn has received, they would cease their silly attempts to laugh down these complaints, and would come down from their kopjes at once. We do not suppose there is any general desire to depose Mr. Hill. He is an energetic and capable exhibition man, and with a different set of men to work with would no doubt make the reforms needed to redeem the character of the show. As an example of the feeling of manufacturers in this matter we understand that nearly all the makers of agricultural implements have agreed to withdraw from the exhibition altogether, though we suppose they would reconsider this step if the directors made a "right-about face."

THE USE OF BOILER COMPOUNDS.*

BY ALBERT A. CARY.

(Concluded from last issue).

Next, turning to the sulphates of lime and magnesia, we find them very soluble, dissolving in water direct, without requiring the presence of carbonic acid or any other foreign agent. The amount of sulphate of lime which can be dissolved in one United States gallon of water at different temperatures may be appreciated by examining the following table:

At 32° Fahr. 120 grains per gallon.
At 95° Fahr. 148 grains per gallon.
At 212° Fahr. 127 grains per gallon.
At 250° Fahr. 9 grains per gallon.
At from 260° to 302° Fahr. it is practically insoluble.

This latter temperature (302 degrees) corresponds to 55 pounds gauge pressure, and, therefore, when water is thoroughly boiled at this temperature, practically all of the sulphates will be precipitated. The crystals of sulphate of lime will be found to be long and needle-like, and also very heavy and possessing cement-like qualities, so they fall rapidly, and, mixing with the precipitated carbonates, they bind them together into a hard, resisting mass, difficult to remove with even hammer and chisel, if they form a considerable proportion of the scale. It is here where the active agent in the compound is supposed to take effect, and by referring to the reaction given above—in the formulae (a) and (b)—when the carbonate of soda is used, it will be seen that the sulphates of lime and magnesia are changed into carbonates, which are precipitated and form a scale varying from a more or less porous, friable crust to a "mush" or mud. The sulphate of soda which is also formed by this reaction is extremely soluble, remaining in solution at nearly all boiler temperatures and forming no scale, unless allowed to concentrate, and this is prevented by "blowing off" occasionally

The tannin matters, referred to above, are obtained from various vegetable sources containing tannic acid, such as certain kinds of sumac, gallnuts, catechu (or cutch) bark, etc. Tannin is generally combined with soda to form the tannate of soda for use with boiler waters to keep the deposit soft or in suspension. Its action is supposed to be as follows: The tannate of soda decomposes the carbonates of lime and magnesia as they enter the boiler, and tannates of lime and magnesia are precipitated in a light, flocculent, amorphous form and are long kept in suspension by the circulating currents of water, until they finally are deposited in a loose, mushy mass in that part of the boiler where the circulating currents are the weakest or possibly in the mud drum. When the above reaction takes place the carbonate of soda is formed, which reacts with any sulphates that may be present, as has already been described. The use of tannic acid in the boiler cannot be recommended unreservedly as it will attack the iron as well as the carbonates (although, of

*Reprinted from the American Machinist

course, more slowly), and anything that will corrode the boiler itself certainly cannot be desirable. To test this, anyone can obtain a few cents' worth of tannic acid from the druggist, and by dissolving the crystals in a glass of water and adding some iron filings, a very fair quality of ink can be made, due to the action of this acid on the iron.

In practice, the reaction of caustic soda ($Na_2O_2H_2$) with the sulphates seems to be more active than when the carbonate of soda is used, the probable reaction being as shown thus:

Sulphate of Lime	and	Carbonic Acid	and	Caustic Soda
$CaSO_4$	+	CO_2	+	$2NaOH=$
		form		
Caustic Lime	and	Carbonic Acid	and	Sulphate of Soda
CaH_2O_2	+	CO_2	+	Na_2SO_4

The carbonic acid used in this formula results from the precipitation of the mono-carbonates from the bi-carbonates, as has been explained.

The secondary reaction from the result just arrived at is as follows:

Caustic Lime	and	Carbonic Acid
CaH_2O_2	+	$CO_2=$
	form	
Carbonate of Lime	and	Water
$CaOCO_2$	+	H_2O

The use of caustic soda may be considered less desirable than the use of the carbonate of soda for several reasons. In the first place this present in excess will cause violent foaming in the boiler, and with this foam often the light precipitated matter in the boiler will be carried along steam pipes into valve seats, gauge glasses, etc. It will also attack and cause corrosion of the brass fittings, and it is also dangerous to handle, owing to its caustic qualities, burning the flesh painfully wherever it comes in contact. An excess of carbonate of soda may also cause foaming in the boiler, but not as violent as when caustic soda is used.

Sal ammoniac (i.e. ammonium chloride) (NH_4HCl) is most undesirable for use in a boiler, due to the liberation of hydrochloric acid (HCl) following its introduction into the boiler. This acid leaves the boiler in a vaporous form, with the steam, corroding boiler, piping and nearly everything it comes in contact with. There are other "compounds" falling under this classification, of known chemical composition, which are more satisfactory than those named above, such as bi-sodium phosphate and tri-sodium phosphate, the latter being obtainable in both a hydrous and anhydrous state. The latter is less bulky and its reaction with the sulphate of lime is shown by the following formula:

2 Parts		3 Parts
Tri-Sodium Phosphate	and	Sulphate of Lime
$2Na_3PO_4$	+	$3CaSO_4=$
	form	
		3 Parts
Phosphate of Lime	and	Sulphate of Soda
$Ca_3(PO_4)_2$	+	$3Na_2SO_4$

The phosphate of lime, after this reaction, falls, forming a slushy mud, making at the most a very weak crust, while the sulphate of soda remains in solution, as previously described. The fluoride of sodium is another "compound" of known composition, which has also proved satisfactory, especially when much sulphate of magnesia is present; its reaction with the sulphate of lime being as follows:

2 Parts of		
Fluoride of Sodium	and	Sulphate of Lime
$2(NaF)$	+	$CaSO_4=$
	form	
Fluoride of Lime	and	Sulphate of Soda
CaF_2	+	Na_2SO_4

The fluoride of lime precipitated in the boiler behaves much like the phosphate of lime just described, while the remaining sulphate of soda is found in solution, as stated above.

Our second division of compounds includes a class of materials which are gradually falling into disuse due to their proved undesirability. They thicken and foul the water in the boiler and coat its surfaces with non conducting material, and occasionally the precipitated scale making matter, along with this class of compound, will obstruct the passage of heat through the boiler plates, so as to cause bagging and burning. In this class we find slippery elm, ground bones, horns and animals' hoofs, potatoes, dextrine, and starch, animal fats and animal or vegetable oils. As rapidly as the scale-forming crystals are precipitated from the feed water, they fall into this sticky cooking fluid and become coated with its filth, and they finally fall to the place of deposit, where they remain in a mushy, separated state until the organic matter chances to be burned out, when they will form into a loose, friable scale.

A surface blow-off or skimming device is most essential to reduce the evil, when this class of compound is used, and the bottom blow-off cock should also be opened very frequently.

We now come to our last division of this subject. The principal substances used for this third class of compounds are petroleum and kerosene. Petroleum oil has much more of the enveloping quality described under the last (or third) classification than the kerosene. Besides producing this effect on the scale matter, both have an active rotting effect on the scale already formed, the kerosene in this case being superior to the petroleum. Crude oil should never be used, but a carefully refined oil, which has been deprived of its tar or wax, should be selected for this purpose, as these cause the formation of a tough, impervious scale productive of bagged sheets and collapsed flues. Petroleum or kerosene should be fed to the boiler with the feed water, drop by drop, through a sight-feed apparatus similar to those used to feed oil to the cylinders of engines. There are several forms of this apparatus on the market. Under no consideration should large amounts of these oils be fed to a boiler at one time, as it must be remembered that the more volatile portion of the petroleum will be quickly distilled off in the hot boiler, leaving the least efficient portion behind, while the more volatile kerosene will be vaporized very quickly, before it has time to thoroughly mix with the water.

Where hard scale has formed in a boiler, it is most effectually treated by giving it a coat of petroleum or kerosene, to partially dissolve or rot it. These may be applied with a brush or squirted on, but an easier method of application is to first fill the boiler with water above the line of scale deposit and then pour the oil on the surface of this water, and let the water gradually run out of the bottom of the boiler, thus leaving the oil behind clinging to the whole interior surface. As stated above, kerosene is the most effective in destroying the tenacity or coherence of this deposited scale, but this method of using either oil is not without attending danger, on account of the explosiveness of the vapor given off; so great care must be taken to have no lights in the vicinity of the boiler under such treatment, as men have been seriously injured by this lack of prudence. The treatment of feed waters inside of the boiler has been a practice of many years' standing, but in the light of recent progress is not to be commended. A boiler certainly has all that it can reasonably be expected to do when it is generating steam, without being called upon to perform the functions of a chemical laboratory. Everyone knows that when a new boiler is started it "steams lightly" and is most economical in its use of fuel, but generally after it has been in service for some time harder firing is necessary and larger fuel bills appear. Following this reasoning, I would ask if it is not far more sensible to keep the boiler constantly up to its original state of efficiency by preventing the scaling and corrosive agents from entering it, rather than accepting such evils and trying to correct them after they have occurred?

The external method of treating feed water, chemically or mechanically, is being adopted by many progressive plants in this country; and in this, I am sorry to say, Americans are far behind the English, French, Germans, Belgians and Austrians, in whose countries the external treatment has been largely and most successfully practised for many years. There are, of course, plants where the internal treatment of feed water is an enforced necessity, owing to surrounding conditions or lack of funds necessary to install apparatus for external treatment, but as such apparatus has invariably proved to be an excellent investment, it should receive careful consideration from all steam users.

Before closing I feel that I must add something in the way of warning to the users of boiler compounds. Owing to the unfortunate fact that boiler users have, as a general thing, been too busy to give this important matter of scale and corrosion a proper amount of study, they have become the victims of

more imposters than exist in almost any other branch of trade. The boiler quack comes along with his remarkable boiler compound, fluid or special apparatus, and without the slightest knowledge of the character of the impurities held in your boiler feed water, he offers his panacea with a long list of letters of recommendation, written often by the heads of concerns who are far better acquainted with the financial end of their business than with the steam plant equipment. These gentlemen generally depend upon what their engineer or other employees tell them. The writer knows of not a few cases where the unscrupulous vendors of certain compounds share their profits with these engineers, firemen or other influential employees, which they can well afford to do, as the stuff they sell seldom costs a fifth of what they get for it. These unscrupulous people, their methods and their wares have been "shown up" from time to time in the technical and trade papers, and they have not escaped the well-directed fire of the Hartford Steam Boiler Inspection and Insurance Company.†

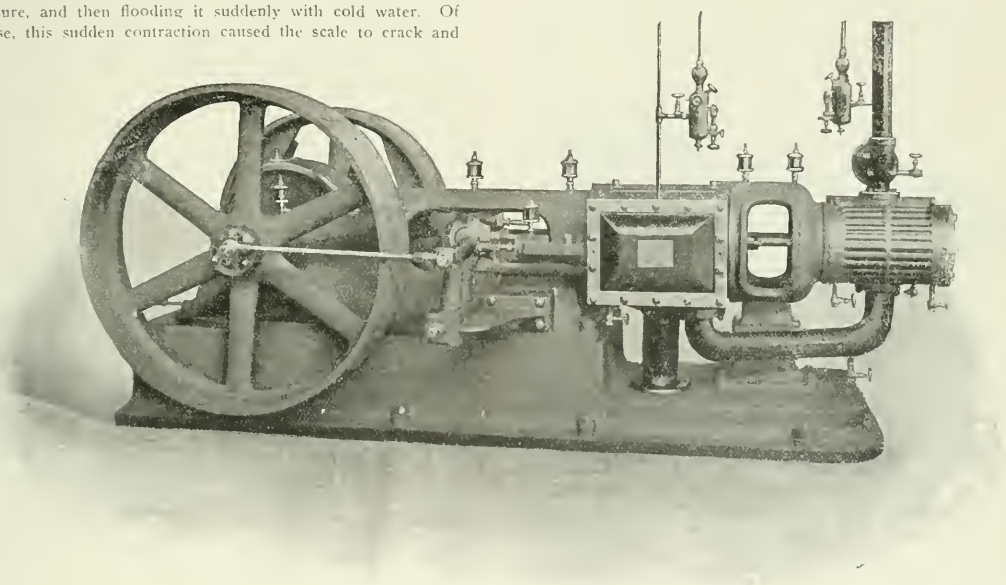
They are often very tricky manipulators, able to give an apparent exhibition of the wonderful disincrusting power of their purges. I caught one at one time cracking the scale out of a boiler by blowing it empty of its water, under steam pressure, and then flooding it suddenly with cold water. Of course, this sudden contraction caused the scale to crack and fall off, but a boiler maker had a nice little job afterwards in making the boiler tight. In another case I found that one of these manipulators had about ruined a boiler by first giving it a dose of muriatic acid before introducing his "compound." These are but two examples of the many tricks resorted to.

The best advice I can offer on this subject is: Never use any boiler compound, fluid, powder or whatever else it may be called, unless you know positively just what it is composed of and how it will affect the impurities in your boiler water and the boiler itself. Many of these quacks pretend to have made a chemical analysis of the water to be treated. This is frequently a mere farce, as the same old compound is trotted out on all occasions. Some submit to their proposed victim what purports to be an analysis, of their feed water. Many a time a subsequent bon-fide analysis, made by competent chemists, has proved to me the absolute worthlessness of these first supposed analyses. In the treatment of boiler waters always start with a careful analysis of the water, made by a competent chemist experienced in this line of work. Next, let an expert in this line of known reputation, and one who is not in any way interested in any method of treatment, suggest the best method of treatment; or should you think of using any "compound," fluid or powder that has been offered for treatment of your boiler water, let this chemist analyze it. If you are dealing with straightforward people, they will tell you the exact composition of their material, which the chemist can verify easily, after which the chemist or expert is prepared to advise you properly.

† See "The Locomotive," Vol. V, page 59 and Vol. XV, page 90.

THE M'EWEN AUTOMATIC ENGINE.

The first McEwen automatic engine was placed on the market in the spring of 1891, and during the eight years which have passed since then, hundreds of these engines have been manufactured and put in operation. They can now be found in operation in all parts of the United States and throughout the Dominion of Canada and for almost every conceivable kind of service. Its makers claim that no engine ever placed on the market has been more uniformly successful in operation, or has better withstood the test of time. While the design of this engine is practically the same to-day as when it was first placed on the market, improvements have been made on the minor details which have kept it fully abreast of the times. Originally designed particularly for simplicity and strength these very important qualities have been carefully kept in view in making later improvements. The character of the workmanship has been steadily improved, and the McEwen engine, as built by the Waterous Engine Works Co., at the present time, is as carefully and thoroughly constructed as any first-class, high-speed engine built anywhere in America. The engine is claimed to have fewer parts than any other engine of this type built anywhere in the world, and for qualities of strength, durability, economy and smoothness of running, it is unexcelled. On the one point of regulation the McEwen engine from the start established a standard, which, in spite of the many imitations by competitors, is said to never have been reached by any other engine in the world. All parts of these engines are made interchangeable, every piece being made to gauge, so that, if for any reason any part needs renewing, it can be supplied from stock, with the assurance that it will fit. All bearing surfaces are unusually large, and are carefully scraped and fitted to surface plates. Every piece is required to pass through the inspector's hands after every operation before passing to the next workman. Under this system it rarely happens that any defective work reaches the testing block, and here, as during the progress of the work, the inspection is rigid. Every engine is carefully and systematically tested before shipment, under conditions as nearly as possible approaching its future working conditions. The valves are set and carefully adjusted by means



The M'Ewen Automatic Engine

of the indicator and the regulation by means of an accurate tachometer. The bearings are all carefully adjusted and the engines operated for at least a whole day under loads varying from zero to one hundred per cent. overload.

The McEwen engine is a high-speed engine designed especially for extremely close governing under the severest and most rapid fluctuations of load—such as are met with in the driving of electric generators for electric lighting, electric railway service, mine haulage, electric crane work, etc. The accompanying illustration shows a compound McEwen engine, built by the Waterous Engine Works Co., Brantford, Ont.

ROLLER AND BALL BEARINGS.*

BY J. B. DETWILER, BRANTFORD, ONT.

The subject is a very extensive one and is the cause of a great deal of correspondence in our leading mechanical and scientific journals. No department of mechanical design or construction has received more careful consideration than that of roller and ball bearings. Very rapid strides have been made recently in the perfecting of roller bearings, making their employment more common. We read of roller bearings having been used 25 years ago, but with little success, owing chiefly to the way they were constructed, and it is only within the last few years that they have been so constructed as to make them practicable. For many years the only successful application of rolling motion to bearings was the ball bearing so universally adopted in bicycles, and although these bearings have been found most satisfactory when subjected to light loads, all attempts to apply them to heavy loads have so far resulted in failure, arising chiefly from the balls indenting the races upon which they run. As soon as this takes place, the balls begin to lose their friction reducing properties. If a semi-circular trough be constructed which accurately fits a ball and one end of the trough be raised, it will be found that the ball will move by sliding and not by rolling; this is indentation carried to the extreme. Another defect in the ball bearing is that the balls are allowed to touch each other, and as the touching point of any two balls are revolving in opposite directions, there must be a certain amount of friction. The same error in the construction of roller bearings was made until cages were introduced. These cages serve the double purpose of keeping the rolls in alignment with the axis of the shaft and of keeping them separated from each other, doing away with the friction caused by the touching points of the rolls running in the opposite directions as is the case of ball bearings. Judging from the various size of balls used in bearings, one might be led to suppose that ball bearings knew no law.

A few years ago very small balls were used, but they proved very unsatisfactory, for cones and cups were soon destroyed and had to be renewed. The same error was made in roller bearings, and when the cages were introduced, and less rolls used in the same size bearing, larger rolls had to be used to bear the same load. Those who advocate the use of small balls, and the same argument holds good with rolls, argue that as the balls bear on a point, and as more small balls can be placed in a bearing of a given size than large ones, there are more points of contact, and the result, a more durable bearing. The error in this argument is, in assuming that a ball or a roller bears on a point, which is not the case, excepting when working under a very light load, but when the bearing is loaded, the rollers or balls are slightly compressed and the very slightest compression causes the point of contact to enlarge. If a large roller or ball is compressed, to the same extent, the point of contact will be greater than in the case of the small roller or ball, because the larger the sphere the flatter the curve. Tests have been made to prove beyond doubt that the carrying capacity of rollers and balls is as the squares of their diameters, in other words one ½ inch ball or roller will carry as heavy a load as four ¼ inch ones. The writer has made tests with loading ¼-inch rollers in bearings until the weight was sufficient to elongate the rolls by rolling them out, and thus reducing the size, and in a very short time rendering the bearing useless.

The question is very often asked, how much do roller bearings reduce friction or how much less power does it require to run a shaft fitted with roller bearings than one fitted with ordinary bearings. While there is very little reliable information on this point, experiments have shown that friction increased little if any, with the increase of pressure, and that the friction increased considerably less than the proportion of the square root of the speed. In tests made by Geo. F. Symons it was shown with bearings 2½-inch in diameter that the friction developed was from .0025 to .005; these figures were obtained under comparatively light loads. In comparing ball bearings with babbitt bearings, it was found that under 200 lbs. pressure to the square inch, and 800 revolutions per minute, babbitt bearings 2½-inch in diameter lubricated with 20 drops of oil per minute, and having a ½-inch lateral play, heated badly. Under the same pressure ball bearings were running at 2,600 revolutions per minute, or more than three times as fast, without signs of heating. The American Machinist of October 17th, 1895, gives the following: "The first was in the shop of Brown & Sharp, where a set of rolls used for rolling sheet steel, cold, were first operated for some time with ordinary bearings, previous to the change, a 6-inch belt running over a 24-inch pulley on a machine had been found inadequate to drive it, and a 4-inch belt had been placed over it. The two belts arranged in this way had driven the machine, but it had been found impossible to run more than a few hours at a time on account of the heated bearings. After putting in the roller bearings it was found that a 1-inch belt would drive the machine when doing the same work, and we recently saw a 2-inch belt driving the machine, and were informed that it was regularly used, running on the same pulley. It had been found unnecessary to stop on account of hot bearings, and the speed had been increased 25 per cent." There is here shown such an enormous advantage in the use of rollers, as to make the plain statement of the facts seem like a fairy tale, but we can vouch for its accuracy in every particular. It shows that a very great advantage may be gained by roller bearings in some cases, and also shows that a very large proportion of the total driving power applied to rolls when used on such work is consumed in overcoming frictional resistance in the machine. The pressure required to slightly reduce the thickness of a strip of hard tool steel 6 in. or 8 in. wide is, of course, very great, and the actual foot pounds of energy required to do it, must be small. The consequence is that the great pressure upon the bearing causes corresponding frictional resistance in them which consumes practically about all the power applied to the machine, and this gives to the roller bearings a chance to make perhaps the very best possible showing. In a machine where the actual work to be done required more power, and the frictional resistance less, proportionately, the showing might be expected to be very different. Such a case, and one more nearly representing the average condition under which comparisons will be made, is to be seen at the establishment of the Gilbert Clock Co., at Winstead, Conn., where there are 600 feet of line shafting, having 104 bearings of the usual type, lined with babbitt metal, and these bearings were replaced by roller bearings. The shafting is driven by a 40 h.p. water wheel and, according to the brake or dynamometer tests made 25.02 h.p. of this was absorbed by the frictional resistance of the line shaft when using the old bearings as against 18 h.p. with the roller bearings, thus saving 7.02 h.p. or 17.55 per cent. of the whole power developed by the wheel, and 28 per cent. of the original friction of the shaft. Fourteen Mossburg roller bearings were on June 29th, 1897, applied to a 3-inch shaft, 80 feet long, running 200 revolutions per minute, and subjected to careful and repeated tests which showed a saving of more than 50 per cent. in power required to overcome the friction of the shaft running in babbited bearings. The shaft had been thoroughly tested when running in the ordinary babbited boxes, and found to consume by friction, when running at full speed, 0.21 h.p., and to come to a standstill in two minutes after being disconnected from the source of power. Similar tests were made after the shaft had been fitted with roller bearings; the power required to overcome the friction being found to be only 3.01 h.p. and the shaft revolved ten minutes after being disconnected from the source of power. The bearings have been in use six months, running 22 hours every day, and are in first class condition, showing little wear, and giving very little trouble. From an article taken from The Canadian Engineer, on roller bearings, by W. Bayley Marshall, C.E., we learn the result of the following test. A passenger train of six carriages fitted with roller bearings throughout, has been running for

*A paper read before the Mechanical Superintendents' Association.

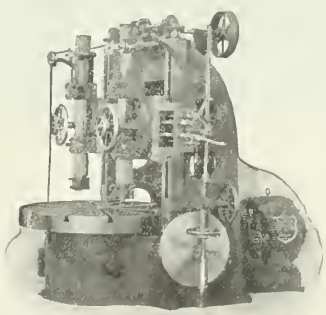
two years between Brighton and Kemptown with a total mileage of 70,000, and has shown a saving of from 12½ to 15 per cent. in the consumption of fuel, which saving has been obtained under most disadvantageous circumstances, inasmuch as the engine has to be kept in steam for about 16 hours per diem, whilst its actual running time is under seven hours. The tramway car, fitted with ordinary bearings, and weighing 2 ton, 15 cwt., was let loose from a point 56 feet up an incline with 1 foot 6¼-inch rise; it ran down this incline, and 57 feet on the level line at foot of same, or a total distance of 113 feet, the force expended was therefore 6,160 pounds, falling through 1.521 feet or 9,364 ft. lbs., the average frictional resistance was 9.364 divided by 113, or nearly 83 pounds, equal to 30.5 pounds per ton. A similar car fitted with roller bearings being let loose from the same point ran the full length of the level line available, namely 320 feet, and had not then quite come to rest. The total distance traversed being 376 feet. The force expended was about 9,364 feet pounds, average frictional resistance was 9.364 divided by 376, equals 24.9 pounds, or about 9 pounds per ton of load, a saving of 72 per cent. Relative starting effort of a tram-car on a gradient of 1 in 20; ordinary bearings, 100; roller bearings, 77; saving 23 per cent. on a gradient of 1 in 80; ordinary bearings, 100; roller bearings, 50; saving 50 per cent. on a gradient of 1 in 140; ordinary bearings, 100; roller bearings, 39.6; saving 60.4; results which require no comment.

Perhaps one of the most interesting among the general application of these bearings is that of the big bell at St. Paul's Cathedral, London, Great Paul, which with its head stock and other moving parts weighs nearly 25 tons, and which gave considerable trouble when mounted on ordinary bearings. The following results are instructive. When mounted on ordinary bearings the bell came to rest after the swinging effort had been discontinued, within one minute, when on roller bearings 6 minutes 55 seconds, showing that the frictional resistance of the latter was only about 1-7 of the former; a result remarkably in accordance with the starting effort tests given under the head of tramways.

With reference to the question of heating, it is an interesting fact that there has not been a single case of a hot bearing in all the experience so far gained with roller bearings. Although it is somewhat early to predict what the cost of maintaining these bearings will be, the results so far show that if they are constructed of suitable material, it will be extremely low. It has been found that polished and pressed steel or cold rolled steel is the best material for the rollers, and the boxings lined with steel have been proven by the writer to be far superior to cast-iron boxings. In all cases, if at all convenient, the boxings should be of the oscillating type to ensure perfect alignment.

SLOW SPEED MOTORS DIRECT CONNECTED TO MACHINE TOOLS.

One of the most important applications of electricity now-a-days is its employment to distribute power from the prime mover to the various machines to be operated. In this way a

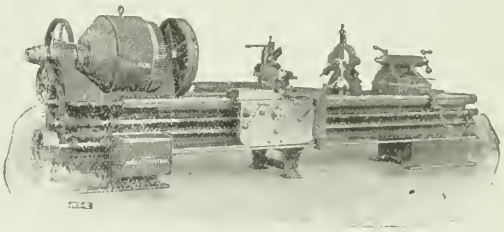


Motor Direct Connected to Boring Mill.

plant can be enlarged at small expense by the addition from time to time of motors as the machines required to be driven are installed. There are now many factories in this country which are equipped with slow speed motors directly attached to the driving shaft of all sizes and types of tools, the motors being part of the tools themselves. These motors do not at all interfere with the operations of the cranes now found in every well appointed factory by preventing them from dropping the piece into the tool itself. Great advantage is claimed to exist in cases in which electric driving by direct connected motors are used on machines required to be driven intermittently.

Among the advantages of direct connected motors is that of cost, as the price of a motor depends as much on its speed as on its horse-power. For instance, there is quite a difference in the price of two motors of equal horse-power, one geared to the tool and running at say one thousand R.P.M., and the other mounted directly on the driving shaft of that tool and therefore running at the same speed, which may be as low as one hundred R.P.M. In the case of the geared motor its speed is too high to attach directly to the tool, and hence reducing gears have to be used, which is a somewhat uneconomical and noisy method of driving, besides requiring more floor space for the motor. The makers of slow speed motors urge that the cost of these gears or the speed-reducing devices must not be lost sight of in making the comparison.

Some of the advantages claimed to be obtained by the use of direct connected slow speed motors are: All expense for power ceases the instant the switch is opened and the motor stopped; the tool can be located anywhere irrespective of lines of shafting;



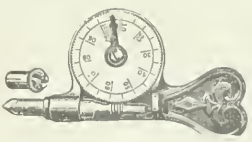
Motor Direct Connected to 26 in. Engine Lathe.

a much higher rate of output for the tool and machinist is possible; these motors occupy the space and take the place of the driving pulley on the tool; they are compact, protected from injury, moisture and dust; tools thus equipped can generally be run after the engine has shut down by connecting through a switch to the mains of a local central station; special tools equipped with direct connected motors may be moved readily to the piece they are to do the work on; the exact amount of power used by each tool can be accurately measured at any time by the use of instruments indicating electric current; the life and usefulness of a motor is greatly increased by running it at a slow speed; the use of electric transmission permits the generating units to be large, and to be concentrated near the boilers at that point most convenient for handling the supply of fuel.

The Jones & Moore Electric Co., Toronto, is Canadian agent for the Bullock type of slow speed motors.

SPEED INDICATORS.

Woodman's and Hudson's patent improved speed indicators, manufactured by the R. Woodman Manufacturing and Supply Co., 63 Oliver street, Boston, Mass., U. S. A., are now attracting a great deal of notice. The attention of dealers and others using and selling machinery is invited to the qualities which



combine to make this indicator, its makers claim, preferable to any other in use. It is adapted to pointed or hollow centers and has a raised sight on dial so as to count by touch, which is of great importance, especially in dark places, as it is only necessary to look at your watch and count the number of revolutions the dial makes, which, with the fractions, will be the exact speed

of the machine. It is accurate, reliable, of convenient size, neatly finished, and suited to carry in the pocket. The spindle is made of best tool steel.

THE CANADIAN ASBESTOS COMPANY.

The Canadian Engineer was the first technical journal to call attention to the advantages of "Asbestic" (asbestos) as a wall plaster and a fire-proof material for interior work in buildings, and it is satisfactory to know that time has fully justified the predictions made for it when introduced about four years ago. We learn from the Canadian Asbestos Co., of Montreal, who are sole manufacturers of this material, and whose principal warehouse is here illustrated, that 10,000 tons of asbestic were sold last year, and the output is increasing year by year. The original factory at Danville, Que., which was destroyed by fire the other day, is being rebuilt on a large scale and will be

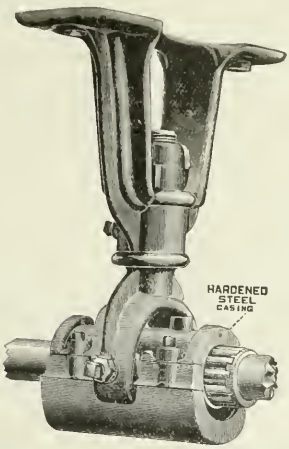
equipped with new machinery. The company now have 350 local agents throughout Canada, while asbestic plaster is used in the most modern structures now being erected in the United States and Great Britain. It has been called for in the reconstruction of the western block of the Government buildings at Ottawa, the hospital in that city, the Donalda College, Stanley Flats, Karn Hall, Her Majesty's theatre and many large private building in Montreal and other cities, while among the new buildings now under construction in Montreal in which it is being used are the publishing houses of La Presse, The Montreal Star, S. Greenshields, Son & Co.'s wholesale dry goods warehouse, Henry Morgan & Co.'s new wing, the St. Jean Baptiste church at Mile End, the municipal and school buildings of Westmount, etc. Among the shipments to distant points which the Canadian Asbestos Co. now have in hand are five car loads of asbestos and roofing paper to Dawson City, Yukon. The catalogue just issued by the company gives illustrations of some of the large structures in Great Britain, Europe and the United States for which asbestic has been adopted, while some remarkable tests are recorded showing the fire-proof, cold-proof, sound-proof and other qualities of asbestic. The same catalogue describes more or less in detail the other products of the company, such as asbestos cement for furnaces, retorts, stoves, etc., asbestos roofing and building papers, asbestos packings, lubricating compounds, mill board, asbestos cloth, fire-proof curtains, ropes, asbestine fire and waterproof paint, boiler coverings, and other engineers' and ship's supplies. The demand for goods of which asbestos is the raw material is so great that this company is about to open out another mine in the province of Quebec to which reference will be made in a later issue. As dealers in raw as well as manufactured asbestos the company supply the principal United States asbestos manufacturers. Our readers may remember a record shipment made by the company last autumn to one of these United States firms, the shipment consisting of 38,000 bags, or five train loads. This is the largest order for asbestos ever filled by any firm in the world. Wm. Sclater, whose jovial face is familiar to nearly every dealer in these lines of goods in Canada, and who may be called the pioneer in the trade, is president and managing director of the Canadian Asbestos Co.; B. Shepherd is vice president and B. Marcuse, who was one of the founders of the original asbestic factory at Danville, is secretary treasurer.

Ogdensburg, N.Y., capital is to put a large light draught boat on between that place and Montreal this season. Passengers and freight will be carried, and it is hoped the single boat will grow into a line.

BRANTFORD ADJUSTABLE DROP HANGER WITH PATENT ROLLER BEARINGS.



This illustration gives a good idea of the patent roller bearings, with outer steel casing, made by Goold, Shapley & Muir Co., Ltd., Brantford. Their advertisement in this issue will be of interest to manufacturers and others who wish to keep posted in mechanical ideas.

ACETYLENE FOR COOKING.

There has been a general impression that acetylene gas does not compare with coal gas or water gas for heating or cooking purposes, but it is the opinion of W. J. Stinson, of the Acetylene Manufacturing Co., of London, Ont., that this impression is because of the crude burners or stoves used in the experiments. In a letter to The Canadian Engineer Mr. Stinson supplies the following interesting information on this subject:

"I may say that I have been experimenting with acetylene, along the line of heating, during the past two years, and have acetylene gas stoves in operation with the most satisfactory results. We have not heretofore pushed this branch of our business to any extent, owing to the scarcity of carbide, but now that we may reasonably expect an abundant supply, we anticipate a very large demand for combination machines for both lighting and heating. The following tests as to cost are typical of a great many that we have made. We have tried to be as fair as possible, and to give no advantage to either acetylene or city gas. The results are what the general public is interested in, and we have tried to put these comparisons in practical form.

"An oven full of slow-baking fruit cakes, etc., was baked in a Detroit Jewel gas stove, in one hour and ten minutes, with a consumption of thirty-one (31) cubic feet of city gas, which at $1 per M. cost three and one-tenth (3 1-10) cents. An exact duplicate of this oven of cakes was baked in one of our regular acetylene ovens, such as we supply to our customers, in one hour and thirty minutes, with a consumption of three and one sixth (3 1-6) cubic feet of acetylene gas, costing two and one-half (2½) cents, with carbide at four (4) cents per pound. A given quantity of water was raised from freezing to boiling point, in five minutes by the consumption of two (2) cubic feet of city gas, costing one-fifth (1-5) of a cent. The same quantity of water was raised from freezing to boiling point, in four and one-half (4½) minutes, by the consumption of one-third (⅓) of one cubic foot of acetylene, costing one-fourth (¼) of one cent. We have made dozens of similar tests, all giving practically the same results. The above estimates have been made on the basis of carbide costing four (4) cents per pound, and city gas costing $1 per thousand feet. City gas is higher than this in most cities and calcium carbide will soon be very much lower than at present. You will notice that in baking acetylene has a very decided advantage, while in the water boiling test, city gas has the advantage. We can probably account for this difference by stating that we use, on our acetylene stoves, a somewhat better oven than is usually found in connection with gas stoves. It needs but a slight reduction in the price of carbide to place acetylene away ahead of coal, water or oil gas, as far as economy is concerned, but economy is not acetylene's only advantage. By its use the disagreeable smell found in connection with the ordinary gas stove is entirely done away with, as acetylene gives off no odor when being burned, either as a lighting or a heating flame. An ordinary gas stove is a more or less smoky, dirty, greasy affair, but an acetylene stove does not smoke, neither is it a grease or dirt producer. The general public admit the decided advantages of acetylene as an illuminant, and it is but a matter of a very short time until it will be looked upon as the ideal heat producer as well."

CANADIAN SOCIETY OF CIVIL ENGINEERS.

THE VISIT TO BOSTON.

The trip to Boston, which was planned as part of the programme of the 14th annual convention of the Canadian Society of Civil Engineers, will long be remembered by all who had the good fortune to take part in it. After the annual business meeting, reported in last issue, the excursionists gathered at Bonaventure station, where by the courtesy of the Grand Trunk Railway Co., and the Pullman Palace Car Co., a special train with three sleeping cars was in waiting to take them to the New England capital. The Central Vermont and Boston and Maine gave the society free running privileges over their lines, and the party arrived in Boston on Thursday morning, February 1st. They were met at the station and cordially welcomed by a deputation from the Boston Society of Civil Engineers, who escorted them to their headquarters at the Hotel Brunswick, where the formal welcome was made by the president of the Boston Society, C. Frank Allen, professor of railway engineering in the Massachusetts Institute of Technology. On behalf of the Canadian society, Prof. Bovey, president-elect, thanked the Boston society for their hospitable welcome.

The first event in the list of Boston excursions was a visit to the Massachusetts Institute of Technology, the visitors being piloted by Desmond Fitzgerald, its professor of civil engineering; Gaetano Lanza, professor of mechanical engineering; Geo. F. Swain, Hayward professor of civil engineering, and C. Frank Allen, professor of railroad engineering. This great institution has grown from small beginnings till it now has four large buildings in which are taught civil and mechanical engineering, mining engineering and metallurgy, architecture, chemistry, electrical engineering, biology, physics, chemical engineering, sanitary engineering, geology, naval architecture and general studies. The various engineering and technical departments are equipped with machinery and testing appliances, many of which are of the most modern description. This school gives the degree of B.Sc., and has 1,200 students. The institution has ten technical libraries, having an aggregate of 47,000 volumes; while it receives 850 technical and trade papers, the largest collection, it is believed, in the world.

In the afternoon the party visited the new south terminal station of the Boston and Albany, and New York, New Haven and Hartford railroads. The station buildings cover 13 acres, the main building being 850 feet long by 725 feet wide. The train shed is 602 feet by 570 feet, and has 28 tracks in the main floor. Beneath this and below tidewater is a subway for suburban service. The switches and signals are operated by the electro-pneumatic system. There is a 2,000 h.p. steam plant for generating electricity and operating the air compressors, ice-making and air-brake testing plants, and a plant for hot air and hot water heating. There is also a plant for making and compressing the gas used in the cars, the capacity being 120,000 cubic feet per day. The station cost $15,000,000, of which $6,000,000 was spent in buildings and plant. Geo. B. Francis, the resident engineer, and A. B. Corthell, the assistant engineer, acted as guides in this interesting visit.

The evening was pleasantly taken up with a lecture under the auspices of the Boston society, by Frederick P. Stearns, chief engineer of the Metropolitan waterworks, on the new waterworks system now under construction. The lecture was illustrated by stereopticon views, and was most instructive. The water supply of the metropolitan area of Boston is derived from a chain of ponds, basins and streams extending from a point about ten miles outside the city to a distance of 50 miles north

west, and running into the highlands around Nashua, where the latest new source of supply is the south branch of the Nashua river. The water sheds of these basins and streams have an area of 212 square miles, with a total daily supply in the driest known years of 384,000,000 gallons. Greater Boston, for which this supply is intended, has a population of 1,100,000, and some 28 cities and towns can be admitted to the benefits of this supply. To prepare for the acquisition of the latest extension to these works—the Nashua reservoir—6½ miles of railway had to be taken up, 360 houses, including six school houses and four churches, removed, with inhabitants numbering 1,711. The surface soil for this reservoir was stripped at a cost of $3,000,000, including the draining out of some swamps, and the new water basin formed will contain 63 billions of gallons, having a water surface area of 4,195 acres. In building the dykes for these reservoirs the ordinary surface soil was largely and successfully used as puddling material in combination with masonry dams. One feature about these reservoirs is that no attempt has been made to construct square or circular basins, but the conformation of the land is left as if nature, and not the hand of man, had planned the whole scheme. The effect is very picturesque, and this chain of lakes will soon be one of the most charming sights for the people of Boston. After Mr. Stearns' lecture the visitors were taken to the rooms of the Boston society, where they were regaled by ice cream, light refreshment and drinks, and were shown the society's valuable library.

On Friday morning the party were taken under the guidance of Alexis H. French and W. Warren Cummings, to the works of the New England Gas and Coke Co. at Everett, a suburb on the Mystic river. The superintendent, Louis J. Hirt, accompanied the party and explained very clearly the process of manufacture. As this is dealt with in an interesting article in another part of this issue by Charles Baillairge, one of the Canadian visitors, we need only add that all were pleased with the visit and enjoyed the luncheon prepared for them by the company at the close of the inspection of the works. After luncheon Mr. Heckman called the party to the front steps of the office, and took the photograph reproduced in the accompanying engraving.

31¼ and 48 inches; diameter of pump plungers, 37 inches; stroke of pistons and plungers, 60 inches; revolutions per minute, 30; horse-power, 4co; contract price, $45,500 each, exclusive of foundations. Steam will be furnished by three vertical fire tube boilers. Each boiler will be 8 feet in diameter, 25 feet high and will contain 378 2-inch tubes. Thickness of shell, 25-32 of an inch. Heating surface 2,146 square feet.

The next point visited was the Natatorium, at Brookline, which is considered one of the best examples of municipal bath houses in the United States. Messrs French, Bryant, Forbes and Fletcher showed the visitors through this admirable institution, which we hope to be able to describe somewhat in detail in another number. The evening was devoted to the annual dinner, of which a report was given in last issue.

On Saturday morning the first event on the programme was a visit to the State Board of Health experimental station and filtering plant at Lawrence, but owing to the early hour at which the train started only one member was on hand. He had a car to himself on the journey, and was honored by a deputation and several cabs on arrival at Lawrence station. We hope to be able to give an account of his trip in next issue.

The members who remained in the city paid a visit to the Boston library, of which every citizen is justly proud. This great institution has its own steam and electric lighting and power plant, its own bindery and printing office, from which its catalogues, bulletins and special lists of books are issued. This library grew out of a gift of $100,000 made about 50 years ago by Joshua Bates, an Englishman, of London, who had lived some years in Boston; now the institution has in its main building 530,000 volumes, and the ten branch libraries have a total of 170,000 volumes besides, while 17 other stations are used to facilitate the distribution of books to the citizens.

During this day parties of the visitors made excursions on their own account, which included visits to the Boston Electric Light Co.'s central power house at South Boston, the Boston Elevated Railway Co.'s power house in Albany street; the freigfit sheds of the Boston-Maine system, Brockton Sewage Works, etc.

One of the most interesting and enjoyable of the many excursions was that to Harvard University, where President

Canadian Society of Civil Engineers.
From a Photo by I. W. Heckman, C.E., taken at the office of the New England Gas and Coke Co., at Everett, Boston.

In the afternoon the visitors were taken to the Chestnut Hill reservoir and new pumping station, where Charles W Sherman and W. J Sando acted as guides. There are four engines, representing different types and designs, the latest of which is a slow running engine of large capacity, designed to pump 30,000,000 gallons per day A new low service station is now being completed and will contain three vertical engines of 35,000,000 gallons capacity per day each The dimensions of these pumps are as follows: Diameters of steam cylinders, 17.

Eliot and several of the professors accompanied the Canadians around these historic buildings. They were shown how the students lived, and were treated to one of the every day students' lunches in the classical Memorial Hall. After lunch President Eliot gave the visitors an interesting sketch of the history of Harvard, and then showed them the remarkable collection of glass flowers—unique of its kind—of which we should like to speak at another time. Very instructive, too, was the visit to the observatory where Profs. Pickering and Bailey, so well

known in the astronomical world, showed the visitors some of the 10,000 photographic negatives of the heavens, which are stored up as books of the stars.

To the several professors of Harvard and the Massachusetts Institute of Technology, and to Leonard Metcalf, secretary of the Excursion Committee; to S. E. Tinkham, secretary of the Boston Society, and to Howard T. Barnes, Edmund S. Davis, H. Bissell (chief engineer of the Boston and Maine), H. A. Carson, of the Boston Transit Commission, and many others the visiting members of the Canadian society are under a heavy debt of gratitude for the trouble and time they took in showing them the engineering sights of Boston, and the visit will long remain one of their most pleasing memories. On returning to Montreal hearty votes of thanks were passed to the Grand Trunk and the other railways to whose kindness they were indebted for the transportation to Boston and return. The details of the trip were as usual admirably managed by the secretary, Prof. C. H. McLeod, who never spared himself when the comfort of the members was in question. The society is indebted to Mr. McNab, of the engineering department of the G.T.R., for the suggestion of this trip, which proved to be the most instructive as well as the pleasantest of all the society's excursions.

Regular Meeting, March 15th.

At the meeting of the Canadian Society of Civil Engineers, held on March 15th, the lecture on the Transmission of Electrical Power, by Prof. Owens, announced for the evening, was not delivered, owing to the absence of the lecturer, who was unavoidably detained in Quebec. In place of the lecture a short paper by Mr. H. J. W. Finch, Stud. Can. Soc. C.E., on the Canadian Pacific Railway Transfer Slip, Vancouver Harbor, British Columbia, was read. This slip is one used in connection with the transfer of coal from Vancouver Island to the mainland, and is situated near the C.P.R. wharf at Vancouver. The cars, twelve at a time, are carried on barges. The transfer slip is a pile structure. Connection is made between the fixed flooring of the slip and the barge by means of a counterbalanced apron, 33 feet long by 30 feet wide.

CANADIAN MINING INSTITUTE.

The annual general meeting of the Canadian Mining Institute was held at the Windsor Hotel, Montreal, on the 7th, 8th and 9th of March, the following members being in attendance: B. T. A. Bell, Ottawa; W. Johnstone, Crow's Nest Coal Co., Fernie, B.C.; R. Jeffrey, Toronto; C. Fergie, Intercolonial Coal Co., Westville, N.S.; Geo. McDougall, Montreal; A. H. Stevenson, Montreal; J. Stevenson Brown, Montreal; R. Meredith, Montreal; H. W. de Courtenay, Montreal; Geo. E. Drummond, Montreal; Eugene Coste, Toronto; J. W. Evans, Sudbury; A. C. M. Hay, Rat Portage; C. Morgan, Toronto; H. Wylde, Halifax; N. M. Campbell, Montreal; David G. Kerr, Marmora, Ont.; P. Kirkgeear, Deloro, Ont.; Prof. W. G. Millar, School of Mining, Kingston, Ont.; Dr. W. L. Goodwin, director School of Mining, Kingston; W. Blakemore, Montreal; Archibald Blue, director Bureau of Mines, Toronto; A. Boas, Montreal; R. S. Hopper, Montreal; R. Blackburn, Ottawa; Major-General Sir Henry C. Wilkinson, Regina, N.W.T., and London, Eng.; S. Simpson; Dr. J. B. Porter, F. W. Maclennan, W. H. Ogilvie, S. F. Kirkpatrick and A. R. Archer, McGill University, Montreal; T. Denis, A. P. Low and A. E. Barlow, Geological Survey, Ottawa; Dr. Frank W. Adams, McGill University, Montreal; R. W. Brock, Geological Survey, Ottawa; Prof. A. Courtenay De Kalb, Kingston; C. C. Hanson, Montreal; J. B. Smith, Montreal; J. B. Tyrell, Dawson City; J. Obalski, Quebec; A. W. Fraser, Ottawa; Chas. Brent, Rat Portage; J. F. Higginson, Buckingham, Que.; J. D. Craig, Kingston; S. N. Scott, Kingston; J. D. Maclennan, Kingston; E. L. Fralick, Kingston; F. G. Stevens, Kingston; F. Gilbert, Kingston; F. H. Hopkins, Kingston; Thomas Bacon, Kingston; S. S. Fowler, London and British Columbia Gold Fields, Nelson; Major R. G. Leckie, Sudbury; John Blue, Eustis Mining Co., Capelton, Que.; Jas. Reed, Reedsdale, Que.; F. T. Peacock, Montreal; D. Brainerd, Montreal; R. G. McConnell, Geological Survey, Ottawa; F. Cirkel, Ottawa, and J. M. Clark, Toronto.

Wednesday morning.—In the absence of the president, John E. Hardman, the chair was taken by Geo. E. Drummond, who, in a short opening address, stated that since last year many things had happened of great interest to the mining community; and that, though two or three occurrences had taken place in the mining world which were liable to discredit Canada in the eyes of investors, yet, as a whole, the mineral development of the country had been satisfactory.

Secretary Bell moved that the minutes of last year's meeting be accepted as read, they having been printed and in the members' hands already. He gave the names of twenty-three gentlemen who were proposed as new members of the institute. These were unanimously elected. The financial statement, he said, showed up very well, and proved that the growth of the Institute, both in numbers and in influence, was highly satisfactory. Several members of the Institute, he said, were now helping the cause of Great Britain in South Africa; and the previous day he had received from Thos. Brown, a letter, dated Cape Verde Islands, regretting his inability to read a paper before the Institute this year, but expressing the hope of being able to do so for the next meeting, on the subject of "The Effects of Lyddite." Since last meeting, five members of the Institute had died, viz., J. McGregor, W. G. Nelson, Morris Buck, J. T. Tuck and A. H. Budden. The papers read at the previous year's meeting had been published and met with a cordial reception, having been republished in several American and European technical journals. He stated that he had had several interviews with the Minister of Customs, and had succeeded in obtaining an Order-in-Council placing gold dredging appliances on the free list. The Quebec Legislature also had passed an Act exempting mining property from municipal taxation for a further period of ten years. He then gave a brief resumé of the mineral development of Canada during the past year. It was very hard to give a just idea of the output, owing to the fact that the Provincial and Dominion Governments all had different standards, and their fiscal years ended at different periods. It would be a good idea to suggest that there should be some uniformity in these matters. Every mining man would agree with the statement that in Nova Scotia the returns of mining matters were arranged in a disgraceful manner. Fifteen million dollars, he thought, would be a conservative estimate of the amount of gold produced in the Yukon last year. In British Columbia, according to W. F. Robertson, the metallurgist, there had been a very material advance, though on certain lines, no doubt, it had been unsatisfactory. On the whole, however, there had been healthy, legitimate progress. Ontario's minerals showed an increase of 17 per cent. over previous year. The nickel industry showed signs of rapid progress, and will probably before long become a great one. Of Quebec, about the same might be said, and mica was showing up well. Electro-metallurgy, was responsible for considerable progress at Buckingham, as it was by that process that phosphorus was being obtained direct from the apatite, with ferro-manganese for a by-product. Mica had been found to be the best substance for annealing steel, also for boiler coverings. In Nova Scotia, the conditions were encouraging, and the coal output had largely increased, owing to the finding of larger markets. The Dominion Coal Co. at Sydney would make a great showing after a while. In gold there had been a slight falling-off. Many of the mines had been bonded and were being he'd by the owners without working. The following would be a rough but conservative estimate of the net value of the Dominion's mineral production for the past year: Northwest, $18,000,000; British Columbia, $11,000,000 to $12,000,000; Ontario, $8,500,000; Quebec, $3,000,000; Nova Scotia, $8,000,000; or, roughly, a total of about $48,000,000.

Dr. Goodwin, in seconding the adoption of the secretary's report, said it showed many encouraging signs. Not only did old industries hold their own, but several minor industries were beginning to come into play.

It was resolved that the Institute should, as a body, contribute $250 towards the Canadian Patriotic Fund, and that in addition a subscription should be opened at the meeting to receive individual subscriptions. In moving this resolution, the secretary announced that $100 had been already received from the Canadian Copper Co., and $100 from the Acadia Coal Co., for patriotic purposes.

W. Blakemore remarked, in connection with this subject, that no body of men were more dependent upon the protection of the British flag than mining men, and it was fitting that they

should show their feeling in this matter. Archibald Blue said that not only had the Canadian boys in South Africa shed an honorable lustre over the whole Dominion, but that the war would help this country in a material way as well. In future, not merely would the money requisite for the development of Canada be more easily obtainable, but interest in us had been so quickened that emigration would look this way also. One of the lessons of the present war to the people of Great Britain would be the value of sending their men to the colonies. Had a larger proportion of the families who had left the Mother Country to settle in the United States and foreign countries gone instead to South Africa, Canada and Australia, there would probably be no South African question to disturb the world's peace to-day. The British connection was a great thing for the Dominion, and more especially for mining men, whose duties often took them to undeveloped countries. It was unanimously resolved to remit the dues of those members who were upholding the honor of the flag in South Africa.

Secretary Bell said that the Institute was now in a position to say who should, and who should not be members. He had no wish to make it a close corporation; but he certainly thought it ought to be a purely technical or business society, so that when a man should be able to say he was a member of the Canadian Mining Institute, it would mean something, and prove that he had the right, by experience and education, to really call himself a mining engineer. He thought that members of the Institute should be persons engaged in the direction and operation of collieries, metal mines, blast furnaces and metallurgical works, mining, mechanical, electrical or civil engineers; geologists, metallurgists or chemists; and such other persons who from their connection with the profession of mining the council might see fit to elect. And that Associate members should be persons not eligible in the foregoing, but such as the council should deem worthy of admission; and that they should enjoy full privileges of membership. This brought up the question of "amendments to by-laws and constitution," and a committee was appointed to enquire into and decide upon the matter.

Wednesday Afternoon.—A. P. Low read a paper on the Iron Ores of Hudson's Bay, in which he told the history of his explorations in that district. The first mention of Labrador ores had been made by Dr. G. R. Bell in 1877. With every extensive exploration, he said, large new areas of valuable iron ores had been discovered, and with further efforts no doubt other areas would be found, some of which might prove sufficiently accessible to become of great commercial value. At present, the lack of railroad facilities rendered the ores of Ungava Bay and the interior useless. The coast deposits could perhaps be shipped down on lighters, but the season for navigation was probably not more than three months and a half. Another question was that of fuel. No coal had been found in that country. There was a large mass of driftwood on the islands near the coast of the bay, but he did not know whether this would answer for smelting purposes; and wood for making charcoal would need to be transported a great distance. There was plenty of water power for electric smelting. The chances were, however, that these deposits would remain one of the undeveloped resources of the country for a long period.

Archibald Blue said he had been on Lake Temiscuing, and found that there was a streak of jasper running across under it, with iron in close connection. On Lake Boya a very interesting discovery had been made, the diamond drill having shown that hematite extended below the bed of the lake for 188 feet, which would represent an enormous amount—some 12,000,000 tons. Deposits of lead hematite had been found to extend several miles from there. There was a probability that the jasper region extended all the way from Lake Superior to Lake Temiscuing, and this region ought certainly to be explored. He would like to know more about the transportation question, in connection with the ore areas of which Mr. Low had spoken.

A. P. Low replied that if a railway were run from Ottawa, in continuation from the Gatineau Valley Railway, the haulage of the ore would be about 400 or 500 miles by railroad from the southern end of James' Bay, to which the ore could be brought down on lighters during the summer.

Secretary Bell asked what sort of navigation was there on the bay? Mr. Low replied that there was deep water right up to the shore. Hudson Bay was open to ordinary navigation from the middle of June up to November, but Hudson Strait would not be open probably before the middle of July.

The next paper read was one by R. E. Chambers, of New Glasgow, N.S., on the Iron Deposits of Bell Island, Conception Bay, Newfoundland, in which the writer stated his opinion that perhaps one could hardly adjudge at their true value the Newfoundland deposits. For high grade quality and economical working they were remarkable.

Chas. Fergie, Westville, N.S., then gave some results in the use of a rotary pump as against that of the straight line type.

Arch. Blue read a paper entitled, Are there Diamonds in Ontario? Briefly touching on the manner in which it had gradually dawned upon Canadians that Ontario was a great mineral country, the writer stated that nickel, copper, gold, iron, graphite and mica might be said to occur abundantly. One highly important mineral, it was true, Ontario did not possess to any extent, and that was coal; was it impossible, however, that fuller exploration would eventually prove that Ontario possessed carbon in its purest or gem form, viz., the diamond? Corundum was there in quantity; and where this existed, there was always a hope that sapphires and rubies existed also. Small sized diamonds had been found in the States of Wisconsin, Ohio and Michigan, and these had been imbedded in the glacial drift. Now the materials of this drift had come down during the Ice Age; and in Ontario, many stones and gravels had been discovered identical in composition and structure with those in the drift in which these diamonds had been found imbedded. From the geological formation of the Keewatin district, he thought that it was there that diamonds should be looked for, and with considerable prospect of the search being rewarded with success.

Dr. Goodwin brought to the attention of the Institute the fact that recently some materials had been discovered of greater hardness even than diamonds. Mr. Barlow stated that Dr. Lawson had remarked, several years ago, that he had but little doubt that diamonds would eventually be found in the districts north of Lake Superior. A. P. Low remarked that the diamonds referred to in Mr. Blue's paper were supposed by some to come from the Hudson's Bay region, though he was at a loss to know from what part. They might possibly occur on the islands near the east coast, where there were Cambrian or Huronian rocks, capped with a considerable thickness of black shales, on the top of which there were several hundred feet of trappe. In St. James' Bay was a mass of gneiss rock, composed largely of garnet, with hornblende also in the composition; and this somewhat resembled the sort of rock found at Kimberley, where the diamonds came from. Eugene Coste said that probably the diamond was a constituent of the plutonic rocks, just as magnetite was; and he did not think that in looking for diamonds it was necessary to confine one's attention to carbonaceous shales. A much better place to search was where the plutonic rocks were driven upwards, and denuded, and showed their inner parts, like the neck of the Kimberley mines.

Wednesday Evening.—The proceedings opened with a short paper by C. E. Morgan on Mining Pumps. C. Fergie remarked that there was not a single pump in the market really made to work with compressed air, though in 50 or 75 per cent. of the mines air was the motive power used. R. W. Brock, of Ottawa, read a paper on West Kootenay Ore Bodies. J. Burley Smith, referring to the writer's mention of the limitations of prospectors, said that the duty of a prospector generally was to look for surface indications; the work of tracing the vein was properly the duty of the mining engineer. A. W. Stevenson said he had no particular wish to criticize, but judging from the manner in which some mining properties were being developed, it would be just as well to take the whole mountain, and, starting from the top and going downwards, to mill the whole thing. And perhaps it would not prove so much more expensive than the operations in current use, either. W. Blakemore referred to the vast amounts expended in developing properties which were absolutely worthless, the idea being perhaps to show a little work, and then sell out at a profit. In many cases it would have cost no more money to really develop the properties in question, than had been already used merely in putting them in shape for selling. If it had been spent in an honest attempt to do the best possible for the property, the money would not have been wasted, and at the same time there would be much more encouragement for investors of capital in this country.

W. G. Millar, of Kingston, gave an address on Corundum, which, said he, existed throughout a large area in Ontario, the quality of which could not be excelled. The uses of this mineral

were constantly being extended. Some forms of metal, it had been found, were not readily acted on by emery alone, and now manufacturers were beginning to mix corundum with their emery, in order to improve the latter's abrasive qualities. It had also been found to be better than emery for sharpening circular saws, as it did not spoil their temper. Perhaps also other uses would be found for it in pulp mills. It had been at first thought that its place would be taken by carborundum; but experience had shown that the latter in some respects was by no means equal. It had been stated by some that in North Carolina there were such enormous quantities of corundum that the prices would be reduced; but on going down to that state and investigating, he had found that the quality was inferior. The corundum of Ontario could be extracted from the rock easily; in North Carolina, however, much of it had to be treated with acid, which was a very costly process.

Archibald Blue stated that a company had been formed to develop the corundum industry in Renfrew and Hastings counties, at first with a capital of $250,000, which afterwards they had decided to increase to $1,500,000. Steps were now being taken to put up a big plant, and it was expected to place the article soon on the market. Much correspondence had been received from Great Britain, United States and Europe, so it looked as though there would be a large market awaiting it, so soon as it could be produced in quantities. One other possible use for corundum not mentioned, he said, by Mr. Millar, was as an alloy for aluminum. He did not know whether any satisfactory process had yet been discovered to this end; but he felt sanguine that some persevering man would ere long succeed in finding a way to use it in the production of aluminum. Should this be done, it would add immensely to the value of the ore in this country. Prof. Dick Callum remarked that the only difficulty in the way of this consisted in making it sufficiently fine to combine. Dr. Adams said the rock is which corundum occurs varied greatly in color—from light to dark. In the places where it occurred at all, it was usually very abundant, and he had no doubt but that it would prove a highly profitable industry, provided the prices keep up satisfactorily.

Thursday Afternoon.—The next session of the Institute took place on Thursday afternoon, many members having expressed the wish to seize the opportunity of being in Montreal to attend to private business in the morning.

J. M. Clark read a paper on the Mining Laws of Ontario in which he gave a short history of the mining laws of that province and a synopsis of their present condition. It was very desirable, he thought, that the whole question of company law should be simplified and put into a more satisfactory condition. It was a matter for congratulation that the mining laws in Ontario were largely statutory, the power to interfere with mining matters except by special parliamentary legislation being very restricted. Eugene Coste said, no doubt the mining laws of Ontario were by no means perfect, but, on the whole, they were fairly satisfactory. It was a matter for congratulation that in that province there was an attempt at having a system of mining laws, not very subject to Orders-in-Council. In this respect it was a great contrast to the way in which the Yukon country had been governed from Ottawa. In the Yukon, it could not be said that there was any mining law; it was governed by mining regulations, made in the Department of the Interior, signed by the Minister, and changed every day or every week or so. The variability of these regulations had been the curse of that country, and Mr. Fawcett, the gold commissioner, had acknowledged he did not understand them himself.

Mr. Fraser said that in mining as in all other legislation so far as his experience went, the all-important point was that it should be clear and definite, and of as permanent a character as possible, without changes from year to year, if they could possibly be avoided. Many of the men engaged in mining operations—prospectors and others away out in distant regions—were not familiar with the changes that were taking place; they had neither the time nor the opportunity to study these changes, and for these reasons the legislation should be as definite and permanent as possible. He was glad to bear testimony to the just character of the Ontario mining laws. They were a credit to the province, and showed an evident desire on the part of its legislators to meet any difficulties that might arise regarding its mining interests.

J. C. Gwillim, of Ottawa, contributed some Notes on the Atlin Gold Fields. The Atlin region, like some other gold fields, he thought, had been over-rated, the placer district being confined to seven or eight creeks in a region about ten miles by twenty. Last spring, the population had reached perhaps 5,000, but now it could hardly exceed 1,500, many people having moved to Cape Nome and other fields. This country was more easily accessible, and the climate more favorable than in the region further north. Labor fetched about $5 per day, and provisions were about twice as expensive as in the outside world. The great drawback was the British Columbia system of mining laws, which limited the claims to a length of 100 feet, thus not giving room to deposit the debris and continue working. Many claims had been deserted when only half worked out. No doubt the future would show what could be done by hydraulic mining on a large scale.

Eugene Coste said the mining laws were a disgrace to the province, and went on to give some instances of the manner in which the British Columbia Government, in its desire to keep out aliens and foreign companies had really legislated against the development of the country even by Canadians.

Eugene Coste followed with a paper on the Natural Gas Fields of Ontario, in which, after giving a minute account of the operations of boring in several gas wells in that province, with an account of the various strata through which the drill passed in each instance, he went on to explain his theory of the formation of natural gas. He claimed that the gas-producing strata were not of organic origin, but the result of volcanic activity in past ages. Dr. Goodwin wondered whether there was any evidence of the formation of hydrocarbons in any stratum where organic origin was clearly altogether out of the question. Several facts, he thought, pointed to the chemical theory of the origin of hydrocarbons.

The report of the committee appointed to look into the proposed amendments to the by-laws and constitution was presented, from which it appeared that they had come to the conclusion that the whole subject was very much larger than had been anticipated. It was resolved to leave the matter over until the next annual meeting, and a committee, consisting of Archibald Blue, Dr. Goodwin, S. S. Fowler, Mr. Hay, J. Burley Smith, W. Blakemore, Mr. Hopper, Mr. Fraser and B. T. A. Bell, were appointed to thoroughly investigate the matter and report at that time.

It was ordered that the papers should be printed in the annual report. A notice of motion was presented to provide for the establishment of a reference library and headquarters for the Institute in some central locality (probably Ottawa), as provided for in the constitution.

Thursday Evening.—Dr. Porter, of McGill College, gave a very interesting lecture illustrated by views of mining operations, exterior and interior, in Canada, United States and Great Britain. A. P. Low also presented some fine views, taken while on his expedition to the Hudson's Bay country, showing forth the habits of the native Indians and Esquimaux.

R. G. McConnell, of Ottawa, read a paper on the Gravel Benches of the Klondike, which provoked a lengthy discussion. Eugene Coste stated that when he was in that country last September, the Government had not spent a cent in making roads from Dawson City to the Klondike. The cost of transporting goods was enormous—about one cent per pound per mile. It was a shameful thing, that the Government, which charged a royalty of 10 per cent. on the gross output of the mines of the Klondike should not have built one mile, or one inch, of road. To the men who went up in that frozen north country, it was cruelty; and Mr. Sifton and the Ottawa Government, he thought, ought to be brought before all the Cruelty Prevention Societies in the country for the way in which, for four years and more, they had allowed this to go on, and that after making money out of the country. For in a speech in Manitoba recently Mr. Sifton boasted that he had made the Yukon pay for itself, and had made $670,000 profit besides. In answer to a question from the chairman, he stated that there ought to be no great difficulty in building roads. The chief difficulty was to put the Government into a frame of mind to get started in earnest. Secretary Bell said that so long as a 10 per cent. royalty should be exacted by the Government British capitalists would refuse to invest money. For all practical purposes the Klondike was a dead issue. Mr. Ogilive, he went on to say, had stated that there was $50,000,000 in sight in the

Klondike. Now, Mr. Ogilvie was a good man in his own line, but no competent mining engineer would ever commit himself to such a statement as that. The cost of getting into the country was enormous. More money had been taken into the Klondike than had ever been taken out of it. J. B. Tyrrell agreed that the 10 per cent. royalty was too onerous, and a very serious drawback in the eyes of capitalists, who believed that the margin might be close. Besides the royalty, there were so many other percentages—the banks charged 3 per cent. for assay and 2 per cent for export drafts. Each man, also, had to pay for a miner's license, all of which was a handicap to the country. Then, again, the probability was that only honest men paid the royalty, the rogues finding a way out of it, thus creating a premium on dishonesty. The exemption of the first $5,000 only made it easier to do this. He trusted that the Government would take the matter up thoroughly, and put it on an altogether different and more satisfactory basis. According to reports of the United States Mint, the output of the Yukon during the past year was about $16,000,000, though royalty had only been paid upon $9,000,000 to the Canadian Government. A better system would be for the Government to establish an assaying office and buy the gold outright on the spot, giving certificates for the same, redeemable in cash when the owner should reach the outside world. If the Government charged, say, 3 per cent. upon the assay, all expenses would be more than met—and it was not desirable to make a large profit, so long as the country should be self-sustaining. Such a system would mean that all the gold produced would be recorded. At present, claims on the product of which the royalty had not been paid, were liable to forfeiture. This was a defect which would be removed if a record were kept of the entire output. This could easily be done, as all gold going out of the country had to go either up or down the river, and gold was too heavy to be carried on the person. With regard to the prospects of placer mining in the Yukon, he believed it would last for twenty years yet. Many times the amount which had been taken out remains yet to be found. He was speaking of known properties only—but in addition to those, there was a large section of country which had not been touched. At the same time, he would not advise anyone to go out with the idea of prospecting for individual claims. It was necessary to have capital; and those who invested judiciously would make money. The conditions in Dawson City were improving, and life and property were as safe there as anywhere, and it was now possible to obtain fresh meat, vegetables, milk, etc., so that living was tolerable.

It was resolved to prepare a petition to the Government praying that the royalty on gold extracted in the Yukon district should be reduced from 10 to 2 per cent. Friday morning was occupied in formulating the result of the election of office-bearers.

Friday Afternoon.—The scrutineers reported the result of the election of officers of the Institute as follows: President, S. S. Fowler, Nelson, B.C.; vice-presidents, C. Fergie, Westville, N.S., and Jas. McArthur, Sudbury, Ont.; secretary, B. T. A. Bell, Ottawa; treasurer, J. Stevenson Brown, Montreal; Council, for British Columbia, E. B. Kirby and Bernard Macdonald; for Ontario, Major Leckie and R. G. McConnell; for Quebec, Jas. F. Lewis and J. Burley Smith, and for Nova Scotia, G. F. McNaughton and H. S. Poole.

The point was brought up as to whether newly elected members, whose subscriptions had not been paid, should be empowered to vote or not. It was resolved to refer this question to the committee for Amendment to By-laws and Constitution.

The new president, on taking the chair, gave a short address thanking the Institute for the honor which had been conferred on him, and briefly referring to the condition of British Columbia's mining industry. While, of course, he said, the output from British Columbia was not so large as from some States to the south of them, yet it was very satisfactory, and was increasing all the time.

Arrangements for holding the summer meeting (probably at Sydney, C.B.), in connection with the American Mining Engineers were left to the council to decide. On the motion of B. T. A. Bell, seconded by J. Stevenson Brown, a vote of thanks was accorded to the retiring officers.

Major R. G. Leckie, of Sudbury, then read some Notes on the Nickel Question, which provoked an animated discussion. Canada, he said, had a good opportunity to maintain her hold on the world's nickel market, providing the industry were properly encouraged, instead of being suppressed by hostile legislation. J. M. Clark referred to the system of export duties, against which all political economists, he said, were loud in condemnation. He was utterly opposed to any such system as that proposed by the Ontario Legislature in a recent Order-in-Council, placing an export duty on nickel and copper ore exported from Canada without being first refined. Mr. Holland emphasized the remarks of the previous speaker in his condemnation of the course of the Ontario Government. That the nickel and copper interests should be vested in the Crown, and that an export duty should be placed on the ore was a most ridiculous proposition. No such legislation had ever been heard of in a British colony. If the desire of the Ontario Government had been to cripple the nickel industry of the country, they could not have devised a better scheme. He then read a series of letters from Dr. Monn, the inventor of a new process for extracting and separating nickel and copper from the ore, and who was prepared to establish large works in Ontario, providing he was not discouraged by hostile legislation. The letters went to show that it would be impossible for him to carry out his scheme, with the possibility existing of any such Order-in-Council being passed. Secretary Bell said he sympathized with Mr. Archibald Blue, a Government official, in his presence during the passing of so many strictures on his own Government; but he thought it was certainly a fair subject for discussion. It would be a serious matter if Orders-in-Council were to be passed crippling the production of asbestos, mica, and other minerals in Canada; yet, the same reasons which had been urged in favor of the Order-in-Council respecting nickel, might be urged—and just as wrongfully—against those products also. The old argument that we had a monopoly of these minerals in Canada was fallacious. It was a fact that most of the persons who had argued in favor of this new Ontario legislation were not Canadians at all, and had no interest in the Ontario nickel industry. The Canadian Copper Co., though an American corporation, was a credit to the country, and it was sad to think that just as soon as their project was becoming profitable they should be crippled in this manner. It was not right to treat American and foreign investors shabbily; and it was right that they should be allowed to make money here; this was our only argument to induce them to come to Canada again.

Archibald Blue said he could not help feeling that there was some misunderstanding among members of the institute respecting the objects of the Order-in-Council, which had been so warmly discussed. It was certainly not the purpose of the Ontario Legislature to do anything to cripple any industry in the province. Secretary Bell moved a resolution to the effect that the Order-in-Council passed Nov. 23rd, 1899, by the Ontario Government prohibiting the export of copper and nickel, except in the condition of refined nickel and copper, would prove fatal to the industry; that the imposition of an export duty on nickel matte by the Dominion Government would make it impossible for the Canadian producer to compete with foreign countries; and that a copy of this resolution should be forwarded to the Premier, the Commissioner of Crown Lands for the province of Ontario, the Minister of Finance and the Minister of Trade and Commerce, together with a reprint of the discussion which had taken place. This motion was seconded by Mr. Holland, but was subsequently withdrawn on the understanding that the matter should be fully threshed out by the council, and dealt with as that body might see fit. The other papers on the Syllabus were taken as read.

The proceedings terminated in the evening with a very enjoyable smoking concert, the music being delightfully rendered by members of the Zingari Club, Montreal.

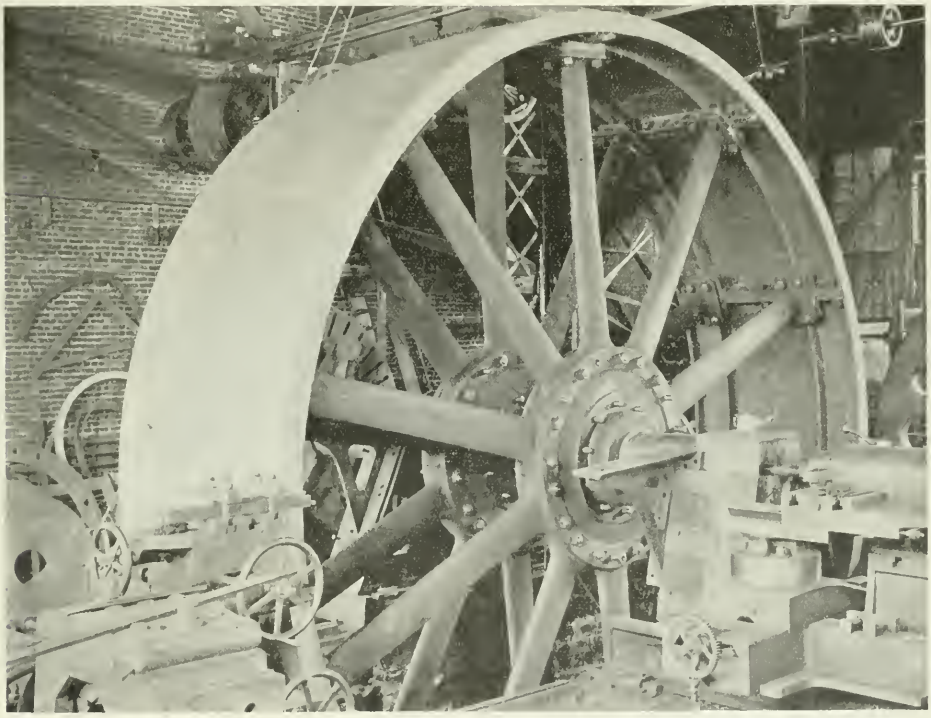
—Every good oil paint and red lead coating will protect the water reservoir from rust, and when it is perfectly dry will not give the water any noticeable side taste. The only drawback is that the oil coating does not last long. For this reason a cement coating is considered superior to oil paint. Cement dries perfectly in a few hours, and if it is made right lasts at least as long as oil paint, while its cost is next to nothing. In the Experimental Brewery at Berlin (says the Nordd Bangew Anzeiger), the lime and warm water receptacles are painted with cement, and after four years' use, the coating has not required renewal.

LARGE COMPOUND ENGINE.

The Laurie Engine Company, of Montreal, has just shipped the Ogilvie Milling Company, of Winnipeg, one of its 1,000 h.p. Corliss tandem compound condensing engines, the general dimensions of which are as follows, viz.: High pressure cylinder, 24-in. in diameter; low pressure, 48-in. in diameter, with a stroke of 48-in. The main shaft is 18-in. in diameter, the journal being 16 inches diameter and 32 inches long. The general design is what is known as the heavy duty type. The frame casting which carries the main bearing weighs 12 tons. The fly wheel pulley is 22 feet in diameter and 6 feet 2 inches across the face, the rim of which is made in ten sections with two sets of arms (ten in each set), with four heavy flanges forming the two hubs. The wheel weighs about sixty tons.

The Laurie Engine Company's method of constructing these large wheels is different to the general practice in that the parts are never assembled until the wheel is put into the lathe for turning. The sections are machined on all four angles (and completed ready for going together) on a special milling machine designed for the purpose. The arms and flanges are faced, turned and drilled to jigs, making all the parts perfectly interchangeable, so that when the wheel is put together in the lathe it is simply a matter of bolting the parts together, there being no fitting to do whatever. The securing together of this particular wheel required 240 low-moor iron bolts, each 2¼ inches in diameter. This wheel is illustrated herewith. The steam cylinders are both steam jacketed, and fitted with the company's improved double eccentric valve motion. The receiver between the cylinders is furnished with superheating tubes of seamless drawn brass.

The condenser plant is of the surface type, the condenser being of the rectangular type with 2,000 feet of cooling surface. The pumps (air and circulating) are of the vertical, crank and fly-wheel type, driven by a 14-inch Corliss cylinder. The whole engine is designed with a view to obtaining the highest possible economy. It is built extra heavy throughout (weighing about 350,000 lbs.) and reflects great credit on the builders.



FLY WHEEL OF LAURIE ENGINE CO.'S NEW ENGINE BUILT FOR OGILVIE MILLING CO.

BLUE PROCESS PAPER.

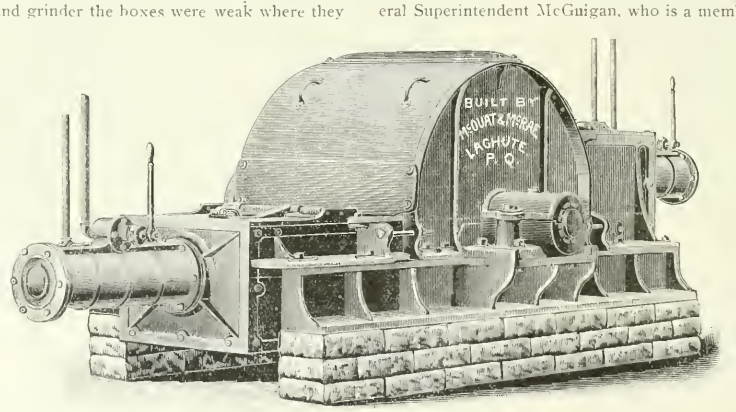
The prepared paper for this process is of a light greenish yellow tint when freshly coated. In the course of time, however, and particularly during the summer months, the paper turns to a darker tint up to a blue gray, which, however, is no indication that the paper is spoiled and unfit for use. Good prepared paper for this process will keep unimpaired at least three months. The Helios papers have been for many years generally recognized as the best for photographic and other fine work, states the Keuffel & Esser Co., in Photo-Printing from Tracings, a pamphlet recently issued. Both their printing and keeping qualities are superior to other blue print papers. Where price is more of an object than quality, the Columbia papers are generally preferred, as being the best value for the money. Cheaper papers can be bought, but they are not economical. The difference in price is small and not enough to compensate for inferior results, to say nothing of the waste of time and paper through the tearing of wet prints. When extra toughness is wanted, the Parchmine papers are used, unless light weight is also a consideration; in that case the E.T. (extra thin) papers are recommended.

Blue process papers cannot be judged by their color; only an actual test will show whether the paper is perfect or not. The exposure of blue process paper takes from four to eight minutes in bright sunlight, varying, of course, with the intensity of the light and the transparency of the material upon which the tracing is made. In the shade, or on dark and foggy days, the exposure may last up to one hour before it is completed, and on such days judgment must be used in determining its duration, and good care taken that the paper is not taken from the frame before it has been sufficiently exposed. When the margin protruding from under the original drawing has attained a greenish-bronze color, open one part of the back of the frame and observe the copy. If the lines stand out sharp and distinct on a gray background, the exposure is completed. Then take the copy from the frame and place it in a bath tray containing sufficient water to fully cover the print. Here the lines will gradually turn into white while the background is changed into brilliant blue. Rinsing

the print by means of a spray will quicken the washing. As soon as the lines stand out in clear white the print may be taken from the bath and hung up to dry, which completes the work. Remember that the fresher the paper is the slower it will print and the quicker it will wash out; the older the paper is the quicker it will print but the slower it will wash. To obtain satisfactory results never take prints from the water bath before the lines are perfectly white, although it may take hours to effect this. As soon as the bath becomes discolored, renew by fresh water, as otherwise the chemicals dissolved in the water will discolor the white lines to a bluish hue. The longer the exposure the darker the blue ground of the paper will be, but the lines of the drawing should always appear in a clear white color, provided the original shows opaque lines. The copies after drying will be darker than when they are taken from the bath. Papers printed in direct bright sunlight will generally not produce such a rich and beautiful blue background as those which are exposed in the shade.

A NEW PULP GRINDER.

McOuat & McRae, engineers and founders, Lachute, Que., have placed on the market a wood pulp grinder, which is here illustrated, and which has been strongly commended by pulp manufacturers who have tested it. This is the New England type of grinder, but of an improved make, and while the price is as low as the New England grinder, the capacity is greater, the machine has a longer life, and will run with less power. In the ordinary New England grinder the boxes were weak where they were fastened to the machine, and often ripped off. By the system of flanges and bolts adopted by McOuat & McRae, the strength is greatest where the strain is most severe. The pockets also can be made fewer and of larger capacity, and are so placed that the pressure and friction are balanced on each side of the stone. By grinding on a large surface with comparatively low pressure, the resulting fibre is longer and better preserved. The result is not only a greater grinding capacity, but easier running with less power. The machine takes a stone of 26 inch face by 50-inches in diameter, held on the shaft by flanges screwed on by right and left thread. Each pocket will admit a piece of wood 24-inches long by about 16 inches in diameter, against a piece 18-inches long in the ordinary grinder. There is therefore less waste in splinters and small pieces at the finish, and there is less stopping to fill the pockets. The Lachute grinder can be built with two or three pockets. Where a third pocket is used the balance of pressure is preserved by using the third pocket while one of the other two is being refilled. The pressure cylinders are lined with brass, and the pistons packed the same as in the hydraulic press, so that while working freely they are also water tight. Samples of these grinders may be seen in the pulp mills of Hamelin & Ayers, Lachute, and Ford & Co., Portneuf, Que., both of which firms speak in the highest terms of the efficiency of the machine. McOuat & McRae also manufacture other pulp machinery such as stuff pumps, high pressure pumps, fire pumps, calendar roll grinders, etc., which are now gaining a good name in the Canadian mills.



The Lachute Pulp Grinder

AMERICAN ENGINEERING AND MAINTENANCE OF WAY ASSOCIATION.

This association, which was formed a little over a year ago, held its first annual convention in Chicago on the 14th and 15th of March, at which there was an attendance of nearly 150 members. Over one hundred railways, covering an aggregate length of more than 140,000 miles, are represented in this association, and the membership is composed of the principal engineers and general officers of these railways responsible for maintenance of way matters.

President J. F. Wallace, of the Illinois Central Railroad, occupied the chair, and made an excellent presiding officer. Mr. Wallace also has the distinguished honor of being president of the American Society of Civil Engineers, and to him, as well as to Mr. L. C. Fritch, the secretary of the new association, is largely due the success which has characterized all the proceedings of the organization since its inception. The preliminary reports of the several standing committees were read and discussed, and judging from the work of these committees so far, the schemes and objects of this association are most comprehensive, and its high aim, and the zeal of the officers in their efforts to promote these objects were well exemplified in the plan of work. There are fourteen standing committees, and the subject-matters respectively entrusted to their investigations embrace every feature connected with the construction, operation and maintenance of railways.

The Grand Trunk Railway system was represented by General Superintendent McGuigan, who is a member of the board of direction; assistant engineer W. McNab, vice-chairman of standing committee on graduation (who presented the report of that committee), and Superintendent W. Cotter, of the Western Division. The Canadian Pacific representatives were: Chief Engineer P. A. Peterson, first vice-president, and Superintendent James Oborne, of the Western Division.

The standing committees deal with the following subjects: Graduation, ballasting, ties, rail, track, buildings, bridges and trestles, masonry, signs, fences, crossings and cattle guards, signalling and interlocking plants, records, accounts and reports, uniform rules, organization, etc.; water service, yards and terminals. Each of these fourteen standing committees has five or ten subdivisions of work, so that if the programme of the association is carried out it will prove an organization of the highest importance to the railway interests of the continent.

CALCIUM CARBIDE AT CHICOUTIMI, QUE.

One of the most important of the many developments of electricity now going on in Canada is that for the production of calcium carbide on the Saguenay River, near Chicoutimi, Que. On February 5th of this year, Thos. L. Willson, the inventor of the process of producing calcium carbide now so much used, bought from the Quebec Government the Saguenay power at tide water, which is capable of a development of 60 feet head, and would give over 200,000 h.p. At this point the Ship Shaw River falls into the Saguenay, and has quite a flow of water,

giving at its minimum about 15,000 h.p. under a development of 138 feet over the water wheels, the total fall being over 150 feet.

Here Mr. Willson proposes first, to develop 10,000 electrical h.p. on the Ship-Shaw, and a second development of 100,000 h.p. on the Saguenay, leaving a further possible power development on the Saguenay of over 100,000 h.p. When the Saguenay power is developed, this will be an excellent location for wood pulp manufacture and paper mills, as it is the centre of the finest pulp wood districts in the world. There would be also power to spare for renting to other industries, and being on tide water, and having a railway running to the works, the location would afford a most advantageous situation for manufacturing industries. The development of 10,000 h.p. in the Ship-Shaw is now proceeding.

Industrial Notes.

Edmonton, N.W.T., will build a hospital at once.

The Brockville Peat & Power Co. will install a large drier.

Graham & Johnston have moved their file works from Almonte, Ont., to Toronto.

The Toronto Cold Storage Co. has increased its capital stock from $50,000 to $100,000.

The Winnipeg mill, of the Ogilvie Milling Co., is being enlarged to 3,000 barrels' capacity.

The Manitoba Cream Separator Co., headquarters, Winnipeg; capital, $75,000; is seeking incorporation.

Murney & Baechler, sawmill, Sarnia, Ont., will install a large engine, and are now looking about for one.

The Henderson Bicycle Company, Ltd., has changed its name to The Goderich Engine and Bicycle Company, Ltd.

Sydney, C.B., town council has voted $200,000 for sewerage, water system, fire department, sidewalks, and schools, etc.

R. H. Bogart, formerly with the Rathbun Co., Deseronto, is foreman for the Canadian Wood Specialty Co., Orillia, Ont.

The Northey Co., Ltd., has been incorporated to take over the business of the Northey Mfg. Co., Ltd., of Toronto; the capital to be $350,000.

The N. L. Piper Railway Supply Co., Ltd., has been incorporated to take over the business of Noah L. Piper & Son, Toronto; capital, $40,000.

The Dry Dock & Wrecking Co., Collingwood, Ltd., has changed its name to The Ship Building, Dry Dock and Wrecking Co., of Collingwood, Ltd.

The Haliburton Lumber Co., Ltd., has been incorporated; capital, $50,000; provisional directors are, G. P. Magan, W. D. Thomas, and F. P. Brazill.

Reinhardt & Co., Toronto, have bought about 40,000 square feet of land, at St. Paul St. and Dupre Lane, Montreal, and will build a brewery, costing, it is said, $150,000.

Blakely & Ross, who are interested in brickmaking at Orangedale, C.B., have sold out their business at Halifax, and will confine their attention to brickmaking.

An emery wheel in the Frost & Woods' works, Smith's Falls, Ont., burst March 5th. This is the third accident of this sort in these works in a period of a few months.

H. H. Gervan, W. Northwood, C. J. Smith, N. C. Sparks, J. I MacCraken, Ottawa, Ont., have been incorporated as the Ottawa Furnace & Foundry Co., Ltd.; capital, $40,000.

A. E. Gazlay, A. E. Rea, Adele Bishopric, and V. Bishopric, Toronto; Lydia Gazlay, Cincinnati, O., have been incorporated as The Victoria Paper Box Co., Limited; capital, $20,000.

Doolittle & Glazier, formerly employees of D. Hibner & Co., furniture manufacturers, have formed a partnership, and are about to build a furniture factory, 60 by 150 feet, four stories high, in Berlin, Ont.

The Sanitation and Utilization of Sewage Company Ltd., Montreal, has been incorporated; capital, $50,000; for the utilization of sewer waters for irrigation purposes G. Janin, J. A. C. Madore, A. Stuart, J. B. Lapointe, I. L. Lefleur, of Montreal, incorporators.

C. W. Price is working at a steam carriage in his shop on Simcoe street, Toronto, near Adelaide street, and is said to have interested large capitalists in Montreal.

G. G. Roe, P. S. Roe, R. C. Roe, W. Edwards, and J. H. Gervan, Ottawa, Ont., have been incorporated as the Baldwin Iron Works, Ltd.; capital, $40,000; to manufacture engines, machinery, electrical plants, etc., in Ottawa, Ont.

W. A. Farrow, D. W. Moore, H. S. and H. E. White, W. Waldron, W. W. Woods, N. McAlpine, R. H. Riley, and F. Hehn, Brantford, Ont., have been incorporated as the Mechanics' Fuel Co., of Brantford, Ltd., to deal in peat, etc.

A. Pequegnat, P. Pequegnat, R. D. Lang, and S. Groh, Berlin, Ont.; L. G. Pequegnat, New Hamburg, Ont.; J. U. Pequegnat, Guelph, Ont.; and James Pequegnat, Stratford, Ont., have been incorporated as the Berlin and Racycle Mfg Co.; capital, $49,000.

The Dominion Government has recently made soundings in the Ottawa river at Des Joachims rapids, to locate the proposed new bridge to which $15,000 has been voted. The Ontario and Quebec Governments will give $5,000 each, and $10,000 will be subscribed by local capitalists.

The School of Practical Science, Toronto, will get $23,870, instead of $22,470, from the Ontario Government this year, and the professor in engineering will get $200 additional, and the lecturer in surveying $100, also the lecturers in electrical engineering, applied mechanics and mining.

The United States pipe trust is said to be shipping freely to Canada, in order to injure the Canadian makers, who are entering the United States market and finding ready sale for their pipe. Canada will cut very seriously into the United States iron trade in more than pipe when plants now contemplated come into competition.

The new iron and steel company being formed in Collingwood, Ont., by United States capitalists, among whom are several of the shipbuilding family of Philadelphia, the Cramps, has had voted a bonus of $115,000 by the town, and other inducements, such as a fine site, will be granted. The vote in favor of the bonus was very large.

The Dominion Leather Board Co., of Montreal, has put in a new 200 h.p. engine, made by the Jenckes' Machine Co., into their mills at Sault au Recollet. A new beating engine for the leather board works is also being put in, and the capacity of the works will now be one ton per day each for the leather board and paper mills. Both branches are now running night and day.

Hon. J. Dryden, Brooklin, Ont.; C. Mills, Hamilton, Ont.; D. Henderson, Acton, Ont.; W. McGregor, Windsor, Ont.; F. Fenton, M.D., Toronto, Ont.; J. H. Douglas, Warkworth, Ont.; and J. G. Boucher, London, Ont., have been incorporated as the Dominion Fence Co., Ltd., to make and deal in wire fencing, metal roofing, and siding, etc.; capital, $750,000; head office, Toronto.

Wm. R. Perrin & Co., of Chicago, have started manufacturing their goods in Canada, and have leased the plant of the Ontario Engine & Machine Co., on Richmond St. East, Toronto. J. F. Lawson, well-known to the Canadian consumers of their goods, is in charge. Mr. Holmes, of the Chicago plant, has been appointed mechanical superintendent. Their office is at 122 Church St., Toronto.

A great shipbuilding industry is proposed for Halifax, N.S., to use steel made in Sydney, C.B. The promoters speak of a capital of $20,000,000. What reason there might be for locating the ship yard so far from the source of materials is hard to see. Perhaps the people of Halifax may grant a large bonus, but otherwise it would seem natural for a shipbuilding company to avail itself of the great advantages of Sydney for such an industry.

Charles Meyers, Ottawa, who is promoting an iron smelter in Kingston, has made the following offer to that city: The company would put up a smelting works plant worth $225,000, with a capacity to smelt from 100 to 200 tons of iron ore daily; they would employ from 100 to 200 hands; they would transfer their offices, etc., there; they would pay from $100,000 to $150,000 yearly in salaries. In return, they asked from the city a free site, exemption from taxation, and a bonus of $4,000 yearly for fifteen years.

The Midland, Ont., Elevator Co. is taking out its old steam plant and putting in a new engine and boiler.

Hamilton, Ont., is to go on with its $200,000 third water main, which was voted on recently.

McLachlan Bros., Arnprior, Ont., have had their saw mills' assessment fixed at $100,000 for ten years, and $225,000 for another period of ten years.

The McLachlan Electric and Gasoline Motor Co. is busy constructing a gasoline carriage, to be worked with a double-cylinder, non-vibrating motor.

The Winnipeg Commercial states that D. McLean has organized a company to build a 200 bbl. flour mill, and a 50,000 bushel elevator at Moose Jaw, N.W.T.

A Scotch firm writes the Canadian Government offices in London, asking for names of Canadian exporters of broom, hoe, and shovel handles, prices to be quoted for car lots.

McGregor & McIntyre, the Builders' Iron Works, 65 to 71 Pearl street, Toronto, make a specialty of jail cells, iron sidewalk doors and fire escapes. They are well equipped for supplying all classes of builders' iron work.

W. T. Jennings, C.E., has been retained by Toronto to co-operate with the Dominion Government engineer, J. R. Roy, C.E., in preparing plans for the improvement of Toronto harbor.

George J. Dickson, Alex. Robinson, David Sadler and A. G. Dickson are a committee to secure the establishment of a $2,000 butter factory at Napan, N.B., under the auspices of the Farmers' and Dairymens' Association.

The Hamilton Brass Mfg. Co., has sold its cash register business to the American National Register Co., Dayton, O., for about $250,000. It is said the United States monopoly will establish a large factory in Hamilton, Ont., to employ some 200 hands.

The town of Fort William, Ont., has granted a bonus of $50,000 to the Mattawin Iron Mining Company, which is to erect a blast furnace on the banks of the river, and also one of $25,000 for a copper refinery, providing construction is commenced within six months, and finished inside of two years.

Application has been made for letters patent by the Imperial Cotton Company, of Hamilton. Among the directors of the new concern, which is to have a capital of $750,000 are W. D. Long, J. M. Young and Alfred Morgan, Hamilton, Ont., and C. T. Grantham, of Yarmouth, N.S.

J. N. Tallman & Sons, Hamilton, Ont., are enjoying a very much increased business in the manufacture of machinery, ornamental brass, phosphor bronze, zinc, copper, aluminum and aluminum bronze castings, etc. The new building, which has just recently been completed, is one of the largest and best equipped brass foundries in Canada. Among the improvements is a smelting furnace of 3,500 lbs.' capacity, for the manufacture of large phosphor bronze castings, etc. Having made extensive improvements for this class of work, orders can be filled on short notice.

The John McDougall Caledonia Iron Works, Ltd., Montreal, has been incorporated; capital, $500,000; to deal in iron and iron ore, to carry on the business of mechanical engineers and manufacturers, and to acquire the business now carried on under the name of John McDougall Caledonia Iron Works. The charter members are: E. M. McDougall, Agnes K. McDougall, Jessie E. McDougall, F. C. Henshaw, L. B. McDougall, wife of J. D. Hayden, Cobourg, Ont., and R. Cowans, Montreal.

Two hundred men employed by the Hamilton Ont., Steel and Iron works, went out on strike March 31st, causing the laying off of 150 other workers and the closing of the works. The strikers were employed as finishers in the nine and ten-inch mills and claim that under the western scale of the Amalgamated Association of Iron and Steel Workers of America, they were entitled to an advance of 4 per cent. in their wages on March 1st, and as this advance was not received, they struck. The workers in the finishing departments number 150 and were compelled to quit work when the other men went out. The men employed at the Hamilton Bridge Works struck a short time earlier. The works are being overhauled, taking advantage of the men's absence.

The use of steel in large buildings is causing an increased demand for hoisting engines. In the past year M. Beatty & Sons, Welland, Ont., have supplied eight special hoisting engines to the Dominion Bridge Co., and in one month four to the Dominion Iron & Steel Co., Sydney, C.B. The United Coal & Coke Co., Sydney, C.B., has bought one such engine, and the revolving and travelling derricks are now being built in Welland for the Hamilton Steel & Iron Co., for unloading at the docks in Hamilton.

The Still Motor Co., Ltd., 710 to 724 Yonge St., Toronto, has been purchased by English capitalists, who are forming a large company, called "Canadian Motors, Limited." The factory is crowded with orders for twelve months ahead. The automobiles manufactured are motets, Gladstones and delivery wagons, equipped with motors, batteries and controllers, under the Still patents. W. J. Still, the inventor, is now in England with the Oxford carriage, which was manufactured here. To Thomas Bengough is due the chief credit for the successful flotation of the Still business.

The seventy-third meeting of the Mechanics' Society, of Newfoundland, was held in St. John's last month. The reports from the Higher Council and officers showed the institution to be flourishing, that of the former expressing a removal of certain disabilities under which the boiler-makers and tanners labored. The officers installed were: President, T. M. White; vice-president, J. P. Scott; 1st assistant, C. Nurse; 2nd assistant, T. Rourke; treasurer, M. W. Myrick; 2nd treasurer, James Beck; 3rd treasurer, J. Goodland; secretary, J. J. Mullaly; grand marshal, Peter Stapleton.

A trial was made last month of the pumping plant of the Verdun, Que., sewerage system. This plant consists of an eighteen-inch centrifugal pump of the Northey Manufacturing Co.'s make, and a boiler and engine from the Caledonian Iron Works, Montreal. The engine pulley is ten feet in diameter and eighteen inches face, that of the pump shaft being forty inches by eighteen, the whole housed in a neat brick building, fifty by forty feet. (The purpose of the pumping plant, it should be said, is to get rid of the sewage when the river is at flood). The stipulated delivery by the pump was exceeded in the actual working, and the entire plant met with approval.

At the sixth annual meeting of the Nova Scotia Steel Company, the directors' report showed that business done in 1899 was the largest in the company's history. A dividend of four per cent. on preferred stock for the half year ending December 30th, 1899, was declared. On this stock four per cent. had previously been paid in June, 1899, and 24 per cent. in August, 1899. The dividend just declared makes 32 per cent. earned by preferred stock for the year, and pays all accrued dividends up to 1900; 8 per cent. was declared on common stock, payable March 10th. This is the first dividend paid on ordinary shares since the amalgamation of the company in 1895. The profits for the year, after paying floating debt, 28 per cent. dividend on preferred stock, and $75,300 bonds, were $819,945. In these profits, of course, are included $1,000,000, the price of the iron ore mine at Wabana, Nfld., sold by the company to the Dominion Iron & Steel Company.

A meeting of the organizers of the Canadian Steel Company, the incorporation of which, with $18,000,000 capital, $3,000,000 preferred, is now pending, was held in this city this week, says The Journal of Commerce, New York, under date March 28th. At this meeting details of the organization were agreed upon, although the formal organization cannot be effected until the charter has been actually issued, which it is expected will be done about the 20th of next month. The plant of the company will be at Welland, Ont., where a 1,500 acre site has been obtained. This is at the mouth of the Welland Canal, where it is said Lake Superior ores can be laid down as cheap as at Cleveland or Buffalo. The company proposes to enter into practically all departments of the iron and steel business. Among those interested are several capitalists from this and other cities of the United States, while Canadian capital is also concerned. A feature of the company's charter is that it will permit the company to make contracts for electric power with the Hamilton and Lake Erie Power Company, specifically, or with other companies. It is claimed that power can be furnished in this way at about one fifth the cost of steam power in Pittsburg.

A Wren & Co.'s foundry, Forest, Ont., was burned, March 29th; loss about $5,000.

John Wheeler, needle maker, Paris, Ont., is asking for exemption from municipal taxation.

J. K. Brydon, Rat Portage, Ont., is to build a business block, part of which will be occupied by the Bank of Ottawa.

Simon Peters Co., Ltd., is to be incorporated to do business in Quebec as general contractors, lumber merchants, etc.; capital, $100,000.

The Montreal Rolling Mills were badly damaged by fire, March 24th. The business of the company will not be delayed however. The capital of the company will be increased to $750,000.

M. H. Frost, A. R. Gilbert and J. Brown, Cleveland, U.S.; H. L. Frost, and Clara M. Frost, Welland, Ont., have been incorporated as the Frost Wire Fence Co., Ltd.; capital, $40,000; chief place of business, Welland, Ont.

C. J. Anderson, P. Stenins, G. Everson and W. A. Carlson, Detroit, U.S.A., and A. Lovett, Colchester, North Essex Co., Ont., have been incorporated as the Walkerville Match Co., Ltd.; capital, $100,000; chief place of business, Walkerville, Ont.

A. Bell, judge; A. Park, J. Piggott, M. Wilson, Q.C.; E. R. Smith, W. F. O'Hara, D.L.S., Chatham, Ont.; S. A. King, Kingsville, Ont.; R. Aikin, J. I. Wiley, M.D., Dresden, Ont.; T. L. Pardo. and W. D. Samson, Blenheim, Ont., are incorporated as the Western Peat Fuel Co., Ltd.; capital, $100,000.

J. Hewer, H. H. O. Stull, T. Davidson, W. E. Buckingham, and W. J. Hammill, Guelph, Ont.; A. J. McPherson, Stratford, Ont.; and R. M. Duvall, Springfield, Mass., have been incorporated as the Ontario Seed and Grain Separator Co., Ltd., to make agricultural implements; capital, $40,000; chief place of business, Guelph, Ont.

Redpath-Reid automatic smoke consumers have recently been supplied by the Jubilee Grate Bar Co., Ltd., to the following among others: A. & J. Clark, Bullock's Corners, Ont.; Dunn Spice Mills, Hamilton, Ont.; Hamilton Times, Hamilton, Ont.; T. Upton & Co., Hamilton, Ont.; Penman Mnfg. Co., Paris, Ont.; R. G. McLean Printing Co., Toronto; Verity Plough Co., Brantford, Ont.; Pugsley, Dingman & Co., Toronto Junction, Ont.; Kingdon, Smith Co., and Victor Soap Works, Hamilton, Ont.; P. W. Ellis & Co., Toronto. The company also reports an unprecedented demand for shaking grates.

The Cummer mechanical dryer is approved of by the Fraser River Oil and Guano works, Vancouver, B.C., which writes to the F. D. Cummer & Son company: "The 'F' dryer will easily dry from 50 to 60 tons of fish scrap per day of 24 hours. It is very satisfactory and economical of fuel and labor. It is the best on the market." The Trent Valley Peat Fuel Co. states that a Cummer dryer "evaporated at the rate of 4,565 pounds of water per hour; consumed 414 pounds of combustible per hour; one ordinary workman operates the entire dryer plant. The product obtained is uniformly dried and in excellent condition for pressing."

An explosion occurred at the gas works of the Listowel Gas and Electric Light Company, Listowel, Ont., March 23rd, at 11.30 o'clock p.m. The generator blew up and wrecked the building. The engineer of the works, William Bitton, was in the building at the time, and was carried out before the fire, which at once followed the explosion. He was badly injured, one of his thighs being fractured, and his body being cut and terribly bruised in different places. The force of the explosion shattered all the windows in the neighborhood, and broke plate glass more than a quarter of a mile away. The electric-light plant was in the same building, and was also completely wrecked. The gas company last summer put in a new plant, changing from oil gas to water gas. The insurance was $3,000 on the gas plant, and $800 on the electric light plant.

The Smart-Eby Machine Co., Ltd., is at present working on the following orders: Twelve electro reduction baths, two mixing machines 6-ft. by 12-ft., ten steel tanks 12 ft. diameter by 10-ft., one 30,000 lbs. travelling crane, one 30 h.p. boiler fitted with Rodgers patent shaking and dumping grate bars, 350 feet steel shafting with hangers, etc., for the Hoepfner Refining Co; one 50,000 lb. travelling crane, and 800 rain proof pulley blocks for the Hamilton Electric Light & Cataract Power Co; two alligator shears, each direct connected to its own engine; one 7½ x 4½ x 10 outside packed boiler feed pump, ten steel charging buggies, one ladle heater, for the Hamilton Steel & Iron Company, two travelling radial drills with 20 foot arms for the Hamilton Bridge Works Co., one ten h.p. high speed vertical engine, one 20 h.p. boiler with Rodgers' patent shaking and dumping grate bars, with shafting, pulleys, etc., for the Hamilton City Hospital laundry; one end bending machine for bending extra heavy bob runners, and one stack bender for bending wagon shafts, for F. W. Hore Sons; one eight can drying machine for the Guelph Carpet Mills Co.; one double disk sander for the Ontario Box Co.; one internally fired boiler for Smith & Baker, Dundas, Ont.

Railway Matters.

R. Sheehy, Peterborough, is building the new Roman Catholic church in Campbellford, Ont.

Reid McManus, C.E., is in charge of the ten-mile contract on the P.E.I. Railway, held by his father, J. W. McManus.

The Grand Trunk Ry. Co. has adopted the new Milne cushion truck brake for use on the passenger rolling stock.

The freight bill of the Dominion Iron & Steel Company, of Sydney, C.B., for the month of January, amounted to something over $82,000, it is said.

The C.P.R. has ordered from the car shops at Perth 100 standard 30-ton flat cars, 200 standard 30-ton box cars, 75 standard 30-ton refrigerator cars for freight service, and 25 refrigerators for the passenger service. The order is to be completed by the 1st of June.

During the present year, the Grand Trunk Ry. Co. intends to expend $800,000 on the Midland Division, to include a new station at Queen street east, Toronto, a new turn table at the round-house, and the double tracking of the line from Niagara Falls to Hamilton, Hamilton to London, and London to Sarnia.

The Great Northern Ry., for which John Ross, Toronto, has the contract, will be finished by August 1st. The bridge at Hawkesbury will be a prominent feature. One span of the steel work has already been put in position. Forty miles of the road have been operated this winter between St. Jerome and Ste. Elizabeth, Que.

The Canada Atlantic Ry. shops at Ottawa, in which work was interfered with a short time ago owing to the scarcity of material, have resumed operations, and are now running on regular time. The company proposes to build about seven hundred freight cars before July 1st, and the heavy undertaking will necessitate the permanent employment of a large staff of men.

The Canadian Pacific Ry. is surveying a new route from Ottawa to Arnprior, Ont. The present road from Arnprior to Ottawa, by way of Carleton Place, is almost double the distance of the proposed short line. The proposed new road is to run parallel with the Ottawa river, and between it and the Ottawa, Arnprior and Parry Sound Ry., traversing the townships of Tarbolton and Fitzroy.

Two branch lines of railways are likely to be built in the Ottawa Valley during the coming season, one to be known as the Bancroft and Pembroke Ry., is to be built from the former to the latter place to connect with the Canada Atlantic Ry. at Pembroke, shortening the distance from Pembroke to Toronto over 80 miles. At Bancroft the line would connect with the Grand Trunk Ry. The other is the North Lanark Ry., which will run from Mud Lake on the Kingston and Pembroke Ry. to Arnprior, and there connect with the C.P.R and C. A. Rys.

The Grand Trunk Ry. will rebuild the International bridge over the Niagara river at Black Rock, below Buffalo. The bridge was built in 1870. The official announcement states that arrangements have been made for the renewal of the superstructure of the bridge, the property of the International Bridge Co., controlled by the Grand Trunk. There are two independent structures. One is the bridge across the Niagara proper, the other across Black Rock Harbor. The bridge

across the river consists of eight spans and has a length of 1,967 feet. Two openings are bridged by the arms of the draw girder, which has a length of 362 feet. The bridge across Black Rock Harbor is 517 feet. The draw span of this bridge has an opening of 107 feet. This work is being done to meet the requirements of the increasing weight of rolling stock. The contract is let to the Detroit Bridge and Iron Works.

At the annual meeting of the C.P.R., held April 4th, a statement including the following was made: A balance sheet of the affairs of the company at December 31st, 1899, shows the gross earnings for the year were, $29,230,038.26; the working expenses were $16,999,872.77; and the net earnings were $12,230,165.49. The working expenses for the year amounted to 58.16 per cent. of the gross earnings, and the net earnings to 41.84 per cent., as compared with 59.92 and 40.08 per cent. respectively in 1898. The earnings per passenger per mile were 1.79 cents, and per ton of freight per mile 0.74 cents, as against 1.52 and 0.76 cents respectively in 1898. During the year, two hundred and seventy-four miles of the main line were relaid with steel rails weighing seventy-three and eighty pounds per yard. The land sales for the past year were 416,806 acres for $1,327,667, as against 348,608 acres, for $1,121,774, in 1898.

Electric Flashes.

The Record Printing Co., Windsor, Ont., has bought from the Electrical Construction Co., London, Ltd., a 40-light multipolar dynamo.

J. A. Humphrey & Co., Toronto watch case manufacturers, have installed a new plating dynamo of the Jones & Moore Electric Co.'s manufacture.

The new firm of Raney Specialty Mnfg. Co., Kingston, Ont., has bought from the Electrical Construction Co., London, Ltd., three motors for its new works.

The Erie Iron Works, St. Thomas, Ont., has ordered from the Electrical Construction Co., London, Ltd., a 12 h.p. motor, which has already been installed to their satisfaction.

The Electrical Construction Co., London, Ltd., has sold twenty-two of the list of eighty second-hand machines which were recently exchanged for new ones in Winnipeg.

The installation of the electric lighting plant at the dry-dock sub-station, St. John's, Nfld., is under the superintendence of W. A. Mackay. The entire plant is supplied by the Westinghouse Electric Co.

The W. J. Gage Co., Toronto, has bought two new motors from the Electrical Construction Co., London, Ltd., in addition to the two slow speed press motors which had already been bought from this company.

H. McCulloch, sr., has retired from the board of directors of the Galt, Preston & Hespeler Ry., and M. N. Todd has been elected president in his stead, and G. Forbes, of Hespeler, a director. W. H. Lutz was re elected secretary treasurer.

The Nova Scotia Electric Light Co. has had a second survey made of the source from which it is intended to derive the electrical power for the Annapolis Valley. The engineer's report was satisfactory, and the company is making plans to commence work at once.

The Shawenegan Carbide Company, Ltd., has been incorporated with a total capital stock of $1,000,000, the charter members being: D. D. McTavish and T. L. Wilson, St. Catharines; A. E. Plummer, John Payne and Wm. Gilchrist, Toronto, and Clarkson Freeman, Merritton, Ont.

At the annual meeting of the Hoepfner Refining Co., Hamilton, Ont., the following officers and directors were elected: Hon. J. M. Gibson, president; J. V. Teetzel, Q.C., vice president, J. Patterson, secretary; J. Moodie, sec. treas., Carl Hoepfner, H. R. Leyden and A. T. Wood, M.P.

Work has been started on the construction of the new power transmission line to run along the mountain from the Cataract Power Co.'s station at DeCew's Falls to Hamilton, Ont. The work was commenced just south of Stoney Creek, and it is expected that the line will be ready for operation July 1st.

J. A. Culverwell, Toronto, has been appointed managing director of the Central Ontario Power Company (proprietors of the Burleigh Falls water power), of which Hon. R. Harcourt and Hon. Peter McLaren are directors. Mr. Culverwell has moved from Toronto to the company's office at Peterborough.

The new Century lamp guard, which is being placed on the market by the Packard Electric Co., Ltd. St. Catharines, Ont., is attracting favorable notice on account of the convenience in packing, as they nest and so occupy much less space than otherwise. The socket fastenings are the same as on the Perfection guards.

Iron trolley pole brackets are now being manufactured in Canada by the Builders' Iron Works, 65-71 Pearl street, Toronto. This concern also carries in stock steel and iron bars, steel angles, channels, tees, etc., and are prepared to tender on any builders' iron work, fire escapes, etc., which the completely equipped plant enables them to produce at short notice.

The Jones & Moore Electric Co. has recently booked orders for complete warehouse private telephone systems for G. R. Renfrew & Co., Watson & Co., Wyld, Grasett & Darling, Monetary Times, all of Toronto; A. A. Matthews & Co., have placed an order with the Jones & Moore Electric Co., for a complete lighting plant, dynamo, engine and marble switch-board for their new steamer "Tilly."

The London Cold Storage and Warehousing Co., London, Ont., has ordered from the Electrical Construction Co., London, Ltd., a 30 k.w. direct connected generator and engine for 250 volt service to supply the lights of the building and two motors of 10 and 15 h.p. respectively, which have also been ordered of the Electrical Construction Co., London, Ltd., of the Perfection type multipolar machines.

The Jones & Moore Electric Co. has recently furnished the following manufacturers with electric motors: Barchard & Co., G. Wellings, C. Wilson & Son, Hemming Bros., Turnbull & Russell, J. S. Bennett, A. R. Williams Co., R. A. Winton, Elliott Mnfg. Co., Chandler & Massey, Minerva Mnfg. Co., Bradshaw & Co., J. E. Dunham, J. E. Ellis & Co., the Featherbone Corset Co., Sexton & Co., J. Cohen.

The cable steamer "Faraday" finished landing at Canso, N.S., the short end of the new cable for the Commercial Company, which is to connect Canso with the Azores. Alexander Siemens, director of the celebrated firm of cable manufacturers, which has a contract for this work, personally superintended the work of landing the cable, which was successfully accomplished. The "Faraday" then proceeded paying out the cable, which will land at Fayal.

The Kneeland Reflector Co., 222 Friend street, Boston, Mass., manufacturer of reflectors, is putting on the market a new shade called Hood, and carries a stock of finished goods in silver bronze, green bronze and green enamel. All the goods manufactured by this company are said to be standard and can be relied upon to give satisfaction. S. R. Kneeland, of the company, is the original manufacturer and patentee of reflectors known for ten years as McCreary Standard Reflector Shades.

Judgment was given in the Court of Appeal last month in the case of Harris v. Toronto Electric Light Co. Judgment on motion by plaintiff for order directing that upon the new trial directed by the court to take place, the sole question to be determined shall be how the fire which destroyed the plaintiff's premises was caused. Order made directing a new trial generally on all questions raised, except that of damages. Costs of this motion to be considered as part of the costs of the appeal. J. B. Clarke, Q.C., and Swabey for plaintiff. Aylesworth, Q.C., E. F. B. Johnston, Q.C., and Henry O'Brien, Q.C., for defendants.

The Lachine Rapids Hydraulic and Land Co. has within the last two months installed three new generators of 1,000 h.p. each, and a fourth generator of the same power is now on the way, thus increasing the capacity of the works by 4,000 h.p. This machinery was supplied by the Canadian General Electric Co. Some changes have recently been made in the method of driving the exciters at the power house. Instead of being driven from the main shaft they have been put in brick buildings and driven by independent wheels. The company has recently put in lathes, drills and a planer, and have equipped a blacksmith shop, these to be used as a repair shop.

The Chambly Power Co. proposes to build a second dam across the Richelieu River, about two miles above the present dam. This new work will serve the double purpose of preventing the occasional formation of frazil ice at the lower dam, and will furnish 9,000 or 10,000 additional horse-power for transmission to Montreal. It is expected that the Montreal Street Railway will take at least a part of this new supply of electricity. At present at certain hours of the day the demand for lighting and manufacturing purposes takes all the current sent to Montreal, but at other hours much goes to waste; but it is proposed to store the waste power in storage batteries, and use it all up in the hours of greatest demand. It is expected that the plans will be settled on the return, from England, of Mr. Ross, who is interested in both companies.

At the twentieth annual meeting of the Bell Telephone Company of Canada the annual report showed that 2,841 subscribers had been added during the year, the total number of sets of instruments now earning rental being 34,923. The company now owns and operates 343 exchanges and 450 agencies. To the long distance system, 1,686 miles of wire were added in 1899. The net revenue for 1899 was $353,307.40, the dividends amounted to $312,920, leaving a balance of $40,387.40, which, added to the balance revenue from 1898 of $149,735.98, leaves $190,123.38 to be carried forward to 1900. The plant and patents to the end of 1899 are valued at $5,244,436.33. The following directors were elected: C. S. Sise, president; Chas. Cassils, R. Archer, Robt. Mackay, vice president; H. Paton, W. R. Driver, John E. Hudson and T. Sherwin.

Personal.

W. F. Van Buskirk, C. E., has been appointed city engineer of Rossland, B.C.

Wm. Reid, a well-known contractor and builder, Montreal, died last month at the advanced age of 82 years.

Kenneth Mackenzie has spent some time in Canada recently and will report upon the Ottawa-Georgian Bay Canal plans.

The secretary of the Petrolea Electric Light Co., Walter McDonald, died at his home in Toronto, recently, after a short illness.

George Simpson, assistant engineer of the Northern Pacific Ry., has resigned his position to accept the position of chief engineer of the Manitoba Provincial Government.

H. F. Duck, manager of the Engineering Contract Co., Temple Building, Toronto, was among those injured in the C.P.R. accident at Myrtle, Ont., last month. Mr. Duck has entirely recovered.

The employees of the Verity Plow Co., Brantford, made a handsome presentation to R. H. Verity, manager of the company, on the occasion of his resignation to accept the position of assistant manager of the Massey-Harris Co., Ltd.

Locomotive Foreman John Donnelly has been transferred from the G.T.R. yards at York, Ont., to Montreal, where he will succeed G. Blackbird, who was formerly locomotive foreman at that point. Traveling engineer W. Newcome will take John Donnelly's place at York.

Wm. Wallace, of Prescott, an old employee on the C.P.R. between Ottawa and Prescott, died suddenly from a stroke of paralysis a short time ago. He was stricken while being presented with a gold watch and chain by a number of his fellow-employees on the C.P.R.

S. Walker, who has been for almost 17 years foreman in the G.T.R. workshops, Point St. Charles, Montreal, was presented with a silver tea service, a marble clock and a bronze lamp by the employees, on his leaving the employ of the G.T.R. to become general foreman of the Dominion Bridge Co.

R. M. Wanzer, founder of the Wanzer Sewing Machine Company, of Hamilton, Ont., died in New York on the 23rd ult. Mr. Wanzer was one of Hamilton's wealthiest and most progressive citizens, and was at one time principal owner of the Hamilton Electric light plant, and also manufactured the Wanzer lamp. Business reverses overtaking him, his fortune was soon used up and latterly he had lived in the United States.

A. P. Polson, son of William Polson, of the Polson Iron Works Co., Toronto, was almost instantly killed at Pittsburg a short time ago. Mr. Polson had charge of one of the departments in Jones & Laughlin Co.'s steel works, and while superintending the construction of a large engine was struck on the head by a flying piece of iron. He was 37 years of age, and served his apprenticeship in his father's works. He left Toronto about a year ago for Pittsburg.

G. B. Reeve, the general traffic manager of the Grand Trunk, will leave the service of the company on the last day of this month, and enter upon a new life which he has been planning for the last twenty years. That life will be spent amid orange groves and grape fruit, in a temperature which will be equable the year round, and in an environment which will realize an ideal Mr. Reeve has long cherished. He will retire to his splendid property near Los Angeles, Cal.

The many friends of Alexander Fraser were much grieved by his death last month in Toronto. He was the son of the late Archibald Fraser of Fraserfield, Glengarry, and 42 years of age. Mr. Fraser has been treasurer of the Boiler Inspection Insurance Company for a number of years. He was one of the oldest and most enthusiastic members of the Argonaut Rowing Club, and was exceedingly popular among his fellow-members, having held the position of treasurer for over ten years. He was a first-class oarsman, and was president of the Northwestern Rowing Association.

Thomas Henry, district passenger and Canadian freight agent of the Northern Pacific Ry., with headquarters in Montreal, has been appointed general traffic manager of the Richelieu & Ontario Navigation Company, in the place of the late Geo. Brown. Thomas Henry, who is 32 years of age, and a native of Montreal, entered the employ of the Ottawa River Navigation Company about twenty-one years ago, and later on that of the Grand Trunk Ry., working for the latter at the ticket office on St. James street. For the past fifteen years he has been with the Northern Pacific Ry., for ten years holding the appointment he is now resigning.

Marine News.

Tug "T. Maitland," built last winter at Owen Sound, Ont., sunk at her moorings last month in 15 feet of water.

J. B. Fairgrieve & Co., Hamilton, have appointed on the steamer "Arabian," Captain O. Patenaude, and Engineer Jas. Smeaton.

The Matthew's Line, Toronto, has appointed to the steamer "Clinton," Capt. W. J. Shaw, Engineer George Wilcox.

The Montreal Harbor Board have been discussing the possibilities of an ice breaker for use between Quebec and Montreal in winter. The Karmak model is suggested.

The issue of $386,000 new stock by the Richelieu & Ontario Navigation Company has all been subscribed privately by the present shareholders, and will not be offered to the public.

Richard Williamson, Niagara Falls, N.Y., who has bought the steamer "Myles," from Thos. Myles' Sons, Hamilton, Ont., has appointed J. O. Moore captain for this season.

North-West Transportation Company, Ltd., Sarnia, Ont., has appointed on the steamer "Monarch," Captain E. Robertson, Engineer Thomas Bard; and on steamer "United Empire," Capt. John McNab, Engineer S. Brisbin.

The St. Lawrence & Chicago Steam Navigation Co. has appointed to the steamers "Algonquin," Capt. James McMaugh, Engineer James H. Ellis; "Rosedale," Captain Jas. Ewart, Engineer Edward O'Dell.

At the annual meeting of the Richelieu & Ontario Navigation Company the report of the president and directors for the year ending December 31st, 1899, was as follows: The gross receipts were $828,322.06; 1898, $728,043.07. Operating expenses, 1899, $674,626.89; 1898, $590,036.53. Fixed charges, 1899, $24,966; 1898, $25,070.80. Net profit, 1899, $128,730.07; 1898, $112,027.55. Two semi-annual dividends of 3 per cent. each, amounting together to $104,400, were paid, leaving the amount of $24,330.07 carried to surplus.

James Playfair & Co., Midland, have made these appointments for this season: Steamer "St. Andrew," Capt. W. H. Featherstonhaugh, Engineer Thos. Crossley; steamer "Magnolia," Capt. R. H. Gilbertson, Engineer A. E. House; steamer "Metamora," Capt. James Tindell, Engineer George N. Smith; steamer "Minataga," Capt. Edward Burke, Engineer James McGregor; steamer "Margherita," Capt. James O'Connor, Engineer Henry Hewitt.

The Northern Navigation Company, of Ontario, Ltd., has made the following appointments for the season of 1900:

Steamer.	Captain.	Engineer.
Majestic	P. M. Campbell	W. J. Asten
City of Collingwood	W. J. Bassett	C. Robertson
City of Midland	F. X. La France	Wm. Whipps
Germanic	R. D. Foote	Jos. Asten
City of Toronto	John O'Donnell	D. McQuade
Atlantic	Jas. Wilson	H. Clelland
City Parry Sound	Ernest Walton	James Smith
Britannic	C. A. Jacques	Samuel Beatty

The Toronto Ferry Co., Ltd., has made these appointments for the season:

Steamer.	Captain.	Engineer.
Mayflower	G. Moulton	E. Abby
Primrose	R. Williams	S. A. Mills
Shamrock	T. Jennings	Isaac Jamieson
Thistle	A. Martin	W. Hopkins
Island Queen	M. Corcoran	T. Good
Luella	C. H. Tufford	J. Smiley

The following appointments have been made in the Montreal Transportation Co.'s fleet for season of 1900:

Steamer.	Captain.	Engineer.
Active	John Gaskin	John Hamilton
Bronson	Joseph Murray	Robert Hepburn
Bannockburn	Alex. Milligan, Jr.	Richard Taylor
D. G. Thompson	Jas. Murray	Geo. Henderson
Glide	Thos. Murphy	M. Rankin
Glengarry	Gordon Kean	Chas. Napper
Jessie Hall	Chas. Martin	Geo. Tuttle
Rosemount	Jas. Mawdesley	John Evans

The Calvin Co., Ltd., Garden Island, Ont., has made the following appointments for 1900:

Steamer.	Captain.	Engineer.
India	A. H. Malone	Thos. C. Smith
Bothnia	Geo. A. Brian	Robt. Veech
D. D. Calvin	Chas. Coon	W. H. Cunningham
Reginald	John Doyle	John Kennedy
Chieftain	John Sullivan	Thos. Gray
Parthia	David Lefave	George Sauvé
W. Johnston	Chas. E. Felix	Thos. Campeau
Blue Bell	John Dix	Chas. Le Riche

The Richelieu & Ontario Navigation Co. has made the following appointments to the various steamers of the fleet for this season:

Steamer	Captain.	Engineer.
Quebec	L. O. Boucher	F. Gendron
Montreal	L. St. Louis	F. X. Hamelin
Berthier	C. Gonin	E. Arcand
Terrebonne	E. Gonin	A. de Martigny
Chambly	J. A. S. Paulet	C. Gendron
Three Rivers	F. St. Louis	J. Matte
Laprairie	P. McLean	G. Gendron
Hochelaga	H. Mandeville	F. Chapdelaine
Longueuil	F. Jodoin	N. Beaudet
Hosanna	D. Mongeau	E. Gendron
Mouche a Feu	F. Crepeau	B. Plantal
Sorel	A. Berthiaume	F. Beaucage
Saguenay	C. Lapierre	P. Hamelin
Canada	Jos. Dugal	F. Denis
Carolina	G. Riverin	M. Latulippe
Toronto	H. Esford	Wm. Black
Hamilton	A. J. Baker	R. Marshall
Spartan	H. P. Grange	N. Beaudin
Corsican	John McGraw	W. Parker
Algerian	D. Mills	Hazley
Bohemian	A. Dunlop	A. R. Milne

The Georgian Bay Navigation Co. has recently ordered a 300-light dynamo from the Electrical Construction Co., London, Ltd., for one of its boats, to take the place of a 150-light dynamo installed two years ago by the same company, which has given every satisfaction.

It has been announced that in order to meet the requirements of its growing trade, between Cape Breton and Boston, Mass., the Dominion Coal Company has decided to have three large steamers built in Newcastle, Eng. It is understood that each will have a capacity of 6,000 tons, and a speed of 20 knots.

A serious accident occurred March 19th, on the tug "Ymir," at Kootenay Landing, B.C., when R. L. Brown, chief engineer, and Hedley St. Clair, second engineer, were scalded by escaping steam. The engineers were overhauling when a valve broke; the steam rushed out and enveloped them from head to foot. Both were frightfully burned.

The Richelieu & Ontario Navigation Co. has placed under contract a sister ship to the "Toronto," to be called the "Kingston." The new boat will be 14 feet longer than the "Toronto;" the interior fittings, etc., will all be designed by Bond & Smith, architects, Toronto, whose work in the "Toronto" we have referred to at length in former issues.

Mining Matters.

Owing to the amount of space devoted to the report of the Canadian Mining Institute meeting the Editor has been obliged to hold over a large amount of mining news.

The Pembroke Observer says: J. W. Munro has secured, in bond, the Gallagher coal oil well on Allumette Island.

The deep well of the Standard Oil Co., at Inwood, Ont., is said to have proved a failure. A depth of 2,700 feet had been reached.

Sir Wm. Macdonald is about to endow the teaching faculty of mining and chemistry at McGill University, Montreal, with additional sums amounting to almost a quarter of a million dollars.

The Parry Sound district has been recently visited by Dr. N. Lehuen, St. Paul, Minn., on behalf of those interested in the Parry Sound Copper Co. After examining the Wilcox mine on Spider Lake Bay he estimated that the copper ore in this property to the depth to which the shaft has now been sunk might be valued at $9,000,000. This is one of a number of promising properties in this district, and large development is looked for.

The Hamburg Amerian Line and Norts' German Lloyd's are each having their new two mail vessels fitted with ice-making and refrigerating machinery. These steamers are now being built by the Vulcan Works, Stettin, for the mail service between Germany, Australia, and China, under contract with the Government. One of the vessels has already left on her first voyage, and a matter of interest is that in addition to the usual cold chambers and ice-making plant, two of the staterooms have been cooled. One of these was recently occupied by Sir Claude Macdonald, on his return to China, and the cool atmosphere added great additional comfort to the voyage. We believe this is the first instance of staterooms being cooled by means of refrigerating machinery, though in several cases such machinery is used for cooling dwelling houses on land. We think that there will be a wide field for this special application, and it will certainly add enormously to the comfort of passengers during a voyage through tropics.

Whitcomb Planers .....

SEWAGE PURIFICATION BY BACTERIA.

BY W. M. WATSON.

Purifying sewage by bacteria culture is fast growing beyond the experimental stage, and has evidently come to stay. The method is both sensible and natural, and is simply assisting the bacteria that the foul fluid contains to remove the filth from the water. We have shown in previous articles that we can help the bacteria to clean the sewage by fixing the plumbing, so that plenty of air is discharged into the sewers along with the sewage, and by constructing our sewers in a way that the flow is rapid, and that every inch of the drains has a thorough circulation of air through it. By doing so, the process of bacterial sewage purification commences immediately the sewage enters the waste water pipes.

For over a century, thinking men have been trying to find out nature's way of cleansing filthy fluids, but poor success attended their labors until a few years ago, when the fact was made plain that there were creatures that could not be numbered or seen by the naked eye, whose duty it was to purify and clean objectionable matters. The varieties of these minute animals, named bacteria, are numerous and interesting; so are their appointed duties; some encourage and assist in the growth of life and vegetation, while other classes destroy such life and foster putrefaction.

The waters and air are full of germs. Their habits do not materially differ from other animals, or insects that can easily be seen by the unassisted eye, for we are told that some bacteria can only live where air cannot penetrate, others can only live by securing a regular supply of air or oxygen, and one division feed on the flesh of another division; so that a striving for the mastery is always going on in the world of microbes. This fact gives man the advantage of being able to use these invincible bacteria to keep things sweet, clean and wholesome, by constructing machines that will encourage the friendly bacteria to lodge, to lay wait, catch and destroy, that class of bacteria that injures our health and fouls our waters. When clean water is turned to sewage, the process means that dead and living microbe substances, of an objectionable kind, have taken possession of the water and compelled the friendly ones to be on the defensive.

Up to the present date, only a few experimental plants have been constructed to purify sewage on strictly bacterial lines, while hundreds of works have been built to clean sewage by sieving, by using precipitants to separate the solids from the liquids, and by passing sewage through land. Some of these methods have appeared to be successful for a period, until the land got sewage sick, and the soil was unable to receive atmospheric air sufficient to keep the cleansing bacteria active when the sewage farm became a putrid, stinking mass and the people's money had been wasted.

About two years ago the Imperial Government appointed a committee to investigate and test the several improvements made in the art of purifying sewage, and carefully study their details, with a view to securing some safe and reliable system or systems that could be recommended, and would give the taxpayers proper value for the money they expended, besides insuring the rivers from being further contaminated with sewage works effluents, that are often as injurious to the fresh water streams as the raw sewage would be if discharged into the rivers unsieved and untreated. I am informed that the Royal Commission has about completed the testing and experimental work, and is, I believe, now preparing its report, which will be of very great value to every municipality in the world. We cannot say what system the Commission will advise the Imperial Government to adopt and recommend for the use of the British public, but I have received information from a gentleman closely identified with the commissioners and government sanitary works, and what he tells me appears to point to the bacterial system being recommended. This is a system which takes the raw sewage and passes it through an artificial filter, the contents of which are sown with live, friendly bacteria, which attract every minute atom of dirty fluid as it passes through the filter, and eat up, or otherwise totally destroy all the filth and poisonous ingredients the sewage contains without the aid of

chemicals or precipitants of any kind, and by so doing, abolish the sludge difficulty, because when the germs have done their duty, there are no solids left to remove. The printed reports and description my friend was kind enough to send me, are long and exhaustive, and would be difficult to understand, for readers that have not fully studied the subject of purifying sewage by microbes. On this ground I propose to condense this report to about one per cent., at the same time show how the bacterial system is operated, and how foul fluids are purified by that process.

It is probable that the Commissioners will recommend more than one system, for the sewage discharged from breweries, galvanizing works, sugar and grease factories, soap works, and dye-houses, all require a different method of treatment, but can all be treated by bacteria of one or other of the variety of classes. Different classes need handling by different processes, but there are three systems that purify sewage by bacteria, that appear able to treat any kind of sewage sent to them.

Adney's system, fully described on page 346 of the Canadian Engineer, dated April, 1898, uses a precipitant, and also adds nitrate of soda to the sewage to answer in place of aerating. Cameron uses a septic tank which the sewage must pass through and remain in for 24 hours, to allow the class of anaerobic bacteria to work on the dirty fluid, compelling fermentation, and breaking up and disintegrating the particles, and letting free the foul gases. The sewage is then aerated, which promptly kills the anaerobic germs, and the fluid passes into the bacteria filter to secure purification.

The third system is the one I propose to describe, as it has not been explained before in this paper, and the inventor claims that he can handle any kind of sewage (which I doubt); but the process may answer well, where the sewage is 80 per cent. domestic. The method is used at Crossness, treating the London, Eng., sewage, and a few smaller places. Bacteria are the only instruments used, and they are delicate creatures to handle; they easily succumb if they are overfed, or run short of air; and if the discharge from the filters is too rapid, they are washed away, and pass out with the effluent. The works and management of this kind of sewage purification should cost much less than works that have been erected before, with the intention of purifying sewage, but experience proves that, so far, the experimental plants are far more costly. On account of bacteria requiring regular and strict rules of dieting and aeration, and that sewage often varies two or more times each day, requiring more or less time to be given to the microbes to perform the work, a point which the green attendants cannot understand, causes the bacteria culture that has been carefully sown in the filters to soon become disabled, and scientific experts have to be called in to resow the filtrate with bacteria, and their charges for this work have been very extravagant; this makes the ratepayers shy of adopting a process that requires professionals to work it satisfactorily. This difficulty cannot last long, for to an intelligent person it must appear simple enough, and I am sure the workings of the bacteria culture sewage purification plants are as easy to learn as the majority of other plants, and if the system becomes common, there will be plenty of working men who will handle such works with as much, and probably more, efficiency than the scientific experts have been able to do thus far; when that time arrives, then bacteria-cultured filters will purify sewage cheaper than any other system. The sewage treated successfully at Crossness is a mixture of domestic and trade sewage, but it is not so difficult to treat as the Birmingham or Burton trade sewage.

It has been found that coke is best suited to form the filters at Crossness, probably because it leaves the largest space for fluids; and also that deep tanks will purify sewage equally as well as shallow ones, and do proportionally more work. The system of aerating the filtrates by giving them an alternate dose of sewage and air is adopted. The tanks are filled to within about one inch of the cokes' surface with raw sewage, which stands quiescent for about three hours to allow the friendly bacteria time to attack every particle of the sewage and extract the objectionable matter, after which the tank is slowly emptied, and as the fluid passes out of the coke the air is drawn in to fill the spaces. The filter is allowed to stand empty for about eight hours to allow time for the effluent to dribble out of the cells of the coke, and allow atmospheric air to pass in. It seems to me that the filters might be aerated both quicker and better by using the late George Waring's method of blowing air upwards through the coke filtrate with a fan, because eight hours would not then be wasted each filling to aerate the coke, and about two-thirds more work might be done by the same filter space; besides the face and air cells of the pieces of coke would secure a better cleaning. See description of Waring's system in March issue of the Canadian Engineer, page, 318, for 1899.

The amount of work that can be done by a sewage purification filter is estimated by the number of cubic feet of coke the filter contains; a good clean filter will hold over three gallons of sewage to each cubic foot of coke. Filters holding less in depth of coke than 3½ feet do not purify the sewage satisfactorily. At the Crossness works they have constructed filters holding a depth of 13 feet of coke; they appear to work all right, and there appears no reason why space might not be still more economized and filters made as deep as the seat and position of the sewage works will permit. Filter tanks may be constructed of brick or stone, concrete, or any material that cannot absorb moisture. There need be no limit to their superficial size, but one about 50 square yards can be handled best. At the bottom of each filter tank there is a series of suitable tile pipes spread all over, containing many small holes together with open joints, they are arranged somewhat similar to the trunk and branches of a large tree, the trunk end passes through the wall to a receiving culvert, having a valve attached so that the sewage can either be held in, or drawn from the tank, when necessary. Over this net work of pipes, selected and well cleaned coke, of a certain size throughout, is evenly and closely laid, up to the required depth, the surface being finished perfectly level. This done, the filter is ready to be sown with bacteria, which means getting all the air cells of the coke tenanted with families of bacteria germs; this usually takes one month, or about 50 fillings of sewage; the filters being filled, emptied and

aerated exactly the same as they are when working effectively; this assists the friendly bacteria to breed and multiply until their numbers are enough to destroy all injurious germs the foul sewage may contain, after which the effluent from the filters will be clean and fairly purified. The filters will, after being brought to this state of efficiency, continue so just so long as they secure proper and sufficient aeration or oxygen. To prevent the air cells of the coke getting choked with fibre, straw, wood, or any other indissoluble material, the sewage should be carefully sieved before it is allowed to pass on into the filters.

When these instructions are carried into effect, the effluent drawn from the filter is stated, by Messrs. Clowes and Houston, in their second report to the London County Council last year, to be better purified than the effluent discharged from any other sewage works that do not take advantage of the bacteria purification. Then if the effluent from the first filter is passed though a second one, it is brought to a purity of over 92 per cent., and the effluent that is discharged into the river is so well stocked with the cleansing germs that it continues its purification process until finally complete, which is said to be exactly opposite to the effluents discharged by works that only sieve the sewage, and use precipitants, because it is found that such effluents set up decomposition.

I might here say that the purified effluent from a sewage works using bacteria culture as a medium of purification is valuable for washing wool and dyeing soft goods; besides many other purposes, it is equal to spa water for business purposes and gardens. This system is not suitable for private hotels similar to the summer hotel at Pentanguishene, because before the sewage is turned on to a bacteria filter, it must be liquefied. The liquefaction process is done in the sewers themselves, in towns and cities, but it cannot be done where it only takes five minutes for the solids to travel from the water closet to the outfall, therefore the septic tank system that compels the sewage to remain one whole day in a tank, prior to passing to the filter, is the most suitable for such places to adopt. Should sewage be passed onto the filter unliquefied, the bacteria would be choked about the first dose, and the filter would be sick, and ruined, very similar to the artificial filter bed at Penetanguishene in 1897 and 1898. When a bacteria filter gets sick, and refuses to purify sewage, there is but one treatment to get it healthy, that is, to let it remain empty and receive plenty of aeration for a space of a week or a month, according to the seriousness of the damage done. If Waring's system of forcing air through the coke is used, probably one day might answer. Freely using a garden rake to loosen up the surface of the coke is also beneficial.

Sewage works cannot be worked on stereotyped principles, especially in manufacturing towns, because the quality of the sewage often changes several times daily. When it is very dense and foul, then the bacteria germs need more time to digest the matter, and probably double the amount of time for aeration. Where coke cannot be easily and cheaply bought, there is no reason why coal, slag, domestic cinders, stone, chips, burnt clay, or other substances that can resist chemicals and moisture may not be used; coal has properties far in advance of coke for filtering purposes, but a filter charged with coal would only hold about half the liquid sewage that a coke filter will hold, which gives the latter a preference, but all this is fully explained in previous articles in the Canadian Engineer.

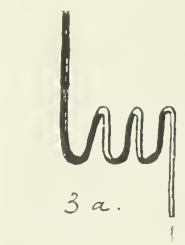
In summing up my remarks on this bacteria culture system of purifying sewage, I may say that it will be the cheapest and most efficient way of treating sewage yet invented, when properly worked on business principles, and a gigantic failure if not so operated. A very limited area of land will do for the plants, steam boilers or machinery will seldom be required, because if ten feet in depth between the level of the sewer invert and the surface of the water into which the effluent will have to be discharged, can be got, then the works will work all right by gravitation. There is no sludge to handle or get rid of, because the germs turn it all into gases or clear water. There are no costly precipitants to buy or mix by costly machinery; and we are insured to have an effluent that will not putrify and set up decomposition when mixed with fresh water. These are points worth noting, because in the past vast sums of money have been expended in sewage works, that have discharged a clarified effluent saturated with costly precipitants into the water courses, that have afterwards turned putrid, and done more damage to the body of fresh water into which it has become incorporated than the raw sewage would have done if the cost of treatment had been avoided.

HOT WATER CIRCULATION.*

BY R. W. KING, MECH. ENG., MEM. CAN. SOC. C.E.

(Continued from last issue).

In regard to the laying of the connecting pipes, they must be quite free from air-traps, or places where air can gather. To force water through a coil such as represented by Fig.3, it requires a head equal to the



3a. FIG. 3.

combined height of all the bends, with three bends one foot high it will require a head of over three feet to force water through, air being allowed to remain or gather in the coil. For this reason, perpendicular kinks or bends in horizontal flow or return pipes to a radiator, whose height would equal the diameter only of the pipe, would almost, if not quite, close the circulation to that radiator; since this imperfection would be noted, the chief danger lies in those bends or kinks that may close a radiator off by only a small per cent. of its efficiency.

*A paper read before the Toronto Engineers' Club.

A lack of heat in the room will likely be blamed by the fitter on anything but his own bad workmanship or design. Where bends or drops in a pipe are unavoidable, the air traps thus caused can be relieved and the pipe restored to its full circulating value by the running of air vents to above the water level or connecting to expansion tank, etc., etc., as the requirement of the particular case may demand.

This same principle applies to the circulation or flow of water in other pipes, such, for instance, as that unfortunate piece of engineering illustrated in the laying of the Toronto water works pipe across the bay, which, owing to the irregular shape of the bottom of the bay, is not likely to be laid perpendicularly in line. There is another difficulty here, namely, that every entrapped cubic foot of air, when under water, has a lifting power of about 62½ lbs. Now, by relieving these traps or upper bends (which must necessarily be in the shallower water), by some efficient device or plan, so no air of any serious extent can collect or gather in the pipe, the flow of the pipe will be restored to its normal capacity (which the mere holding of the pipe down by a weight of cribbing, stone or sand will not accomplish), and the desire of an iron pipe to tear itself apart in order to take a swim on the surface of the water entirely overcome.

In further support of this theory allow me to point out: First, that air or gases did accumulate in the waterworks pipe, since by no other possibility could an iron pipe float, and the fact of now holding it down by cribbing, etc., indicates that further accumulations of air are expected to reoccur and in fact probably already exist. Secondly, that where a pipe contains air it cannot contain water to its full capacity, and as previously noted, it matters not where the impediment to the freest possible circulation occurs, hence it follows that the capacity of the pipe, as a whole, to convey water, is reduced to the full extent or proportion of the air accumulation at any one point. Thirdly, a large accumulation of sand or other settlings was found in portions of this pipe. The presence of settlings in any portion of a pipe denotes that such pipe has not sufficient current passing through or sufficient drainage or head to prevent settlings from accumulating, and this condition can be brought about in the first place by an accumulation of air, as referred to, reducing the current or flow of water through the pipe, the more open parts of which then assume the duty of settling basins in the pipe itself. It should be the duty of the engineer in charge to examine the position carefully to discover if it is not possible to not only restore the flow impeded but also to increase it in other ways. This might avoid the immediate necessity of the expensive tunnel proposed by Manserge. It is not my wish that these remarks be taken as claiming to locate by one example the source from which all the difficulties and misfortunes occur, since there are other phases to this question of doubtful reputation leaving considerable choice in the matter; but I have referred to this in illustration, as being akin to my subject, which I have also desired to make as widely interesting as possible. The above shows one instance where civil engineering is allied to mechanical, the laws controlling the flow of water through pipes being the connecting link in this case. So the civil engineer, in designing such work, must also be a mechanical engineer. You thus see that though the boiler in a system may be correctly designed and efficient under one system of radiation, it may fail to accomplish the work expected in another, and that from no fault in the boiler itself. Also, that radiators may fail to heat the space assigned to them from defects in the boiler or in some other part of the system, as for instance the size or arrangement of the connecting piping, as will be afterwards described.

Thus it is seen that in seeking to determine the efficiency of a hot water boiler or radiator, or in fact any of the units of a system, as a whole, the individual unit in question must be treated apart from other units of the system. Further, in reference to the connecting pipes between boiler and radiators, it is important that they be correctly proportioned in size or area to the various parts of the radiation they have to supply. Since the motive power of the circulation is due to the height of the driving columns, multiplied by difference in their weight, it follows that on the different floors, different proportions in the area of the connecting pipes are required so as to distribute to the radiators on the different floors their proper share of circulating power. By estimating the average height of floors, one above the other, at even distances, we are at least within the mark in stating that in a three-story house with basement, the effective proportional area of connecting pipes per square foot of radiation should run so as to give an excess of effective proportional area, etc., for the lower floor of three to one of the upper floor. This may be put in more practical shape by proposing to determine from best general practice a common unit of proportional area per square foot of radiation, which may be used when once obtained in all cases for determining, according to the nature of the work, whether or not sufficient circulating area is provided—in the boiler itself; or in the radiators themselves; or in their connecting pipes individually. This unit will be used, as follows:

Radiators having been selected and placed for the different floors, the sizes of the pipes individually required will be determined by multiplying the square feet of radiating surface in the radiators by the unit, and then by three for the radiators on the ground floor, by two for the radiators on the middle floor, and by one for the radiators in the upper story. These sizes or areas will determine, by examination of their design, if the individual radiators have sufficient water-way in themselves, and the sum total of these areas will determine if there is sufficient water-way in the boiler itself.

I will note here that since a pipe of four square inches' area will convey more than double the water of a pipe of two square inches area, this difference should be taken into account and may be found tabulated in books of reference. I will also note that it is important that the boiler is placed (on this plan), so it may give an effective height to the circulating pipes in basement equal to the average stories in the house. A boiler, where the return pipes fall completely to the floor, and begin to heat immediately on rising therefrom will thereby utilize the full height of the basement for enforcing circulation, and its water way be of more proportional value than in one less effectively placed, for which due allowance must proportionally be made. In cases where the basement lacks sufficient height, the ground floor radiators are the ones most unfavorably affected. A lack

of circulating force to a radiator can be improved by piping to the top of a radiator as in No. 1.—instead of to the bottom, as in No. 2—and may help in some instances to acquire the necessary amount. I will close this portion of my subject by a few deductions that may be arrived at from the reasoning that has preceded.

In competitive boiler tests, in which it has been attempted to make all conditions, except the boilers, the same, the most efficient boiler may show the lowest average temperature at the point where the circulation leaves—and not the highest, as has been ignorantly supposed must always be the case. Boilers that compel the water to follow a tortuous course, in order to keep the same water as long as possible in contact with the heating surfaces, destroy the efficiency of those surfaces to absorb heat, impede the circulation, and are therefore of inferior and ignorant design. Radiators that compel the water to follow a tortuous course, so it may travel all through all of the loops in order to be as fully cooled as possible, though the effect may be to show the hottest water entering the radiator and the coldest when leaving it, as compared with other radiators, are wrong and inefficient in design inasmuch as it has been shown that that system as a whole will be the most efficient where flow and return or in fact all parts of the system are nearest to the same temperature. Such a radiator was attempted to be put on the market at a recent date, but failed, I believe, in accomplishing its object. The desired efficiency of a hot water heating plant as a whole cannot be insured simply by the purchase of a boiler or radiator of good design, which may be guaranteed of high efficiency when correctly installed. The correct installing of a hot water, or in fact any heating plant, involves engineering questions that the average man, calling himself a steam fitter or pipe fitter, as a rule, knows very little of; the employment of such a man in an engineering capacity is the direct cause of so many failures in such plants to do the duty expected of them. It is foolish economy to use too small connecting pipes to save first cost of apparatus; also in using less leads than the boiler is designed to supply, and plugging or reducing the unused holes intended for circulation.

Under some exceptional conditions it may be necessary to increase the area of circulation provided for general purposes, or discard the boiler if this is not possible. It is necessary for the man who takes up this work expecting to succeed (unless by accident), to acquaint himself with such principles as in part enumerated—but which owing to the limited scope of this paper cannot be here further enlarged upon. Having shown that in criticizing the efficiency of a hot water circulating plant, as a whole, it is necessary to independently handle the different units therein; we will now proceed to the latter part of this paper, namely, how to test the efficiency of a hot water boiler apart from its radiators and connections.

Most engineers are, in a way, familiar with the testing of steam boilers, but for hot water boilers I have not yet met with any method in use that will fill the requirement which is open to ordinary mortals to follow. I say ordinary mortals, since it is a custom in the higher schools of science and art, to so burden such investigations with algebraical formulae, logarithms, calculus, etc., combining so little practical information that ordinary mortals are excluded from following, or find life too short to take up the subject in that way.

In considering the task before us, we will find we have three measurements to accurately obtain, on which to base calculations as to the amount of heat units captured by the boiler; these are:

1st. The temperature, or in other words, the proportion of heat units in the water when it enters the boiler. 2nd. The temperature, or in other words the proportion of heat units in the water, when it leaves the boiler. 3rd. The rate or quantity of the flow of the water.

It is comparatively easy to obtain the first and second values, but not the third, because of the necessity of procuring an instrument delicate enough to measure the rate of flow correctly that can be put in a pipe without obstructing it, and so impeding the circulation with injurious results. There are ways proposed for measuring, or I would rather say estimating, the amount of water passing in a pipe without obstructing it, one of which only I will refer to in order to show the difficulties to be contended with.

In Fig. 3, let A. B. be a pipe with water flowing through it. At points A. and B. we tap in small pipes C. and D., and bring their other ends together, and turned upright, as at E. The head or force of the circulation will be represented by the difference in height of the water in the two columns at E. Having ascertained the head and the size of the orifice through which the water flows, the amount passing could be accurately calculated but for one thing, the allowance necessary to be made, scientifically called the coefficient, for the friction of the piping or in other words the impediment to theoretically free circulation. To obtain this correctly requires other tests and experiments of a complicated character; also the difference in height of the columns at E. being very small would have to be taken by miscroscopic or micrometer measurements. There is another trouble; the main circulating pipes will be found in the basement, so the ends E. would have to be extended a considerable height; this would necessitate note being taken of the temperature of the water in these columns, so any variation in weight thereby could be calculated. Furthermore, as during the test, the rates of temperature and flow will be continually changing, observations would have to be continually made; this applies also to the proposition to use an ordinary water meter could one of sufficient delicacy be found. When you consider in connection with this the mass of figures necessary to be made to obtain final results correctly, you will not wonder that the ordinary mortal referred to is discouraged and dismayed. Still the problem is before us, and the question is, if we can't make a frontal attack is there any way to get around? Every man has his own way of doing things, and without wishing to show any disrespect for the methods of others, to which if presented I shall only be too pleased to listen, I beg your kind indulgence while I explain what I think is one solution of the difficulty and afterwards invite discussion or criticism of it for mutual benefit and interest.

We have already shown how the efficiency of a boiler may be influenced by defects in the system. For the purpose of testing the efficiency of the boiler itself, I disconnect it from its system of radiation and treat it separately. It has already been explained that there are three measurements to be taken, and the complica-

tions that arise where the three measurements are unknown quantities are constantly varying at all times during the test. In my practical test, I endeavor to relieve this complication by making two out of the three measurements "known quantities," and constant at all times during the test, thus leaving practically only one measurement to be dealt with during the test, and proceed to explain briefly, as follows: To the boiler, Fig. 4, is attached flow and return pipes of the full capacity provided for in the boiler, running upwards and connected to an expansion tank in the ordinary manner. In the overflow of the expansion tank at T. is placed (in preference), a recording thermometer or an ordinary thermometer, as opportunity may offer. Opening into the return pipe is a small pipe, T2, carrying a known quantity of water per minute at a known temperature. With this our testing apparatus is complete. Let me first explain how the latter parts of this apparatus can be made. Roughly, I would propose an ordinary closet tank maintaining water by tap and float at a stated level; from this tank a pipe leads to the return pipe of the boiler, the discharge of which under the head of water in the closet tank has been measured and adjusted to suit requirements; but for more close or accurate work I have devised a special water meter, driven by clock work, that will not only accurately measure an even continuous flow, but also automatically record the same. For obtaining a constant known temperature, water from a tank of melting ice should be used, or an ordinary water service which will run a stream at constant temperature may answer as well, but to be exact and sure in this measurement a thermometer should also be placed at T2, so, should there be any variation in this temperature, it can be noted and allowed for, though complicating the calculations to some extent.

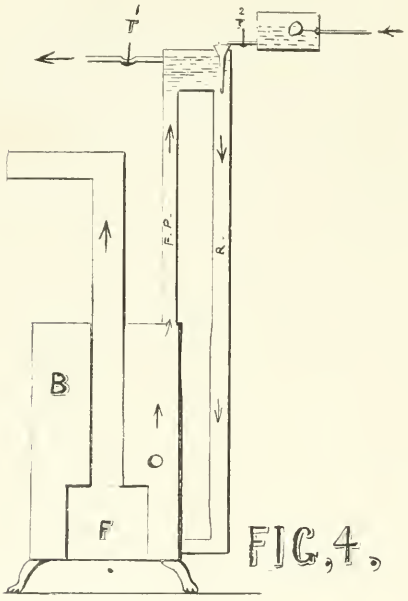


FIG. 4.

Now let me say a word on the thermometer and meter. I may be a crank on automatic machinery, possibly it is inherent laziness on my part, but instead of putting ordinary thermometers at the points indicated, and depending on taking their readings correctly (so I could swear to them), every five minutes or otherwise, during a 24-hour test, I want to put automatic recording thermometers there, of the Callendar pattern, that require no watching and will give results to a fraction of a degree and time, whose records can for evidence be photographed and reproduced in print free from the possibility of personal error. So also with the measurement of the flow, but to explain such instruments would take one or more papers, and so must be passed over for the present.

Having rigged my testing apparatus, we will proceed, as follows: The apparatus being empty of water, we will start our water meter, stopping it when the water gets to overflow, so we may know the first contents; at the finish of test the heat remaining in this water above the normal will be one of the quantities to consider and add to main results. Our apparatus and the boiler being now full, we will start the fire on a measured quantity of fuel and make a mark on the time record of the thermometer. On the water in expansion tank having acquired an ordinary working temperature, the time being automatically noted or otherwise, we start the water to circulate through the meter at a rate previously decided on as in proper proportion to the size of the apparatus, and allowing the party interested in the economy of the boiler to fire up to the best of his knowledge or ability. With automatic instruments our work is over until the completion of the test; the recording instrument being under lock and key, they cannot be tampered with. It being only necessary to insure further that the fireman is honest in regard to using no fuel but that measured out to him, so the quantity of fuel burned during the test may be determined in the usual manner.

At the close of tests we consult the records which are then the records of what has been performed. Our report, therefore, will show, backed by the records and evidence referred to, that by the consumption of a certain amount of fuel during a stated time, in a hot water circulating boiler, we have raised the temperature of a stated quantity of water a certain number of degrees, the average being determined from the temperature curves that the thermometers have recorded, thus giving simple data for obtaining both the efficiency and power of the boiler. The test would also show clearly at what part of the firing the best results were being obtained and so be a guide in this respect and in determining the best proportions for the fire surface, etc.

From the data recorded, as above, it is a comparatively simple matter to determine the number of British Thermal Units that have been abstracted from a stated quantity of fuel during a certain time for comparison with other absolute tests that may have been elsewhere made of other boilers, so giving their relative efficiency and power. Also by reducing the values to what they would be in steam evaporation from and at 212° F., the efficiency and power of a hot water boiler is made comparable with that of a steam boiler. This may seem to be getting into complicated calculations, which we desired to avoid, but that depends, like the test itself, on how you take it, whether by frontal attack or by getting round—for instance, if you ask a college professor for a rule for determining these values, especially as regards the steam comparisons, if he is

unkind at the time he may present you with something like this, which he says has been founded on experiments, and is a fairly accurate guide for a frontal attack:

$$\log. p. = A - \frac{B}{T} - \frac{C}{T^4}$$

where A = 6.1007
log. B = 3.43642
log. C = 5.59873
P. = pressure
T = temperature

But if he is kindly disposed at the time he may tell you that for his part he usually gets around it by consulting a book of tables to determine these values, where the whole thing is figured out for you in a reliable manner.

IMPORTED IMPUDENCE.

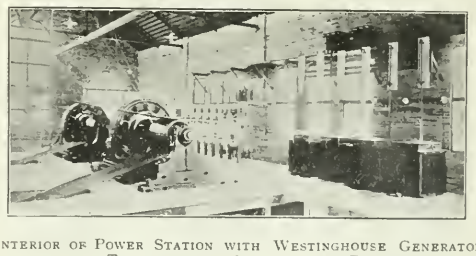
The Ontario Mining Protective Association has published a pamphlet on the Ontario Mines Act, which though written wholly in the interest of the Canadian Copper Co., has some points of interest for Canadian citizens. The front cover sets forth that "Ontario mining men protest against confiscation of vested rights without compensation; menace to the investments of capital; its effect upon the nickel and copper industries of Ontario. Mr. Clergue answered, and his ignorance of metallurgy exposed." This is very comprehensive, and one looks to derive great benefit from so intellectual and philanthropical a publication. The further facts that it is "cauld kail," from the Canadian Mining Review, and that it has been "het again," and published by the authority of the Council of the Ontario Mining Protective Association, are set forth. This last fact is of moment, because when receiving the pamphlet, we observed that it had come free through the mails, and that the wrapper bore the imprint of the Dominion House of Commons, and naturally believed the pamphlet to be a reprinted speech duly made in the House by the hon. member or members sitting for the Canadian Copper Co. It must be that a mistake was made by someone, and the O.M.P.A. printed matter has been sent out by an innocent member, instead of his own more eloquent and truthful discourse upon binder twine and ballot boxes. It seems hardly believable that a member of the Dominion House who represented anything but a corporation would have the temerity to use the franking privilege of the House to circulate a publication with the chapter "Ontario Mines Act; its unconstitutionality." Such an act is not only a fraud upon the public but it is a grave impropriety and an outrage upon the dignity of the province of Ontario. If the acts of the Ontario Government are unconstitutional, let the matter be discussed in the House, if necessary, and the Governor-General-in-Council may disallow the Act. But that the Tooley street tailors or the O.M.P.A. should pronounce privately upon the Act and employ the machinery of the Dominion Government to promulgate their findings is most grossly impertinent.

The employees of the Canada Switch and Spring Co., Montreal, held a ball, April 23rd, at Bout de l'Isle, about 250 guests being present. It was under the direction of J. Juteon, president; J. Diotte, secretary; R. Kelly and R. Cox, floor managers. The foremen of the different departments, Geo. P. Curtain, J. Hodgkiss and John Smith, were present.

METROPOLITAN RAILWAY, TORONTO.

A new power plant has been constructed by the Metropolitan Ry. Co., Toronto, and the length of its railroad has been more than doubled. The track previously extended from Yonge street, North Toronto, to Richmond Hill, a distance of 14 miles, with the power station at Deer Park. The tracks have now been extended from Richmond Hill to Newmarket, 30 miles from Toronto. The old power station has been done away with and a new one built at Bond's Lake, 18 miles from North Toronto and 12 miles from Newmarket, the present terminus of the line. There is also a sub-station, with rotary converters and transformers, at York Mills, 4½ miles from North Toronto. The railroad connects at North Toronto with all the tramway lines of the city of Toronto, and takes a northerly course in a straight line through the villages of Lansing, Glen Grove, Newton Brook, Thornhill, Richmond Hill and Elgin Mills to Newmarket. The track is laid in a very substantial manner with 70 lb. "T" rails, bonded, having the regular railway gauge of 4 feet 8½ inches, as it is intended to connect with the Canadian Pacific Railroad at North Toronto for the interchange of traffic. A Baldwin-Westinghouse electric locomotive will haul freight cars from the Canadian Pacific railroad to and from all stations on the Metropolitan Railway Company's system. At present the district through which this railway passes is served by the Grand Trunk railway only. The railroad ascends gradually from North Toronto for a distance of 22 miles to the summit of the divide or water-shed, which is between Aurora and Bond's Lake, reaching a height of 1,400 feet above the level of the lake. From this point there is a gradual descent to Newmarket. The line follows a comparatively straight course, but there are several long grades, the steepest of which is 8 per cent.

The contract for the building of the new power plant and the additions to the line was granted to the Imperial Lumber Company, Ltd., Toronto, which employed the Westinghouse Electric and Mnfg. Co. to supply the electrical plant and railway equipment. This contract comprised a new generating station and sub-station equipment, also motors for freight and passenger rolling stock and an electric locomotive.



Interior of Power Station with Westinghouse Generators and Transformers. Metropolitan Railway Company, Toronto, Canada.

The new power house is at Bond's Lake, 18 miles from North Toronto. The power house has been erected by the side of the lake, from which water for the boilers and condensers is readily obtained. The building is of brick with steel truss roof. One end of the building serves for the boiler house, the smokestack abutting upon the western wall. Adjoining the boiler house and extending 10 feet beyond it on either side, is the engine and dynamo room, containing two cross-compound condensing steam engines, belted to two 275 k.w. Westinghouse A.C., D.C. 60-cycle, three-phase generators, running at 600 r.p.m., wound for 400 volts alternating current, and for 570 volts direct current. An interior view of the power station is shown in Fig. 1. The direct current supplies the local feeders, the alternating current being carried to the transformers and transmitted to the rotary converters in the sub-station at York Mills. The generators are designed to deliver and utilize their full rated capacity at the D.C. end or at the A.C. end, or the loads to automatically divide in any proportion at either end and to generate electrical energy to their rated capacities as may be called for by the varying loads passing over the railway. Whether the demand for current be from local point near the

power house requiring ordinary direct current voltage to the trolley line, or an extra demand arises for the high voltage alternating current to the sub-station line, the generators will deliver automatically their full rated capacity in accordance with the varying demands from these two sources.

The shunt and series field coils of the generator are wound separately, having ventilating spaces between each other and the pole pieces. The generators have three bearings which are self-aligning and self-oiling. The armature cores are built up of laminated steel manufactured specially for the Westinghouse Company, with slots on the periphery arranged for the reception of coils. The closed coil winding consists of rectangular copper bars, shaped and insulated before being placed in the core. Ventilating spaces are left in the core, and at each end between the core and winding. Hard rolled copper bars insulated with mica are used for the commutator, which is mounted on the armature spider; the collector rings are connected to the same winding and placed upon the opposite end of the armature. The brush holders, both for the commutator and the A.C. collectors, are separated by lugs upon the bearings. Copper brushes are used for the collectors, and carbon in improved holders for the commutators, the latter holders are capable of being shifted by means of a wheel operating a gear in a worm. The generators are guaranteed to have an overload capacity of 15 per cent. for twenty-four hours with a rise in temperature not to exceed 50 degrees C. above the surrounding air, and to carry 40 per cent. overload for two hours, or 50 per cent. overload for one-half hour without injurious heating and sparking.

Two exciters of the standard Westinghouse type have been belted to the ends of the generator armature shafts; they are of the four pole type, compound wound, 125 volts, operating at 1,600 r.p.m., and have the same general characteristics as the generators above described, but without the A.C. collector rings. The A.C. current from the generators is carried to four 125 k.w. Westinghouse transformers of the self-cooling oil-insulated type, which are placed near the end wall of the power house. They are wound for 400 volts primary and 15,000 volts secondary, two of them being connected with each generator. The high tension current is conveyed by overhead lines to the sub-station at York Mills. The marble switchboard consists of eight panels, and occupies the end of the power house. The switchboard is arranged for the multiple arcing of the A.C. ends of

Two 200 k.w. Westinghouse Rotaries, Transformers and Switchboard at York Mills Sub-station, Metropolitan Railway Co., Toronto, Can.

the two generators, and also for the multiple arcing of the D.C. ends of the two double end generators, together with the two generators formerly used in the discarded power house of the company, which are to be rewound for present service. The two panels respectively control the A.C. ends of the two A.C.-D.C. generators. Four additional panels are provided for the D.C. end of the two A.C. D.C. generators, and for the two older generators.

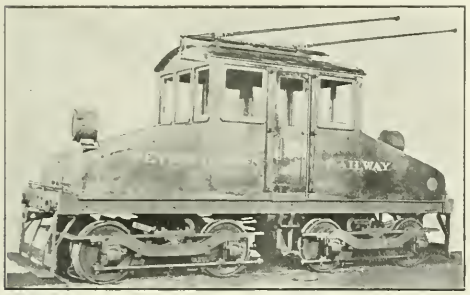
The equipment of the sub-station at York Mills consists of four 100 k.w. Westinghouse transformers, wound for 13,000 volts primary and 400 volts secondary, two for use with each rotary. The current is carried from the transformers to two 200 k.w. Westinghouse rotary converters seen in Fig. 2, which transform the 60 cycle, three-phase alternating current into a 570 volt direct current for local distribution. The rotary converters and the transformers are designed to carry an overload of 25 per cent. for twenty-four hours without a rise of more than 60 degrees C., and to carry a 50 per cent. overload for two hours, without injurious heating or sparking. The generators at the central station and the rotaries at the sub-station are constructed on similar lines, having inwardly projecting pole pieces made of soft laminated steel, so proportioned as to permit the immense variations of load without shifting the point of commutation, thus making the shifting of brushes unnecessary. The pole pieces are cast into an iron yoke divided horizontally, the lower half with two bearings cast in one piece to ensure perfect alignment.

It is projected to make further extensions to the Metropolitan Railway Company's lines, one 13 miles in length is already under construction, extending from Aurora westwards. The plans of the company anticipate a time when a large central power station will be necessary, and the present generators will then serve for rotary converters. This can be effected by removing the pulley and placing in its stead a starting motor, or bringing them up to speed by any other extraneous means, or as direct current motors. The generators are equally serviceable for the supply of energy for incandescent or arc lighting, and for power for polyphase induction or synchronous motors. The rotary converters at present are started by an induction motor, placed on the shaft of the rotary and supported on a bracket. Upon the proper speed being reached as indicated by the synchronizer on the switchboard, the rotary's switch is thrown, and it maintains its own speed, the starting motor being then out of circuit. These generators at the central station, and the rotary converters at the sub-station operate in multiple, are at both ends, and the generators are arranged to operate in multiple with the older D.C. machines previously used on the railway company's line, when the latter shall be compound wound. The transformers are constructed with the core consisting of laminated steel of the highest magnetic quality. Both primary and secondary windings are divided into several flat coils insulated separately. Loops are brought out from the low potential side so that three voltages may be secured on the D.C. end of the rotaries as desired. The terminals are placed on marble plates, the high potential at one end and the low potential at the other, the connecting wires pass through the top of the case in insulating bushings. The sub-station switchboard consists of five panels, two A.C. rotary transformer panels, two D.C. rotary transformer panels, and one double feeder panel.

Ample protection against electrical storms has been provided by equipping the station with three Wurts lighting arrester outfits for 15,000 volts for the A.C. line and a Wurts railway tank lightning arrester outfit for the D.C. side. The Westinghouse lightning arresters have a two-fold function, providing a path to the earth offering the least possible resistance to the passage of static discharges, and avoiding any interruption of service whether at the moment of those discharges, or at other times. The apparatus connected to the high potential alternating circuits is protected by a combination, consisting of a number of Wurts non-arcing metal lightning arresters in porcelain cases placed between the terminals of a bank of choke coils and the earth. Lightning or static discharges being of a highly oscillating character, the coils have a greater retarding effect, and cause the discharges to prefer the easier course to the earth through the lightning arresters. Six such choke coils interpose an effective resistance to the lightning discharges, but have no appreciable effect on the generator current. A good ground for the lightning arresters has been provided by a plate of No. 16 tinned copper, placed in a pond, which is connected by an almost straight wire with the arresters. One individual arrester has been connected with each direct current panel of the switchboard. The station apparatus is further protected by a railway tank arrester, consisting of a bank of twelve coils, leading to plates in a tank through which in time of storm a stream of water flows. The coils are connected in series with the D.C. bus bars, and are so installed that except in time of atmospheric electrical disturbances they are not connected to the bank.

The Metropolitan Railway Company has added to its rolling stock some freight cars, some of them of a heavier kind, equipped with four 38 B Westinghouse motors, also smaller ones with a double 49 Westinghouse equipment. It has also added single truck passenger cars, carrying two 38 h.p. West

inghouse equipments, and also some 45 feet double truck passenger cars with quadruple 38-B motors are designed upon similar lines only differing in capacity. In both cases the field is of four soft laminated steel pole pieces, cast into a steel yoke divided horizontally, the two halves hinged together on the side opposite the axle. The field coils, armature, commutator and brushes are completely enclosed by the two field castings, and thus absolutely protected from dampness and dust. A large opening, protected by a spring cover, is provided in the upper casting over the commutator to give ready access to that part and to the brush holders. The field coils are wound on a form and thoroughly insulated, one being placed over each pole piece, and held in place by a brass plate bolted to the yoke. The armature is of the "drum" type, of laminated soft steel with liberal air passages, the ventilated winding giving excellent



Baldwin-Westinghouse Electric Locomotive, Weighing 57,000 lbs. Metropolitan Railway Co., Toronto, Can.

ventilation. The winding is of machine wound coils insulated and slipped into slots in the core. The commutator is of hard drawn copper segments insulated with mica, and of such depth as to allow ample clearance for wear. Steel gears and pinions are used, enclosed by a tight projecting case, supported by its own bearings at one end, and the field casting at the other. The controllers are of the Westinghouse company's standard construction, of ample capacity to operate the motors at their full capacity. Resistances are made of strips of sheet iron insulated at each turn by mica and indestructible from heat. The Metropolitan Railway Company is building up a considerable freight and express business, which it intends to increase in the near future, and for this purpose has provided the electrically propelled freight cars mentioned above. These cars are engaged in carrying milk and farm produce to the city of Toronto, and general merchandise to the villages upon the road. The coal used at the central generating station has hitherto been transhipped at North Toronto into smaller cars, and hauled to the generating station by the trolley cars. The Metropolitan Railway Co. has now added to their stock a Baldwin-Westinghouse electric locomotive, which in the future will haul railway cars direct from the lines of the Canadian Pacific to all stations upon their system. By this means the cost of transhipment will be avoided, and farmers will be able to load their produce upon railway cars, and have it conveyed without transhipment to any point in the United States. The Baldwin-Westinghouse electric locomotive shown in Fig. 3 has driving wheels 33 inches in diameter, and weighs 57,000 pounds. It is equipped with four 50 h.p. Westinghouse 38-B motors, similar to those already mentioned. A complete Westinghouse air brake equipment has been provided for the locomotive, including a combined pump and motor with capacity for five cars; and in addition an efficient hand brake to all wheels. The locomotive is designed to run at a speed upon the level of 35 miles an hour, hauling cars with an aggregate weight of 60 tons.

The plants of the Welland Vale Co.'s works and the Canada Motor and Cycle Co.'s works at St. Catharines, Ont., were burned, May 16th. The fire started in the hardening department of the cycle works. This throws 500 men out of work. The Welland Vale Co.'s loss will be about $200,000, with insurance of about $85,000. The Canada Cycle and Motor Co. had an insurance of $40,000 on the machinery and $65,000 on its stock.

AN ABSOLUTE DETERMINATION OF THE THERMAL CONDUCTIVITY OF METALS.

(Continued from last issue).

THERMO-ELECTRIC EFFECTS

In the original experiments performed by Mr. King and also in the preliminaries of these experiments an ordinary brass contact key was used in the galvanometer circuit, and also mercury cups were used for terminals of the potential wires. The readings were found to be inconsistent when the current was reversed, and the cause was attributed to the different metals in the key and mercury cups, which when the temperature varied about them caused thermo-electric effects. To remedy this the mercury cups and contact key were replaced by copper binding posts and a copper key and the results then obtained were very satisfactory. The key was made of a piece of pure copper on a wooden base and connections were made to it by means of copper screws and washers.

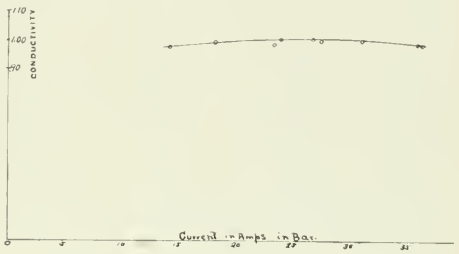


Fig. 4

METHOD OF TAKING OBSERVATIONS.

The balance points on the potentiometer with the terminal "g" of the galvanometer successively in the binding posts 1, 2, 3, 4, were obtained with the current in either direction. From these observations the resistance of the bar was obtained in terms of the .001 ohm standard. The current was measured by using a Weston milli-voltmeter to obtain the fall of potential across the terminals of the .001 standard. In this way the current could be very accurately determined, provided that the milli-voltmeter was accurately calibrated. This was done in the following manner and a curve drawn showing at a glance what should be added to or what should be subtracted from the reading of the milli-voltmeter.

CALIBRATION OF MILLI-VOLTMETER.

The milli-voltmeter did not read directly in milli-volts, five divisions on the scale corresponding to one milli-volt, hence all readings had to be divided by five after having been corrected.

The milli-voltmeter M was connected in series with standard ten *ohm* resistance R, a resistance box B, and a storage cell S. CC is a standard Clark cell of voltage = 1.4342 at 15°C. K is the contact key, G a galvanometer, P a potentiometer, and M the milli-voltmeter to be calibrated. A storage cell was connected to the terminals of the potentiometer, and a standard Clark cell was also arranged, the negative pole to the same terminal as the negative pole of the storage battery, while the positive pole passed through a contact key and galvanometer to the potentiometer movable contact. In this way the potentiometer could be standardized, the volts obtained at any time

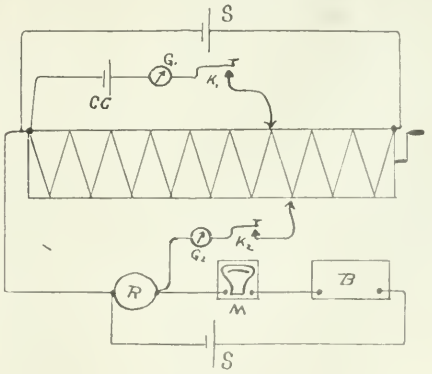

Fig. 5

[1] A paper read before the Applied Science Society of McGill University, session 1899-1900.

by adjusting the movable contact to balance the galvanometer G. From this arrangement the fall of potential across the standard ten *ohm* resistance could be found very accurately, and this would give the current flowing in the milli-voltmeter. The corresponding deflection was then observed. Readings were taken in this way for every ten divisions of the milli-voltmeter. These readings are given in columns 1 and 2 on page 14. The resistance of the milli-voltmeter was then measured and found to be .847 *ohm* at 18.°5 C. From this resistance and the several values of the current flowing the potential required to produce this current through the milli-voltmeter was calculated. The difference between this calculated potential and the potential indicated by the milli-voltmeter is given in column 4. These differences were then plotted and a curve drawn showing at a glance what was to be subtracted or added to the readings of the milli-voltmeter. A copy of this curve is given with this paper, fig. VI. Readings:

Milli-voltmeter reading.	Current flowing through M.	Calculated volts.	Differences in divisions.

OBSERVATIONS AND RESULTS.

Saturday, Aug. 5th, 1899.

Temperature of bath.	Current in circuit.	Direction of current.	Potentiometer Readings, No. 1.	No. 2.	No. 3.	No. 4.
18.8	2.97 amps.	—	9.484	53.841	63.042	99.162
18.8	2.97 "	×	8.457	53.828	63.015	99.158
18 8	18.25 "	—	9 385	54.345	63.449	99.164
18.85	18.25 "	×	9.397	54.339	63.434	99.165
19.0	36.18 "	—	9.090	55.778	64.564	99.194
19.0	36.18 "	×	9.098	55.772	64 566	99.195

From the above observations the following was calculated:

Resistance.	Current.	Bath Temp.	Mean Cu. Temp.	Mean Rise.	Max. Rise.
0012355	0 amps	19.° Cu	—	—	—
0012362	2.97 "	19.0 "	—	—	—
0012665	18.25 "	19 03 "	25 26	6.23	9 34
.0013571	36.18 "	19.20 "	44.02	24 82	37 23

$$Cu_a = 25.26 \therefore \frac{dCu}{dx} = 3.968$$

$$Cu_b = 44.02 \therefore " = 15\ 80$$

$$q_a = 18.25 \times .0012357 = .2058$$

$$q_b = 36.18 \times .0012364 = .8092$$

$$K_a = \frac{.2058}{3.968 \times 5205} = .996$$

$$K_b = \frac{.8092}{15.80 \times 5205} = .985$$

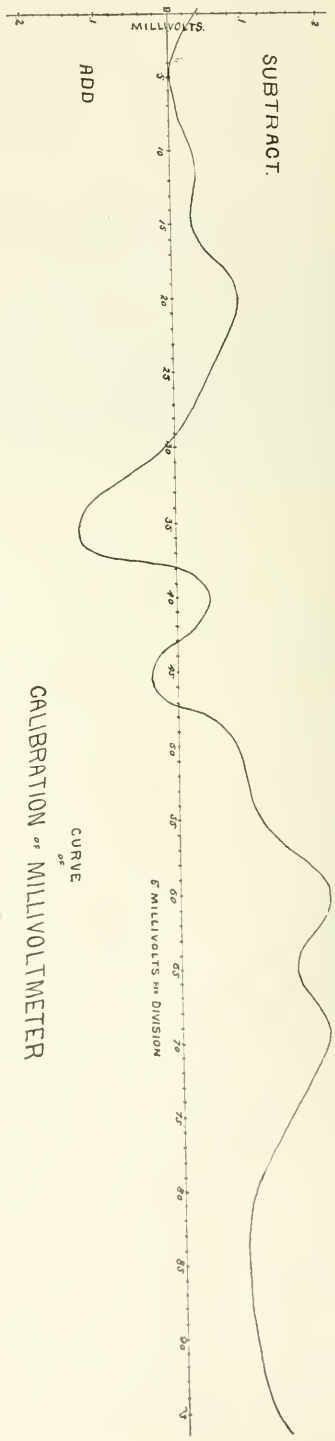
These results are very consistent, as may be seen in accompanying curve diagram of results, Fig IV

The following are the results obtained at different times during the summer, the observations being omitted for space

Date	Current.	K
Aug. 5th	18 25 amps.	996
" "	36.18 "	985
" 11th	14 59 "	1 008
" "	26 84 "	1.007
" "	36 20 "	.987
" 19th	23.5 "	970
" 21st	23 3 "	.985
Sept 9th	31 2 "	995
"	36 8 "	965

The above results have been plotted to scale on section paper and are given with this paper.

A number of other results were obtained before the apparatus was all in good working order, some of which compare favorably with those given. The experiments could not be finished during the summer on account of lack of time, and it is proposed to continue them at a later date.



On September 8th, 1899, another set of observations was taken to compare with the foregoing as a confirmatory test, with the following results:

R_0 was found to be = .0011446 at zero current, as compared with .0011445 " the mean R_0 (see page 14).

At a current of 31.2 amps. Cu. was found to be = 35.61
and Cu. max. = 27.30
also q = .600
Hence K = .997

At a current of 36.9 amps Cu. was found to be = 43.85
and Cu. max. = 39.67
also q = .837
Hence K = .960

The above results agree very well with those already given, as shown by the accompanying curve (Fig. IV.). From the foregoing data we see that the critical current is about 27 amperes, for which value of the current we find the conductivity to be 1.007. In other words, if in a cube of copper of unit dimensions (1 cm.) there exists a difference of temperature of 1° C. between two opposite faces, there will be a flow of 1.007 calories of heat from one surface to the other, in unit time, at a temperature of 33°C.

GAS ENGINE DIMENSIONS.

Prospective gas engine purchasers have always been at a serious disadvantage when deciding between different designs offered them, from the fact that manufacturers, heretofore, have not listed the size of cylinders for the different ratings of horse-power. We reproduce the dimension list of the "Model" gas and gasoline engines, built by the Goldie and McCulloch Co., Ltd., Galt, Ont., which is the first company to take this decided step, which certainly appears to be in the right direction. If it is necessary to know steam engine sizes, in order to make an intelligent choice it is evident that the same rule should apply to gas engine practice:

Actual H.P.	Speed Rev. per min.	Size of Cylinder.	Floor Space Over All	Driving Pulley	Belt
		Dia. Stroke.		Dia. Width.	
1½ to 2	250 to 350	5 in.— 6 in.	35 in. x 43 in.	10 in. x 8½ in.	4 in.
2¼ to 3	240 to 325	5½ in.— 7 in.	35½ in. x 45 in.	10 in. x 8½ in.	4 in.
3 to 4	230 to 315	6¼ in.— 8 in.	36 in. x 50 in.	12 in. x 9 in.	4½ in.
4½ to 6	225 to 300	7 in.— 9 in.	39½ in. x 54 in.	12 in. x 10 in.	5 in.
6½ to 8	215 to 265	7¾ in.—10 in.	44 in. x 66 in.	14 in. x 11 in.	5½ in.
8½ to 10	205 to 240	8¾ in.—11 in.	53 in. x 76 in.	16 in. x 12½ in.	6 in.
10½ to 12	200 to 230	9¼ in.—12 in.	53 in. x 80 in.	18 in. x 14 in.	7 in.
13 to 15	195 to 225	10 in.—13 in.	60 in. x 84 in.	20 in. x 16½ in.	8 in.
16 to 20	170 to 210	10¾ in.—15 in.	60 in. x 90 in.	26 in. x 16½ in.	8 in.

HEAVY RAILS BADLY MADE.

There was an interesting discussion at the annual convention of the American Railway Engineering and Maintenance of Way Association held in Chicago a couple of weeks ago on the rail question. It was in connection with the report of the committee on rails, and was precipitated by Mr. Peterson, chief engineer of the Canadian Pacific.

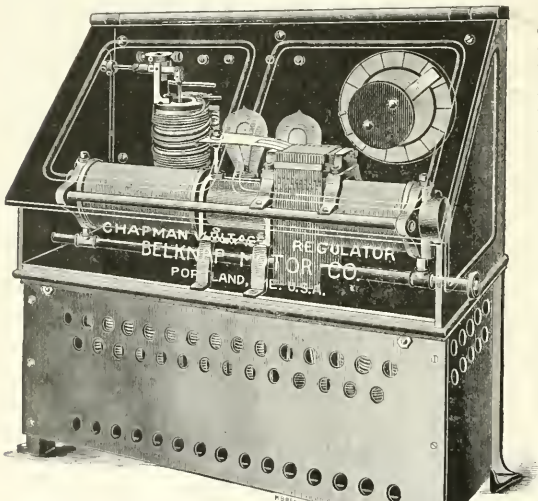
Mr. Peterson asked Captain Hunt, who is the authority on steel rails, why it was that the railways did not get as good rails as they did in the olden days. There are rails at present, 56-pound rails, in use in the Canadian Pacific laid in 1875, and which have been subjected to the heaviest use, which are better rails than the 80-pound rails the road can buy now-a-days. Captain Hunt replied that the modern rail did not give as good results as obtained from the original steel rail, or that made in the earlier days of the Bessemer manufacture, because the same care was not expended in its construction. Rail manufacturers found out that Bessemer steel could be heated to a much higher degree than was supposed. Then came competition. Railways quit ordering rails when hard times came. Good times came again with a desire to cheapen production. The result was that rails were made cheaper by making them faster and with less care. As the weight of the rail had been increased, so the effect of the heat under which the rail was worked was increased, resulting in a coarser grained steel, which cannot stand abrasion as did the old closely rolled rail. Capt. Hunt expressed the opinion that if the railways kept on increasing the size of the section they would presently have a rail head that is in character no better than the bloom from which the original rail was rolled. That is, the steel in the new heavy section rail will be no higher grade than that from which the old rail was rolled.

Discussing this feature the report of the committee stated: "It may not be out of place to call attention to the fact that many well meaning efforts at reform have been in vain, on account of the very radical position taken by some of the persons connected therewith. Therefore, if any of us incline to extreme views in such matters as high carbon or low carbon, let us find at least some common ground on which we can take a stand, and then we shall make headway, possibly slowly, but surely. If we agree on uniform sections for all our lines, we will eventually save for our companies, and possibly, in addition, increase the profits of the rail manufacturers, about which so much talk has been heard in Pittsburg recently. Let us agree on one other thing—that the mechanical treatment in rolling and the temperature at which the rail is finished is of the greatest importance—then insist on the mills making an improvement in this regard. If this association can agree on a specification for the manufacture of rail, which may not be perfect, but which will be a step in advance of what we are doing, have it approved by our companies, and accepted by the rail manufacturers, decided progress will have been accomplished.

THE CHAPMAN VOLTAGE REGULATORS AT ARMOUR CO.'S PLANT IN CHICAGO.

Each regulator consists of three essential parts, viz., a resistance to be inserted or removed from the field circuit of the generator to be regulated, a working solenoid to do the work of inserting and removing the resistance step by step from the circuit, and an auxiliary relay solenoid to determine the movement of the working solenoid. The resistance is made of German silver coils, units of the enamel resistance type or carbon. Ample carrying capacity is, it is claimed, provided so the resistance will not heat to any extent. This resistance is connected to a series of copper segments placed in a horizontal row, and having a contact slider arranged to move over their surface. This contact slider is operated by being mechanically connected to the moving core of the working solenoid. The working solenoid consists of two differentially wound coils placed on a brass tube, one at each end of the tube. The middle portion of the tube is left vacant. Inside of the tube is fitted an iron plunger, somewhat shorter than the distance through the two coils. At the centre of the plunger a rod is attached which passes out through a longitudinal slot cut in the vacant portion of the tube. The contact slider above described is attached to this rod and so moves with it and the plunger. In order to prevent too quick a movement of the plunger a simple retarding device is used. The iron plunger is hollow and the rod in its centre has a valve which can be closed and opened by turning a knob on the end to which the contact slider is fastened. The brass tube is closed at its end and completely filled with oil. The movements of the plunger towards either end can take place only as it displaces the oil and causes it to move through the hollow plunger. The rapidity of the movement can be very

finely adjusted by means of the valve above described. The force tending to move the iron plunger depends on the balancing of oppositely wound coils against each other and this balancing is determined by the action of the small auxiliary solenoid, whose only work is to cause one or another of two platinum pointed screws to make contact with the brass lever supporting its core. Contact with one screw causes perfect neutralization of the differential coil at one end of the working solenoid, and so disturbs the balance and causes the plunger to move toward the other coil. And contact with the other screw causes neutralization of the coil at the other and a movement in the opposite direction. The small solenoid may be wound to suit a variety of purposes, any one of which may be required in fulfilling the demands of station regulation. It may be wound with a simply fine winding to be connected as a shunt across the lines to be regulated, and in this case it will secure constant potential regulation at the point of attachment to the line. Or secondly, it may be wound with a fine wire as before, and also with a coarse winding. The fine winding connected as a shunt to the line,



Balknap Automatic Voltage Regulator.

and the coarse winding in series with the line. In this case it will regulate for constant potential at some distant point on the line which may be pre-determined by the setting of an adjustable compounding switch provided as a part of the regulator. Or, thirdly, the small solenoid may be wound with a single coarse wire placed in series with the line, in this latter case it will secure regulation for constant current in the lines. But whatever be the nature of the regulation the small solenoid will perform its duties with an accuracy as close as 1 per cent. above or below the normal, and is adapted to either direct or alternating currents. Alternating currents are claimed to be especially capable of close regulation by this instrument as the slight jar incident to its flow through the small solenoid almost entirely eliminate the element of friction at the pivots of the lever supporting the core, and it will easily recognize a change of half of a volt on a 110 volt circuit.

The Armour Co.'s plant at Chicago, which has just been started, is considered one of the largest in the world. It has a most expensive switchboard, and three No. 1 Belknap automatic voltage regulators on the front.

C. H. Wellman, of the Wellman Seaver Engineering Co., Cleveland, U.S., with Mrs. Wellman has gone to Europe. Mr. Wellman is chief engineer of the company; and the occasion of his departure was made the occasion of a most friendly demonstration on the part of the company's employees towards its chief engineer.

FIRES OF THE MONTH.

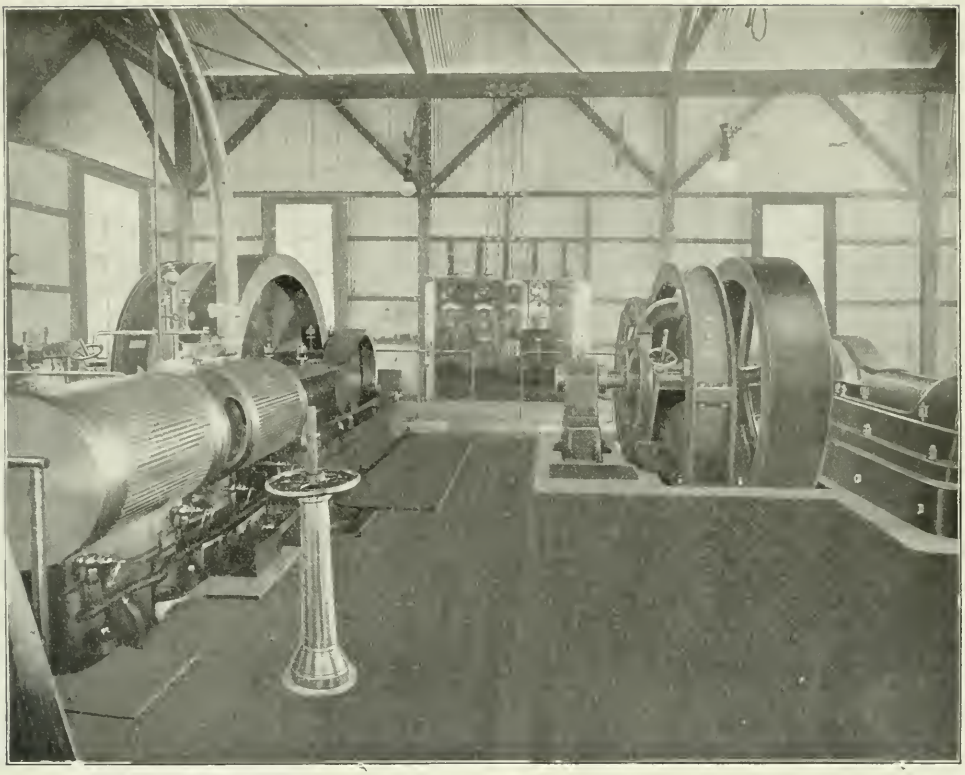
May 11th. Steamer "Marie-Louise," owned by J. Parkin, Lindsay, Ont.; damages, $3,500; insurance, $1,000.——May 16th. The Welland-Vale Mnfg. Co.'s works, St. Catharines, Ont.; damages, $200,000; insurance, $85,000; the Canada Cycle and Motor Co.'s plant, St. Catharines; damages about $50,000; fully insured.——May 16th. The pumping plant of the Charlottetown, P.E.I., waterworks.——May 16th. Steamer "Paul Smith," owned by R. Bickerdike, burned in the locks at Lachine, Que.——May 19th. Northern Elevator Co.'s elevator at Oakville, Man.——May 24th. Angus Plewes' flour mill at Markdale, Ont.; loss about $10,000.—— May 27th. Tellier, Rothwell & Co., chemical manufacturers, St. Dezier street, Montreal; damages, $30,000; fully insured.——May 30th J. C. Wilson & Co.'s paper mill, St. Jerome, Que.; damages, $10,000; fully insured; a new mill to cost $100,000 will be at once built.

EXPLORING NEW ONTARIO.

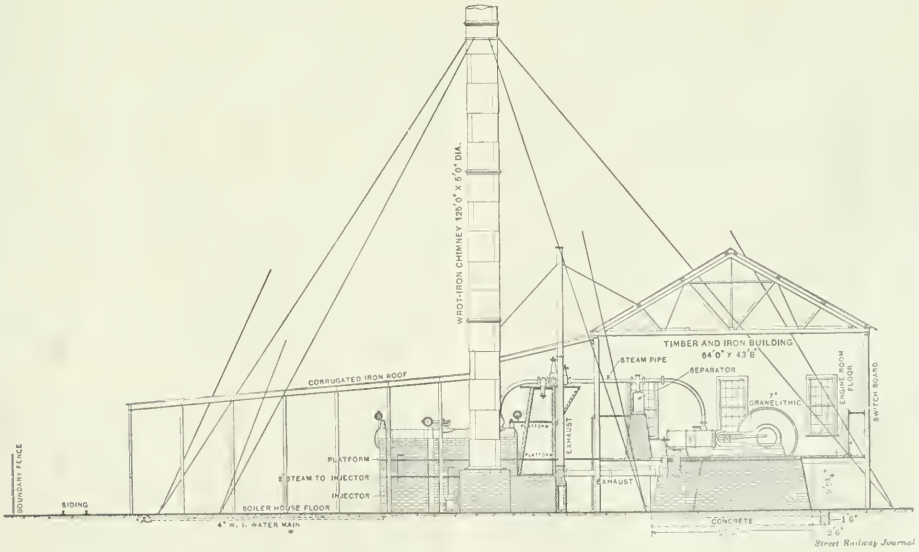
The Ontario Government is sending out ten parties to explore the northern and western portion of Ontario, the first party is under T. B. Speight, Toronto, and the Abitibi river and lake will be the district in which they will work to survey an astronomical line. A. Niven, of Haliburton, will have a party to continue the line of Mr. Speight to Missanabie river. Under the direction of H. S. Davidson, Sarnia, a party will explore the Kabinakagami river down to Moose river and then the Moose river. The party with Wm. Galbraith, Bracebridge, are to start from Jack Fish Bay, go to Long lake, down the Kenogami to Albany river, thence to James Bay. J. M. Tiernan, Tilbury, leads a party from Lake Nepigon up the Ombahika river and down the Albany. The party with James Robertson, Glencoe, will start from Lake Nepigon at Wabinosh bay, through the chain of lakes, across the height of land, down the Albany river and up again to Lake St. Joseph and Savant river and lake. H. B. Proudfoot, of Fort William, is in command of a party to go from Dinorwic on the C.P.R. in the Rainy River district up to Lake Minnietakie and along the Root river taking in all the country. A micrometer and track survey of Sturgeon lake is to be made. David Beatty, Parry Sound, and his assistants explore southwest of Lake Nepigon to Dog lake, and up the Gull river. The country and lakes between Wabigoon and Rat Portage, north of the C.P.R., will be surveyed by the party of T. R. Deacon, of Rat Portage. Demorest and Sylvester, of Sudbury, will explore between Lake Temagami and Montreal river. All of the parties are to explore the different sides of the lakes and rivers and gather information as to general character of the country, timber, minerals, soil, etc.

CANADIAN ENGINES IN WESTERN AUSTRALIA.

Perth is the capital and largest city of Western Australia, with a population of about 36,000. In spite of the size and general prosperity of the city, no tramways of any description had been built previous to the system recently completed. In April 1897, a concession for thirty-five years was granted by the Government to the Perth Electric Tramways, Ltd. No progress was made until September, 1898, when J. G. White & Co., New York, were retained as engineers. They submitted plans for the construction of a line of the most substantial character, which were approved by October 1st, and authority given the engineers to purchase the necessary materials and apparatus, all of which, except crossties, wood poles and cross arms, were shipped from the United States and Canada. Work on the permanent way of the first section, consisting of about five miles of track, was commenced, March 10, 1899, and finished June 15. The concession stipulated that the tramway company was to pave the roadway in the centre of the city for a width of 16 feet with wood block paving. The blocks were of Western Australia jarrah wood, sawn 3-in. x 9-in. x 6-in., and laid on a foundation of concrete 6 inches thick. Owing to the excessive expansion of the blocks during the rainy season, it was necessary to insert "Mastic" joints between them at fixed points. The joints consisted of ribbons or sheets of asphalt and tar to take care of the expansion and prevent buckling. The surface of the roadway on either side of the 16 foot strip was paved in a similar manner by the city authorities. The rails used



Canadian Engines in Western Australia.



Canadian Engines in Western Australia.

through the wood paved sections are 9-in. 84 lb. grooved girder rails, with 36-in. joint plates fastened with twelve 1-in. bolts, and were furnished by the Pennsylvania Steel Co. These rails are spiked to a 3-ft. 6-in. gauge, which is the standard of the Western Australian Government railways, and was specified in the concession. The overhead line work is of wrought iron tubular poles of 4 in., 5 in. and 6 in. sections, furnished by R. B. Corey, of New York. These poles were set in the ground to a depth of 6 feet, and imbedded in concrete. The car house is of brick 204 feet long, 69 feet wide and 18 feet high on the inside between the tops of the rails and bottom cords of the trusses. This building has the first and only roof in Western Australia built of structural steel. The structural work was executed in the shops of the Keystone Structural Company at Roger's Ford, Pennsylvania. Owing to the high freight rates, the trusses could not be shipped in sections as is usually done. They were assembled at the works, all holes reamed in place, the pieces marked with steel stamps, and shipment made in bundles with no two pieces riveted together. As it is possible the company may enter the lighting and power field, it was decided not to erect a permanent building for the power station. The machinery was placed on permanent foundations and a temporary station erected so as not to interfere with the permanent building when it is decided to proceed with it.

The engines are tandem compound, side crank type, and were built by the Robb Engineering Co., Amherst, Nova Scotia. They are 300-h.p. each, and are direct connected to General Electric m.p. 550-volt railway generators, running 150 revolutions per minute. The rolling stock consists of ten 18 foot closed cars of the cross-seat, centre aisle pattern, with a seating capacity of twenty-eight persons, and ten standard closed cars with longitudinal seats. The cross seat cars were built by the J. G. Brill Company, while the others were supplied by the Jackson & Sharp Company. The handling of construction material along the line was exceedingly difficult on account of the poor condition of the roads, which in many places consisted only of loose sand. A great many difficulties were also encountered during the construction of the overhead work, owing principally to the fact that the telephone, telegraph and electric light wires had been put up several years before without any regard to the possibility of a trolley road being built. Nearly all these wires had to be raised the full length of the line, necessitating the setting of longer poles and the transfer of the wires. The head of the tramways company is A. H. P. Stoneham, London, Eng. E. E. Rogers is managing director at Perth, and H. J. Somerset, formerly superintendent of the Winnipeg street railway system, is superintendent.

Industrial Notes.

Maria street bridge, Ottawa, has been pronounced unsafe.

A $15,000 Y.M.C.A. building will be built in Owen Sound, Ontario.

Geo. and Wm. Clark will manufacture woodenware at Sutton, Que.

The Berlin, Ont., Furniture Co.'s new factory will be four stories high

Long and Thompson, Orillia, Ont., are building a large brick foundry.

Sherbrooke, Que., is discussing building a new city hall and public library building.

The Percival Plough and Stove Company, Merrickville Ont., is enlarging its premises.

The Georgian Bay Portland Cement Co., Ltd., has increased its capital from $95,000 to $250,000.

Port Dalhousie, Ont., voted a bonus of $6,500 to the Toronto Rubber Shoe Co., May 21st.

The capital of the Sun Oil Co., Ltd., Hamilton, Ont., has been increased from $15,000 to $50,000.

Jos. Brown, Acton, Ont., will build a planing mill and sash and door factory in connection with his sawmill

Price, Marshall & Co., Ltd, Norton, N.B., will build a confectionery factory, 40 x 90 feet, three stories, at once

Brandon, Man., will probably bonus the Hamburg Mnfg. Co., which proposes to add a sash and door factory to its sawmill.

It is said that Wood, Vallance & Co., Hamilton, Ont., will go into the manufacture of bent wood in Belleville, Ont., on a large scale.

A board fence eight feet high and four miles long is building around the premises of the Dominion Iron and Steel Co., Sydney, C.B.

Brantford, Ont., is discussing the buying of the Gas. Co.'s plant. The probable cost is $100,000. The present earnings of the plant are $19,000.

Watford, Ont., has installed a small Model gas engine, built by Goldie McCulloch Co., Ltd., Galt, Ont., to pump water for street watering purposes.

Goldie, McCulloch Co., Ltd., Galt, Ont., reports quite a satisfactory demand for the Model gasoline engines, and in one week recently shipped eleven of these engines.

Wm. Davis & Son, Cardinal, Ont., will, it is said, require two years to complete their contract for the masonry work of the Quebec bridge.

W. Bremner, C. H. Crowe, F. Crowe, D. A. Gordon, Rachael Badder, Wallaceburg, Ont., have been incorporated as the Riverside Canning Co., Ltd., Wallaceburg, Ont.; capital, $50,000.

Gardner Bros, handle manufacturers, who lost their mill in Leamington by fire some time ago, are moving to Walkerville, Ont, where they will occupy the building formerly used as a basket factory.

Exeter, Ont., has bought a 6-h.p. Model gasoline engine and a 4 x 6 triple power pump from the Goldie, McCulloch Co., Ltd., Galt, Ont., to be used to fill the fire tanks and supply the water necessary for street watering.

The machinists employed by the Fensom Elevator Works, Toronto, received an advance of 12½ per cent. last month. The advance had not been asked for by the men, and is an evidence of the prosperity of this well-known firm.

A. C. Petersen, W. H. Sumbling, C. E. Jarmain, Toronto; J. Smale, North Toronto; H. E. Bydwell, Montreal, have been incorporated as the York Laundry Machinery and Supply Co.; head office, Toronto; capital, $40,000.

E. W. B. Snider, W. W. Snider, St. Jacobs, Ont.; H. W. Anthes, L. L. Anthes, Toronto, and C. W. Snider, Waterloo, Ont., have been incorporated as the Toronto Foundry Co., Ltd.; head office, Toronto; share capital, $50,000.

Ten years ago the Nova Scotia Steel Co., Ltd., reduced wages ten per cent.; last year the old rate was restored, and in October an advance of five per cent. was granted, and a month ago a further rise of nine per cent. took place.

J. Curry, T. McLaughlin, A. Bates, W. Maguire, E. H. Hilborn and W. C. Price, Toronto, and T. H. Goodison, Streetsville, Ont., have been incorporated as the Canadian Steam Carriage Co., Ltd.; head office, Toronto; share capital, $250,000.

The bylaw to guarantee the debentures of the G. McLagan Furniture Co., of Stratford, Ont., to the extent of $30,000, has been passed. The factory will be 250 feet by 40 feet, of brick, four stories high, to cost $40,000, and will employ on an average 150 men the year round.

C. D. Cramp, W. M. Cramp, Philadelphia, Pa.; A. H. O'Brien, H. M. E. Evans, Ottawa; A. McLean Macdonell, F. A. Anglin, J. A. Currie and Neil McLean, Toronto, have been incorporated as the Cramp Ontario Steel Co., Ltd.; head office, Collingwood, Ont.; share capital, $5,000,000.

Firstbrook Bros., manufacturers of packing boxes, etc. Toronto, have bought the factory and premises of the Midland Box, Shook and Planing Co., at Dollartown, near Midland, Ont. Extensive alterations and additions are to be made to the plant, which is to be run in connection with that in Toronto

The combination of the leading stovemakers of Canada is said to now be practically complete. All the large manufacturers except the Gurney Co., Ltd., of Toronto, have, it is said entered the trust. The damage to local interests in many places will be very great, but compensating advantages in the way of cheapened production may be obtained

A building to contain the science classes in connection with the Truro, N. S., Normal School, is to be built.

The Canada Mining and Metallurgical Co., Ltd., is applying for the enlargement of its capital stock to $10,000,000.

Port Hope, Ont., has carried a bylaw to raise $20,000 for extension and improvement of the waterworks system.

It is proposed to buy the Athletic Club building and grounds on College street, Toronto, for the Technical School.

J. H. Hall, who recently resigned his position as superintendent of the Wortman & Ward foundry, London, Ont., has removed to Brantford.

It is proposed to locate at Sandwich, Ont., a number of the large Michigan sawmills that are being driven out of that country through lack of material.

J. W. Munro, T. Mackie, W. Russel, jr., C.E.; J. R. Lockhart and J. G. Forgie, Pembroke, Ont., are being incorporated as the Alumette Oil Co., Ltd., to develop the oil finds reported from the Pembroke district some time ago.

The city engineer of Halifax, N.S., recommends the adoption of water metres to prevent waste, as the present water supply is found insufficient, and an increased supply could only be had at an enormous expense.

It is understood that the contract for the erection of the new Canadian Pacific Ry. station at Ottawa, has been given to T. Thompkins, Brockville, who built most of the Canadian Pacific Ry. stations in the Northwest and British Columbia, as well as the Hotel Vancouver, belonging to the same company.

Prescott, Ont., has given the Imperial Starch Co., Ltd., a site, valued at $8,000, and tax exemption for twenty years. The town also agrees to furnish the company electric energy for one hundred lights and supply them with one hundred thousand gallons of water daily free of charge, for the period of twenty years. In return for this the company will grind 1,000 bushels of corn daily.

The Edmund Hall Co., Alpena, Mich., U.S., has bought the property on the bay shore at Sarnia, Ont., from Nelson north to Exmouth street, about 800 feet frontage, and extending from the Grand Trunk track westward across the bay and across Sand Point to deep water in the River St. Clair. Here extensive saw mills, to employ a couple of hundred men, will be built. This is one of many such transfers of industry from Michigan to Ontario, the result of the present timber policy of the Ontario Government.

James Cowan, ex-Dominion Arbitrator, died at his residence, Craigie Lea, Galt, Ont., May 22, in the 98th year of his age. Deceased was born near the Vale of Yarrow in 1803, and has been a resident of Galt and vicinity since 1834. The late Thomas Cowan, postmaster at Galt, was a son of deceased. The surviving members of the family are J. Lang Cowan, residing at Clochmor, the farm homestead near Galt; William Cowan and A. B. Cowan, of the firm of Cowan & Co., Galt, and Miss Cowan at Craigie Lea.

The Municipal Technical School, Manchester, Eng., has ordered from the Robb Engineering Co., Amherst, N.S., a 150 h.p. tandem compound engine, to be directly coupled to dynamo, from Dick, Kerr & Co., London, Eng., for electric lighting. The order was given on the recommendation of Dr. J. T. Nicolson, professor of engineering, who was formerly at McGill University, and the purchasers state that this engine is to be placed with other engines of the leading British makers as an example of the best English and foreign practice in engineering, which is certainly a very great compliment to our enterprising friend the Robb Engineering Co.

In gathering information for the Historical Mining Series to commence in The Herald, says The Marmora Herald, May 10th, we have unearthed a few yards from our door, where the old furnace stood, a fire-brick and piece of partly smelted iron. They are now placed in our office window. The bricks were imported from England and cost laid down here 20 cents per pound. They are stamped "Farnley Iron Works, Wortley, Leeds." Each brick is numbered and they are of different shapes and sizes to fit in the proper places in the furnace. Considering that they were imported in 1820, they are of considerable interest.

A school building to cost $30,000, will be built at Sydney, C.B. C. B. Chappell, Charlottetown, P.E.I., is architect.

The building of a $50,000 hotel is now going on at Springbank, a suburb of London, Ont.

Sussex, N.B., is sinking a trial artesian well. If a satisfactory flow is secured, wells sufficient for the water supply of the town will be sunk and a waterworks system installed.

Moore & Henry, architects, London, Ont., have taken out a permit for the new Masonic Temple to replace that burned some time ago.

A creamery with a daily output of 12,000 pounds of butter is shortly to be established in Ottawa, Ont., it is reported. The capital of the company that has been organized is $25,000.

Smith's Falls, Ont., will lay granolithic sidewalks this season. Willis Chipman, C.E., will act as consulting engineer to the town in the improvements now going on.

The Maritime Anchor Wire Fence Co., Truro, N.S., has a contract to supply the I.C.R. with 50 miles of fencing to be used in Nova Scotia.

Cornwall has just paid $110,000 for the waterworks taken over from the company which put them in. The matter has been in litigation for three years, and the costs have been $22,000.

The Montreal Harbor Commissioners have accepted the proposal of the Connors' syndicate to build a one million instead of a three million bushel elevator. The remaining storage capacity is to be supplied by warehouses.

The Woods Motor Vehicle Co., of Buffalo, N.Y., was incorporated in the State of New York, May 29th. Its capital stock is $300,000. The directorate, besides being composed of Buffalo and New York capitalists, includes the names of D. Rankine, Niagara Falls, and Fred. Nicholls, Toronto, Ont.

The Schofield Woolen Co., which recently lost a large portion of its premises in Oshawa, Ont., by fire, is said to be open to offers to locate in some other town if sufficient inducements are secured. St. Thomas, Ont., is making an effort to secure the industry.

The Britannia Company of Colchester, Eng., makers of nearly 300 varieties of engineers' tools, etc., announce that they are open to appoint a sole agent in Canada; and they are also prepared to act as English agents for a first-class Canadian firm in engineers' specialties.

A fire bylaw affecting the entire city of Hull, Quebec, has been adopted by the Hull city council. By its regulations all dwellings, stores, and factories erected in the city in the future must be fireproof. All sheds, stables, outbuildings, if built within 60 feet of a street, must also be made proof against fire.

Hon. R. R. Dobell has notified the Mayor of Levis, Que., that the projected works at that place will be commenced without delay. They will cost at least $300,000 and include the construction of a new station, the conversion of the old one into post and customs offices, and the building of wharves to permit the largest steamers to discharge and take cargo at Levis.

B. Shepherd, J. E. Aldred, H. Semple, L. B. Copeland, R. W. Douglas, Montreal, have been incorporated as the St. Maurice Water Supply Co., Ltd.; capital stock, $25,000; headquarters at Shawinegan Falls, Que.; to furnish water, not including water power, to the people of Shawinegan Falls, and adjoining municipalities.

H. McC. Hart, R. E. Harris, Halifax, N.S.; E. Dickie, Upper Stewiacke, N.S.; E. P. Allison, Halifax; N. H. Stevens, H. J. Stevens, Ada J. Stevens, J. A. Walker, Chatham, Ont.; Jas. Rutherford, Blenheim, Ont., are being incorporated as the Canada Flour Mills Co., Ltd.; capital stock to be $650,000; chief place of business, Halifax, N.S.

An important industry is promised from the incorporation of the Grey & Bruce Portland Cement Co., of Shallow Lake, Ont., with a capital of $190,000, head office, Owen Sound, with the following provisional directors: J. McLauchlan, J. George, J. H. Spence, J. Young and J. E. Campbell. The objects of the company are to quarry, manufacture and sell Portland cement, putty, tiles, bricks and such material.

The bicycle manufacturing carried on by the Canada Cycle & Motor Company at the Welland-Vale Works, St. Catharines, Ont., will be continued in Brantford. The St. Catharines works, which were burned last month, will not be rebuilt.

The Canadian Steel Co., Welland, Ont., held its first meeting in Toronto, May 15th, when E. A. C. Pew was elected president, and L. E. Hinckley, New York, vice-president of the company. Mr. Hardebeck was appointed secretary pro tem. The selection of directors was not completed. E. M. Butz & Co., Pittsburg, Pa., engineers and architects, will have charge of the construction of the plant.

The Bethlehem Steel Co., Bethlehem, Pa., recently invited the superintendents of the leading United States machine tool makers to witness a test of the new steel which it is using for lathe tools. If the facts shown by the test can be brought into use on a commercial scale it will revolutionize the machine shop practice of the world. It was shown on steel cylinder cutting off work the lathe could be speeded up to three times the speed of the best present machine practice. We shall watch the future development of this new steel.

The Newfoundland Railway, which crosses the island colony and has a mileage of some 600 miles, and which is owned and controlled by R. G. Reid, Montreal, may soon pass into the hands of a company, together with the fleet of coastal steamers and telegraph services. He also owns the electric street railway in St. John's, and has a monopoly of the greater part of the minerals of the colony, together with extensive pulp areas and timber limits. Mr. Reid is now endeavoring to float a company with a capital of $27.000,000 to take over all his belongings, rights and franchises, and conduct and operate the same. It is understood that the greater part of the capital can be obtained in England, but before the scheme can be accomplished it is necessary for Mr. Reid to have the sanction of the Newfoundland Government. Mr. Reid will leave for St. John's in a few days.

Electric Flashes.

Robert Bell, electrician for the Welland, Ont., Electric Light Co., has resigned.

The Guelph, Ont., street railway will shortly be connected with the C.P.R. there.

Strathcona, N.W.T., will vote on a bylaw to spend $2,000 on a municipal lighting plant on the 12th inst.

The municipality of Winnipeg has offered $100,000 for the commercial lighting plant, which it is anxious to municipalize, the experiment of street lighting having turned out so well.

D. S. Perrin & Co., biscuit makers, London, Ont., have ordered a 50-k.w. generator from the Electrical Construction Co., London, Ont.

Brockville is taking steps to buy out the electric lighting and gas plants with a view to civic control. Willis Chipman, C.E., is making a report on the value of the plants for the town.

W. E. H. Massey has installed a plant sufficient to light all the buildings on his farm at East Toronto, Ont., and supply necessary power, and also to light the village; the municipality proposes to buy current from him and install its own lamps.

The Electrical Construction Co., Ltd., London, has recently received orders for nine motors of various sizes from its agent in Montreal, and five from its Winnipeg agent, and four from Toronto.

W. H. Meldrum, J. H. Fisher, J. Walker, J. McL. Hall, J. R. Inksater, P. H. Cox, R. L. Murray, T. Shawcross and G. B. S. Jones, Paris, have been incorporated as the Paris Electric Light Co., Ltd.; capital stock, $20,000; chief place of business, Paris, Ont.

J. A. F. McCabe, J. A. Begin, E. A. McCone, L. Duchesneau, M. Bourassa, Windsor Mills, Que., and H. A. Meagher, M.D., Montreal, have been incorporated as the Windsor Electric Co., Ltd.; capital stock, $24,000; to supply heat, light and power in Windsor Mills, Que.

St. Louis, a suburb of Montreal, is preparing a by-law to annul the franchise in that municipality of the Montreal Park and Island Ry. Co., as a result of a Superior Court judgment.

The Hamilton city council has granted permission to the Cataract Power Co. to run freight cars, coming in from Dundas, at certain hours through its streets. Express cars containing perishable goods may be run at any hour.

The Greenwood & Phoenix Tramway Co. has been organized for the purpose of building a tramway line from Greenwood to Phoenix with branches into Deadwood, Wellington and Summit camps, B. C. The line will connect with the Great Northern Railway.

Jas. Milne has reported on the proposed Cannington, Ont., Fenelon Falls, Ont., power plant, as costing at least $18,500, and he states that he is unable to find evidence of there being sufficient water for the proposed development.

The Cataract Power Co. is extending its power line from the Victoria avenue transforming station, Hamilton, to the village of Burlington. It is the intention of the company to furnish electric light for the new Hotel Brant, and it may undertake a contract to light the entire beach.

The Voltage Storage Battery Co.'s new factory in Lottridge street, Hamilton, will be occupied this month. This company is now shipping to Canton, Pa., a storage battery of a capacity of 1,000 ampere hours, and another large battery is being made for export to Peterboro, New Hampshire.

The widow of Geo. Peace is suing Montreal for $10,000 damages for herself and minor children, consequent upon the death of her husband, who was killed by an electric shock at the incinerator, on November 10th last, while moving garbage with an iron bar which came in contact with the wire of an electric light. Negligence on the part of the city is alleged.

The Canadian Electrical Association will not hold its annual convention in Ottawa in June, as intended, owing to the destruction of so many of the electric plants in the recent fire. The executive committee will appoint a time, and also a place if later on Ottawa is found to be still unable to afford sufficient points of interest for the convention, which will probably be held in September.

The Cataract Power Co., of Hamilton, is now installing two new dynamos at their power station, DeCew's Falls. The new machines will have a capacity of 2,000-k.w. each with an overload capacity of 3,000-k.w. These will be ready in August, and will increase the capacity of the plant from 3,000 h.p., which was all that Hamilton was expected to require for some time to come—to 10,000 h.p. The company's business, therefore, has already gone beyond the anticipations of its promoters.

Some Chicago men, D. S. Wegg, J. P. Wiborg, G. K. Clutton, W. H. Dayton and G. H. Pope, have been incorporated as the Anglo-American Power Company, Ltd., with a share capital of $5,000,000, to acquire the Jenison water powers franchise on the Kaministiquia river, near Port Arthur, Ont. The company is empowered to sell and distribute power, compressed air, electricity, or power in any form developed from these properties. It is this enterprise to which Port Arthur looks to make it a great manufacturing centre.

The Electrical Construction Co., Ltd., London, Ont., reports the following sales recently made: George May & Sons, Ottawa, Ont., one 5-h.p. motor; C. D. Burdick & Co., London, Ont., one 10-h.p. motor; the London, Ont., Pant and Overall Co., one 6-h.p. motor; E. Parnell, London, Ont., one 8-h.p. motor; J. P. Archibald, Ingersoll, Ont., one 15-h.p. motor; Timbell & Co., London, Ont., one 3 h.p. motor; C. Kennedy, London, Ont., one 3-h.p. motor; H. W. Petrie, Toronto, Ont., one 12-h.p. motor; F. Raney, Kingston, Ont., one 8 h.p. motor; W. Carson, Kingston, Ont., one 3 h.p. motor; N. H. Good, Berlin, Ont., one 3 h.p. motor.

The Chambly Water & Power Co. is about to add very largely to the present plant at Chambly, Que., and before long there will be developed some 30,000 h.p. The present plant is now furnishing 7,500 h.p. The development of an additional power at St. Therese Rapids, some three miles up the river from the present plant, will be undertaken. Peter Lyall has the contract for additional masonry, and when this is completed and the electrical plant installed the works will be capable of developing 20,000 h.p. The new works, which it is proposed to erect at the St. Therese Rapids, will when fully developed give an additional 10,000 h.p.

Marine News.

The Hamilton Steamboat Company's steamer "Mazeppa" has been sold to John McLachlan, Owen Sound, Ont.

Knapp's roller boat is still navigating its inventor's brain, if no other element, and he is reported to be about to build a new boat for Montreal capitalists, who are interested.

A new cargo steamer of 7,000 tons capacity has passed into the hands of the Allan Line. It is to be named the "Ontarian," and will be employed in the service between Liverpool and Montreal.

The Dominion Line has ordered some larger steamers. The latest addition to the fleet was the New England, of 11,406 tons, but there are now on the stocks to its order two sister vessels (one to be called the "Commonwealth"), which will each have a tonnage of 13,000. The vessels are for the Boston route.

Dredge No. 4, built by Carriere, Laine & Co., Point Levis, for the Montreal Harbor Commissioners, is successfully at work. The new dredge has a steel hull and boom, and in general appearances looks the same as the other dredges, but is much more powerful.

The New York State Legislature has passed an Act to remove the limit of $50,000, above which no company might capitalize which did business on the Erie Canal. This will increase the capacity of the canal considerably by introducing more improved methods of transport, handling, etc.
